At the hearing before the Interstate Commerce Commission at Peoria, Ill., on July 14 evidence was introduced by the Chicago, Ottawa & Peoria Railway that it was an interstate carrier and engaged in the business of handling freight, passengers and express in interstate commerce; that it had entered into negotiations with steam railroads to be joined as party defendants for obtaining through routes and through joint rates in connection with these several defendants, so that traffic originating upon or consigned to points and industries on the line of the Chicago, Ottawa & Peoria Railway could be handled in connection with these lines. It appeared from the testimony that under present conditions it is impossible for a shipper to ship his product satisfactorily over the Chicago, Ottawa & Peoria Railway, as in most cases the shipper would have to pay the full local rate to the point of interchange with the steam line and the local rates from such point of interchange to the point of destination.

Among the principal shippers represented at the hearing were A. Bryant & Sons Nursery, Princeton; C. A. Omen Lumber & Coal Company, Princeton; Morris Grain Company, Morris and Wilson Siding, Ill., and the General Roofing Manufacturing Company. All of these shippers testified that they were either entirely dependent upon the Chicago, Ottawa & Peoria Railway for handling their business, inbound and outbound, or were penalized by the lack of through routes, being compelled to pay a switching charge or cost of hauling their traffic from 1 to 3 miles to the nearest steam railroad station. It was shown by the testimony of these witnesses that in case through routes and joint rates were put into effect, the shippers would save several thousand dollars a year in switching charges and the cost of hauling. It was also brought out that in certain instances the steam lines had stated as their reason for refusing to establish through routes as requested that they had no interchange relations with railroads operated by electricity.

The matter will be taken under advisement by the commission. Both parties have been required to submit briefs. It is not expected that the case will be determined by the Interstate Commerce Commission before late in the fall.

Interurban Traffic in Milwaukee

Statistics of the Milwaukee Electric Railway & Light Company for 1913 and 1914 show the following average daily number of interurban cars operated in and out of the Public Service Building, Milwaukee, Wis., by months:

	1913	1914
January	242	232
February	244	226
March	246	230
April	252	242
May	296	316
June	400	328
July	418	380
August	400	...
September	332	...
October	278	...
November	246	...
December	232	...

The maximum number during any day during 1914 was 548.

Rhode Island Company Denies Fare Increase Is Excessive

The Rhode Island Company, Providence. R. I., has filed with the Public Utilities Commission of Rhode Island its answer to the complaint of the City Council of Woonsocket against the Woonsocket Street Railway relative to the fare charged between Manville and Fairmount. The company admits that it charges two 5-cent fares but denies that the distance between Manville and Fairmount is approximately 5 miles and avers that the distance is 7.57 miles. It admits that a 5-cent fare is collected between Manville and a point in Main Street near the center of Woonsocket and says that for passengers who have come from points beyond the limits of Woonsocket another fare is charged from Woonsocket to Fairmount. It avers that passengers boarding cars in Woonsocket are charged only one 5-cent fare in the Woonsocket, Cumberland line and Fairmount district, 4.84 miles. In short, the company contends that the conditions surrounding the Fairmount line will naturally adjust themselves when the territory is developed sufficiently and that owing to recent increases in operating expenses, due particularly to the new scale of wages granted to employees in July, 1913, and the recent renewal of tracks in Woonsocket and elsewhere, much of which was renewed not because of its poor condition but because of municipal requirement, the company is in a position where it can ill afford to grant or meet concessions that would in any way reduce its revenues.

Rock Island Southern May Use Terminal.—The Illinois State Public Utilities Commission has ruled that the Chicago, Burlington & Quincy Railroad has no right to exclude the Rock Island Southern Traction Company from terminal facilities at Galesburg, Ill.

Reduction in Fare in Marquette.—The Marquette City & Presque Isle Railway, Marquette, Mich., began the sale of six tickets for 25 cents on Aug. 2, in accordance with the terms of the ordinance under which it operates. The company has charged a straight 5-cent fare for the last five years.

Peculiar Heat Prostration in Louisville.—Overcome by the recent heat in Louisville, Ky., reaching 112 deg., a motorman on a Bank Street car of the Louisville Railway fainted. His car ran nearly a block before an inspector who chanced to be on board noticed that the motorman was incapacitated and stopped it. No harm was done to the passengers of the car.

New Ticket Plan on Connecticut Line.—The Hartford & Springfield Street Railway, Warehouse Point, Conn., has decided to give a six months' trial to the plan of selling a book of 100 tickets for $5 without regard to any time limit. These tickets will be issued to each patron individually and will be non-transferable and good until used. They will be on sale in each community served by the company and it will also be possible to obtain them by application to the conductors.

Increase in Average Length of Car Service.—A new schedule for the Mahoning & Shenango Valley Railway has been approved by the City Council of Youngstown, Ohio, and an ordinance will shortly be introduced to make it effective. Under this schedule the average length of service of all cars on all lines will be twenty hours and forty-eight minutes, or eighteen minutes longer than before. This is one of several changes being made by the railway to improve the local service.

Railway Men as Automobile Spotters.—Charles S. Hubbard, director of public safety of Pittsburgh, Pa., wrote a letter recently to P. N. Jones, general manager of the Pittsburgh Railways, suggesting a plan of co-operation by which the operating employees would aid the police by reporting the numbers of automobiles operated by drivers who persist in running by street cars which are taking on or discharging passengers, or who otherwise take chances which endangers the lives of persons in the automobiles or the passengers on the cars.

No Excess Fare on Brooklyn Rapid Transit.—The Brooklyn (N.Y.) Rapid Transit Company has been ordered by the Public Service Commission of the First District of New York to cease collecting an extra nickel from Rockaway Beach passengers who fail to buy through tickets. Such passengers are charged 5 cents to pass through the turnstiles, and then a 15-cent fare to Manhattan. The company is ordered to stick to the 15-cent rate, the commission holding that the law providing that steam railroads may collect excess fare when tickets are bought on a train does not apply to rapid transit lines.

Decrease in Electric Railway Fatalities.—The report of the National Highways Protective Society shows that 141 children were killed by vehicles in the streets of New York City since Jan. 1; twenty-three of them during July. Since the first of the year automobiles killed seventy-five children, trolleys twenty and wagons forty-six. Street fatalities in July totaled forty. Col. Edward S. Cornell, secretary of the society, says that electric railway fatalities are decreasing. Deaths by vehicular traffic in Manhattan are the lowest since July, 1908, but in Brooklyn there has been an increase, especially in automobile fatalities.

Opinion Concerning Regulation of Seats for Passengers.—David O. Mastings, city solicitor of Wilmington, Del., has rendered an opinion to the City Council relative to a pending ordinance requiring electric railways to provide seats for all passengers. Mr. Mastings states that if any city body has jurisdiction in the premises it is the Board of Public Utility Commissioners and not the City Council. In his opinion the commission can enact such regulation if reasonably drawn. He is of the same belief relative to a section of the ordinance prohibiting waits of more than ten minutes between cars, but in each case contingencies would have to be provided for.

Illinois Traction System Employees' Picnic.—The employees of the Illinois Traction System, Peoria, Ill., and of the Urbana & Champaign Railway, Gas & Electric Company, a subsidiary utility, held their annual all-day picnic on July 23 at Homer Park. About four hundred persons, mostly employees and their families, were present. They were transported to the picnic grounds in seven interurban cars, which left Champaign at 9 a. m. and returned at various times during the evening. The picnic was in charge of H. J. Pepper, general superintendent of the Urbana & Champaign Railway, Gas & Electric Company, and the expenses were paid by the Illinois Traction System.

Reduction in Duluth Fare Upheld.—Judge Stevens in the Circuit Court of Dane County has affirmed the order of the Railroad Commission of Wisconsin requiring the sale of six tickets for 25 cents by the Duluth-Superior Traction Company in Duluth. The company contended that the 5-cent fare was stipulated in the franchise and could not be revoked by the Railroad Commission. Judge Stevens cited the Milwaukee fare case in overruling this order and added that "the wording of the Superior franchise more clearly indicates that the provision as to a 5-cent fare is merely a limitation on the amount of the fare that may be charged than did the language under consideration in the Milwaukee case."

Cannonball Express on Interurban Line.—Officials of the Chicago, South Bend & Northern Indiana Railway, South Bend, Ind.; the Union Traction Company of Indiana, Anderson, Ind.; the Winona Interurban Railway, Warsaw, Ind.; the Southern Michigan Railway, South Bend, Ind.; the Benton Harbor & St. Joseph Railway & Light Company, Benton Harbor, Mich., and the Wells-Fargo Express Company decided at a recent conference in Warsaw to institute on Aug. 2 the "Cannonball Express," a limited interurban fast freight between Indianapolis, Ind., and Benton Harbor, Mich. Through express cars leave Indianapolis at 7 p. m. and arrive at Benton Harbor at 10.30 a. m. the next day. Trains leaving Benton Harbor at 5 p. m. arrive at Indianapolis at 5.10 the next morning. This is said to be the fastest interurban service of its kind in the Central West.

Changes in Fare Ordered on Long Island Line.—The Public Service Commission of the Second District of New York, has issued an order requiring certain changes in fares on the New York & Long Island Traction Company's lines through Floral Park, New Hyde Park, Garden City Estates North, Mineola and vicinity. The commission has ordered the company to extend its local fare limit in New Hyde Park to Seventh Street. The commission has also ordered the company to sell its return trip tickets between Mineola and the New York City line on its cars or else to provide more agencies for their sale. At present there are agencies in Mineola and in Floral Park, but all persons boarding the cars at other than these points cannot avail themselves of the 15-cent return rate. The company is given thirty days to decide which of these alternatives for the further sale of round-trip tickets it will accept, and the case in this respect is kept open. The order of the commission becomes effective on Aug. 15.

Suspension of Proposed Fare Increase Ordered.—The Public Service Commission of Massachusetts has issued an order suspending the proposed change in the rate of fare for passengers on the Middlesex & Boston Street Railway, Newtonville, Mass. The proposed change in the fare was to have become effective on Aug. 3, 1914, as follows: 6 cents for every ride between any two fare limits, wherever situated, with an additional charge of 1 cent for every transfer issued. The commission has ordered that the operation of the new schedule be suspended and that the use of the new rates an charges be deferred until Oct. 1, 1914, unless otherwise ordered by the commission. The request by the company to be allowed to raise its tariff came as a result of the recent dispute between the line and its employees, and the decision of a board of arbitration that the carmen are entitled to a 15 per cent raise and back pay from June 1, 1913. It is estimated that the award will cost the company about $25,000 for back pay and about the same amount each year in addition to the amount heretofore paid for wages.

Express Service in District of Columbia.—The Public Utilities Commission of the District of Columbia has received requests from the public and applications from the street railways to install express service on certain lines. Conferences were held with representatives of the companies with a view to removing certain objections made by the public to the present methods of operating express cars in the District of Columbia. The commission says that the object of express service on a line is to segregate short-haul and long-haul passengers during the rush hours of traffic and that the necessity for this class of service exists only in the case of traffic on interurban lines from the center of the city towards the suburbs and on suburban lines. A trial was made of express service on the routes and under the conditions specified by the commission, and as this trial resulted in an improvement in the service and the companies concerned expressed their satisfaction with the provisions of the order establishing the experimental service, the commission has modified the order and made it a permanent one.

Massachusetts Commission on Car Equipment.—The Massachusetts Public Service Commission has issued a statement upon the petition of the executive committee of the conference board of street railway employees of Massachusetts relative to the equipment of cars with suitable wheelguards, fenders, heated glass vestibules and air brakes. The commission points out the tendency to equip all except light cars operated at slow speeds with air brakes and the use of fenders under the supervision of the board. With respect to heated vestibules and glass wind shields, the commission states that it would not be justified in requiring companies to furnish facilities for heating all car vestibules in winter or in providing glass vestibules or wind shields on all open cars. It appears that while very few vestibules are heated, a number of companies have provided wind shields on many of their open cars, and there are some long-distance high-speed lines on which heated vestibules on box cars in the winter and wind shields or glass vestibules on open cars in the summer may be required. The commission informs the petitioners that it will continue its studies along this line.

Hearing on Berkshire Street Railway Fares.—A hearing was held by the Massachusetts Public Service Commission at Boston on July 28 upon the petition of the town of Cheshire for a reduction in fares between Cheshire and Pittsfield on the Berkshire Street Railway, Pittsfield, Mass. Criticism was directed against the existing 15-cent fare in comparison with a 10-cent fare in force between Cheshire and North Adams during morning and afternoon rush hours. Bentley W. Warren, for the company, pointed out that on some parts of the line the fares are already too low. Cheshire has a population of 2000, and the fares are about 1.5 cents per mile on the Berkshire system. Mr. Warren contended that this rate is not too high. The steam railroad fare between Cheshire and Pittsfield is 20 cents. Outside of so-called workingmen's hours the fare to North Adams is 15 cents. Commissioner Anderson said that where only a few persons travel a higher fare is a necessity. He suggested the desirability of operating workingmen's cars into and out of Pittsfield morning and night. Mr. Warren brought out the point that the company is about to attempt a revision of fares over its system as a whole, and urged the commission to permit a trial at the new rates before ordering a change on the basis of the petition. The company also intends to take up the question of safeguarding its high-tension line construction in Cheshire, and is endeavoring to reduce the noise of the rotary converters in its local substation. In closing the hearing, Commissioner Anderson favored postponing action until the above changes have been effected.

Personal Mention

Mr. Thomas L. Wolfe has resigned as acting rate clerk of the Illinois State Public Utilities Commission.

Mr. Frederick J. MacLeod has been elected chairman of the Public Service Commission of Massachusetts.

Mr. C. A. Smith resigned recently as auditor of the Chicago, South Bend & Northern Indiana Railway, South Bend, Ind.

Mr. W. F. Breese has recently been appointed master mechanic of the Columbus (Ga.) Railroad, to succeed Mr. H. K. Jarvis.

Mr. A. C. Mann has succeeded Mr. J. C. Kuhns as purchasing agent of the Kensington & Eastern Railroad, Chicago, Ill.

Mr. H. G. Kessler has been appointed auditor of the Springfield (Ill.) Consolidated Railway, to succeed Mr. J. Benedict.

Mr. R. A. Clark has been elected treasurer of the Waterbury & Milldale Tramway, Waterbury, Conn., to succeed Mr. E. S. Todd.

Mr. W. T. Lamb has been appointed auditor of the Galesburg & Kewanee Electric Railway, Kewanee, Ill., to succeed Mr. W. H. Epps.

Mr. W. O. Hoover has been appointed secretary of the Center & Clearfield Railway, Phillipsburg, Pa., to succeed Mr. F. E. Taylor.

Mr. J. C. Morton has been appointed chief engineer of the Pacific Power & Light Company, Astoria, Ore., to succeed Mr. D. F. McGee.

Mr. L. W. Jacques has resigned as master mechanic of the Rockford & Interurban Railway, Rockford, Ill., to engage in other business.

Mr. J. M. Anderson has been appointed chief engineer of the power station of the Pensacola (Fla.) Electric Company, to succeed Mr. H. Harley.

Mr. A. N. Pearce has been appointed superintendent of the Center & Clearfield Railway, Phillipsburg, Pa., to succeed Mr. H. J. Thompson.

Mr. J. E. Vaughn has been appointed purchasing agent of the Shore Line Electric Railway and the Norwich & Westerly Traction Company, Norwich, Conn.

Mr. W. H. Acker, formerly electrical engineer of the Shenango Railway & Light Company, Youngstown, Ohio, has been appointed transmission engineer of the West Penn Traction Company, Pittsburgh, Pa.

Mr. W. W. Waterson has been appointed superintendent of the Peoria division of the St. Louis, Springfield & Peoria Railroad, included in the Illinois Traction System, with headquarters at Mackinaw Junction, Ill.

Mr. H. S. Curry has been appointed chief dispatcher of the Illinois Traction System, with headquarters at Staunton, Ill., to succeed Mr. Edward R. Heine, who has been promoted, as noted elsewhere in this column.

Mr. A. S. Bergschneider has been appointed superintendent of the Illinois Central Traction and the Bloomington, Decatur & Champaign Northern Divisions of the Illinois Traction System, with headquarters at Decatur, Ill.

Mr. E. N. Sanderson has been elected president of the Tucson (Ariz.) Rapid Transit Company to succeed Mr. C. C. Chappelle. Mr. Sanderson has also been elected president of the Hot Springs (Ark.) Street Railway, to succeed Mr. C. C. Chappelle.

Mr. B. E. Bramble, general auditor of the Illinois Traction Company, Champaign, Ill., has also been appointed general auditor of the Western Railways & Light Company, Champaign, Ill., succeeding Mr. W. J. Achelpohl, who has been appointed to another position with the same companies.

Mr. F. R. Edmonston has been appointed superintendent of transportation of the Illinois Traction System, Peoria, Ill., having jurisdiction over all lines west and north of Decatur, and south of Springfield, with headquarters at Springfield, Ill.

Mr. W. J. Achelpohl, general auditor of the Western Railways & Light Company, has resigned that position to become supervisor of operating expenditures of both the Illinois Traction Company and the Western Railways & Light Company.

Mr. Edward R. Heine has been appointed superintendent of the Springfield and the St. Louis divisions of the St. Louis, Springfield & Peoria Railroad, included in the Illinois Traction System, with headquarters at Staunton, Ill., succeeding Mr. J. C. Ferritor, resigned.

Mr. C. E. Warwick has resigned as superintendent of the Fort Wayne & Northern Indiana Traction Company's city lines in Fort Wayne, Ind., to become superintendent of the railway department of the Vicksburg Light & Traction Company, Vicksburg, Miss., which is controlled by the Ellison-Clifford Company.

Mr. George U. G. Holman, New York and Boston, recently resigned as an officer and director in the South Fork-Portage Railway, Johnstown, Pa., though retaining a substantial interest in the company. Mr. Holman will take a rest before engaging in any other undertaking. He promoted and nearly completed the construction of the road mentioned and it will be finished by local interests.

Mr. Ludwig Spängler, director of the Vienna Municipal Tramways, has been elected vice-president of the Austrian Association of Local & Light Railways. Mr. Spängler is a keen student of American transportation practice, the Vienna tramways being the first European railway to operate cars with separate passages for entrance and exit. At the present time Mr. Spängler is conducting some interesting experiments with double-deck and electric trailer operation.

Mr. George W. Bishop, who retired recently as a member of the Public Service Commission of Massachusetts, has been appointed chief of the inspection bureau of the commission. In the eighteen years that he sat as a member of the Railroad Commission and then for thirteen months more as a member of the Public Service Commission, Mr. Bishop gave special attention to the physical inspection of railroads and street railways. He has also traveled extensively at home and abroad to study railroad building and upkeep. The inspection bureau of the commission is now more distinctly a department than it has been before. It has been considerably enlarged since the creation of the Public Service Commission.

Mr. R. L. Caldwell has been appointed superintendent of the Warren-Bisbee Railway, Warren, Ariz., to succeed Mr. Jesse Yoakum. Mr. Caldwell was formerly superintendent of transmission line construction for the Black Mountain Mining Company, Magdalena, Sonoro, Mexico, and assistant manager of the Bisbee (Ariz.) Improvement Company. He later became superintendent of construction for the Warren Company during the building of the Warren-Bisbee Railway, and afterwards superintendent of the operating department. This position he left to go with the Northern Contracting Company as superointendent of construction on the hydroelectric development at Tallulah Falls, Ga., for the Georgia Railway & Power Company. Upon the completion of this plant he returned to the Warren-Bisbee Railway to take charge of rebuilding.

OBITUARY

McKendree Hayes Chamberlin, for four years secretary of the Illinois State Railroad & Warehouse Commission, died recently at Los Angeles, Cal. He was a former president of McKendree College at Lebanon, Ill.

J. R. McLain, who was connected with the electrical department of the H. W. Johns-Manville Company, New York, for a number of years, died at the Hahnemann Hospital, New York, on July 28. The remains were removed to Cincinnati, Ohio, for interment.

John Wilkie Harper, superintendent of transportation of the Manhattan & Queens Traction Corporation, Long Island City, N. Y., died on Aug. 1, following an operation. Mr. Harper was born in Scotland forty-two years ago, and had been superintendent of transportation of the Manhattan & Queens Traction Corporation for the last two years. Before that he was with the predecessor company, the South Shore Traction Company. He had previously been in the employ of the Union Railway, the Brooklyn Rapid Transit System, the Metropolitan Street Railway, Kansas City, and in 1906 was with the United Railroads, San Francisco, during the reconstruction after the fire.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Cairo, Pelham & Moultrie Railway, Pelham, Ga.**—Chartered in Georgia to build an interurban railway from Pelham to Moultrie, 50 miles. Capital stock, $75,000. Incorporators: J. J. Hill and D. Turner, Pelham; Mrs. B. H. Polk, Ochlochnee; T. H. Hester and J. T. Forester, Cairo, Ga.; J. M. Mize, J. L. Prince, W. McCord and D. W. Jones, Meigs, Ga.

***Westmoreland (Kan.) Interurban Railroad.**—Incorporated in Kansas to take over the old Kansas, Southern & Gulf Railroad, which extends from Westmoreland to Blaine, a distance of 11 miles. This line will be operated as a gasoline railroad. Capital stock, $40,000. Incorporators: Charles E. Morris, J. W. Arnold and J. N. St. John, Westmoreland; A. C. Wheeler, Garden City; O. C. Collman, Lincoln, Neb.; J. E. Smith and S. E. Smith, Beatrice, Neb.

Casper (Wyo.) Street Railway.—Chartered in Wyoming to build an electric railway in Casper from the Burlington depot to the southern boundary of Casper, via the Butler addition and McKinley Avenue, to connect with a crosstown line which extends from Capitol Hill to the Midwest refinery. It is planned to use storage-battery cars. Capital stock, $100,000. Officers: John Fleming, Casper, president and treasurer; Harley B. Beagle, vice-president and secretary; E. Richard Shipp, general attorney, and Joseph G. Spangler and Charles T. Lynch, directors. [E. R. J., Nov. 29, '13.]

FRANCHISES

***Phoenix, Ariz.**—R. W. Martin, Phoenix, has asked the Council for a franchise to build an electric line on Van Buren Street and thence south on First Avenue to the city limits in Phoenix.

Clovis, Cal.—The Fresno Interurban Railway has received a franchise from the Council along Woodward Avenue and Ninth Street to the Southern Pacific depot in Clovis.

San José, Cal.—The San José Railway has received a franchise from the Board of Supervisors from East San José to Kirk Avenue in San José.

Wilmington, Del.—The Wilmington & Philadelphia Traction Company has received a franchise along the boulevard in Wilmington from Twenty-second Street to Concord Avenue, thence along Concord Avenue to Washington Street and back along Washington Street to Twenty-second Street, completing a loop.

Clearwater, Fla.—C. H. Evans, Clearwater, has received a franchise from the Council to build an electric railway in Clearwater.

Cedar Rapids, Ia.—The Waterloo, Cedar Falls & Northern Railway has received a franchise from the Council in Cedar Rapids. It is also given the right to operate its lines over all the lines now used by the Iowa Railway & Light Company in Cedar Rapids.

Kansas City, Kaw Valley & Western Railway, Bonner Springs, Kan.—Plans are being made by this company to begin work at once on the extension from Bonner Springs to Lawrence.

Boston, Mass.—The Dedham & Medway Street Railway has received permission from the Public Service Commission to extend its railway into the towns of Medway and Franklin and to exercise the franchise rights of the Dedham & Franklin Street Railway and the old Medfield & Medway Street Railway, through Medway and Franklin in connection with a plan to reopen and operate the electric line between these towns. The Dedham & Medway Street Railway has been organized as a successor to the Dedham & Franklin Street Railway. [E. R. J., June 27, '14.]

Springfield, Mass.—The Springfield Street Railway has received a franchise from the Council to extend its line on North Fountain Avenue from the present line of the company on McCreight Avenue at the intersection of McCreight Avenue and North Fountain Avenue to the Home Road in Springfield.

Worcester, Mass.—The Worcester Consolidated Street Railway has asked the Board of Aldermen for permission to relay its tracks in Pleasant Street and also for a relocation of tracks at Grafton Square and in Main Street near Curtis Street in Worcester. The company is asked to consider plans for an extension to include Sixth Street and Mechanic Street, thus making a loop in the east side of Worcester.

Newark, N. J.—The Public Service Railway has asked the Council for franchises to extend its lines in Newark. A new line on Rector Street from Broad Street to Park Place is planned.

Morrisville, N. J.—The Bucks County Interurban Railway, Trenton, has received a franchise from the Council to extend its tracks on Trenton Avenue from the river bridge to Pennsylvania Avenue in Morrisville.

Portland, Ore.—The substitute franchise sought by the Portland & Oregon City Electric Railway has been granted by the City Council in Portland, and after it is advertised for a period of a few weeks it will be acted upon by the Council. The new franchise proposes to allow the company to come into Portland from the south on a considerable portion of East Twenty-fourth Street. Another franchise sought by the same company giving it the right to operate lines through the downtown business section and portions of the central east side, then north to the Columbia River is now pending. Should both franchises be granted a complete system will be in operation competing with the Portland Railway, Light & Power Company.

Avoca, Pa.—The Wilkes-Barre Railway has received a franchise from the Council to extend its tracks through West Avoca to the Lehigh Valley Railroad tracks. Plans are being made to begin work on this extension at once.

TRACK AND ROADWAY

Pine Bluff (Ark.) Company.—Plans are being made by this company to extend the tracks on East Sixth Avenue, from Ohio Street, the present terminus, to Wisconsin Street in Pine Bluff.

Northern Electric Railway, Chico, Cal.—The roadbed between Woodland and Sacramento is being ballasted and the bridges on the entire route will be renewed and strengthened.

Pacific Electric Railway, Los Angeles, Cal.—The line between El Segundo and Los Angeles has been placed in operation by this company.

Visalia (Cal.) Electric Railroad.—Work has been begun by this company on the 3-mile extension from Wood Lake to the base of the foothills in Tulare County.

Denver (Col.) Tramway Company.—Within the next week this company plans to award a contract for the wrecking of a steel viaduct 3000 ft. in length. The viaduct contains about 700 tons of metal. This metal will be sold to the highest bidder within the next thirty or sixty days. The timber stringers and ties will also be disposed of to the highest bidder. The company plans to build a larger new viaduct.

Connecticut Company, New Haven, Conn.—Plans are being considered by this company for a line on Roseland Avenue in Waterbury.

Pekin (Ill.) Street Railway.—The directors of this railway have perfected their organization by the election of the following officers: W. E. Lautz, president; Richard Luick, vice-president; J. M. Rahn, secretary and treasurer. [E. R. J., Aug. 1, '14.]

Augusta & Livermore Street Railway, Augusta, Maine.—No definite plans have yet been decided upon by this company to build its electric railway to connect Augusta, Manchester, Winthrop, Readfield, Mount Vernon, Fayette, Chesterville and Livermore. Charles P. Hatch, Augusta, is interested. [E. R. J., April 12, '14.]

Minnesota Northwestern Electric Railway, Minneapolis, Minn.—Grading has been completed by this company on its line from Thief River Falls to Goodridge, 20 miles, and track has been laid between Thief River Falls and Silverton, 5 miles. Daniel Shaw, Thief River Falls, president. [E. R. J., April 25, '14.]

St. Louis & Western Traction Company, St. Louis, Mo.—Plans have not been definitely decided when construction will be begun by this company for its 40-mile electric line between St. Louis and Gilmore. James D. Houseman, 701 Roe Building, St. Louis, president. [E. R. J., May 24, '13.]

Big Horn Canyon Irrigation & Power Company, Billings, Mont.—Surveys are being made for the storage of water at the reservoir of the Big Horn Canyon. This reservoir will be filled by damming up the water in the mouth of the Canyon. After these surveys are completed, which will be about Sept. 1, 1914, the location surveys for the irrigation feature of the project will be made. Surveys have been completed for the railway location 3 miles east of the mouth of Big Horn Canyon to Custer, via Foster, Hardin and St. Xavier. John J. Harris, Hardin, Mont., president. [E. R. J., May 2, '14.]

Belmont & Northern Traction Company, Lincoln, Neb.—No definite plans have been decided upon by this company as to when construction will be begun on the 3-mile electric railway from Thirteenth Street and P Street in Lincoln to Belmont. [E. R. J., April 12, '13.]

Lincoln (Neb.) Traction Company.—An extension of this line to Thirty-third Street in Lincoln is being contemplated by this company.

Public Service Railway, Newark, N. J.—This company has placed in operation a new crosstown line in the extension of the Kinney line from South Tenth Street and Twelfth Avenue to the Roseville carhouse in East Orange.

Trenton & Mercer County Traction Corporation, Trenton, N. J.—Material is arriving and plans are being made by this company to begin work at once on its 2½-mile extension from Yardville to Crosswicks.

Union Railway, New York, N. Y.—This company has informed the Public Service Commission that the route of the new line from the Bronx across the Willis Avenue bridge will run from the present terminal of the Third Avenue line at Bedford Park, which is also the terminal of the Third Avenue Elevated Railroad, down Third Avenue to its intersection with the Willis Avenue bridge, across the bridge, and westerly on 125th Street, to the Fort Lee Ferry. The new line will issue transfers to all Union Railway lines and the lines of the New York City Interborough Railway Company.

Frontier Electric Railway, Niagara Falls, N. Y.—Right-of-way has been obtained, with the exception of a short distance, and construction will be begun in the fall by this company on its line to connect Niagara Falls, Buffalo, Tonawanda and North Tonawanda. James S. Simmons, Niagara Falls, general manager. [E. R. J., June 13, '14.]

Hiawassee Valley Railway, Andrews, N. C.—Work has been begun by this company on the construction of its 25-mile line between Andrews and Hayesville. S. E. Cover, Andrews, president. [E. R. J., Feb. 28, '14.]

Atlantic & Carolina Railroad, Kenansville, N. C.—The 10-mile line between Kenansville and Warsaw has been completed by this company and will soon be placed in operation. H. D. Williams, Kenansville, N. C., is interested. [E. R. J., May 2, '14.]

Waynesville & Canton Electric Railway, Waynesville, N. C.—On account of inability to secure financial backing this company has abandoned the project to build the 12-mile electric railway to connect Hazelwood and Canton, via White Sulphur Springs, Clyde and Lake Junaluska. Henry T. Sharp, Asheville, promoter. [E. R. J., Jan. 3, '13.]

Wilmington-Carolina Beach Railway, Wilmington, N. C.—This company, which plans to build an electric railway between Wilmington and Carolina Beaches, has organized and elected the following officers: C. C. Chadbourn, Wilmington, president; A. E. Leckie, Washington, D. C., vice-president; Joseph L. Loughlin, secretary and treasurer, and Hall Davis, Petersburg, Va., general counsel. [E. R. J., July 4, '14.]

Wilmington & Fort Fisher Railway, Wilmington, N. C.—Preliminary arrangements are being made by this company for its 18-mile electric railway between Wilmington and Fort Fisher Sea Beach. L. Kure, Wilmington, secretary. [E. R. J., July 25, '14.]

Cleveland (Ohio) Railway.—The 1-mile extension of the St. Clair Avenue line from London Road to Dille Road, in Cleveland, has been placed in operation by the company.

Morrisburg & Ottawa Electric Railway, Ottawa, Ont.—The contract for the construction of this railway has been awarded and plans are being made to begin work at once. Further details concerning the contract will be given out later. This 47-mile railway will connect Ottawa and Morrisburg. J. G. Kilt, Citizens' Building, Ottawa, president. [E. R. J., July 11, '14.]

Baker, Ore.—Promotors for an electric line between Baker and Richland with a local line in Baker with a branch from South Baker to the depot and possibly one or two other lines, tapping the east and north side of Baker, have been busy in Baker and the Eagle Valley during the past month. Joseph Kreis, Portland, is promoting the project, and according to his statements sufficient capital is back of him to build the proposed lines. Citizens of Baker and farmers in Eagle Valley have signified their willingness to assist in every way possible in the construction of the project.

Puget Sound & Willapa Harbor Railway, Portland, Ore.—This company has begun the work of laying tracks in Chehalis.

Hershey (Pa.) Transit Company.—Work has been begun by this company on the Elizabethtown & Deodate extension, from Hershey to Elizabethtown.

Monongahela, Ellsworth & Washington Railway, Washington, Pa.—This company has received an extension of time from the Public Service Commission in which to place in operation its line in Monongahela City. This line will connect Monongahela and Washington, via Pigeon Creek, Bentleyville and Ellsworth. James Bryant, Pittsburgh, engineer. [E. R. J., Jan. 10, '13.]

Williamsport (Pa.) Passenger Railway.—This company is asked to consider plans for an extension along the route of West Third Street to Newberry.

Rhode Island Company, Providence, R. I.—Work has been begun by this company on Broad Street, Pawtucket, laying new rails and crossovers preparatory to the elimination of all railroad crossings at grade and relocation of the roadbed and station of the New York, New Haven & Hartford Railroad at the Pawtucket-Central Falls division line.

***Prince Albert, Sask.**—A by-law to raise $250,000 to build an electric railway in Prince Albert is to be submitted to ratepayers.

***Brenham, Tex.**—Plans are being considered to build interurban lines extending out from Brenham to half a dozen different directions, making Brenham the center for the entire system. The various points of the proposed circle include Independence, William Penn, Washington, Chappell Hill, Phillipsburg, Millersville and Gay Hill. Frank Eberle, Brenham, of the Young Men's Business Association, is interested.

Dallas, Tex.—Preliminary arrangements are being made by the Southern Methodist University to build an electric railway from the University to the terminus of the Dallas Consolidated Electric Railway. Myers & Noyes, 403 Juanita Building, Dallas, are the engineers.

***Dallas, Tex.**—A local company has been formed in Dallas for the purpose of building a 95-mile electric railway from Dallas to Paris. It is understood that the route of the line will follow the Gulf, Colorado & Santa Fé Railroad, passing through Carland, Wylie, Celeste, Wolfe City, Ladonia and intermediate points. Details of the project have not yet been announced, but it is known that many leading business men of Dallas are back of the project.

Southern Traction Company, Dallas, Tex.—An extension of the East Waco Street line to Bellmead, 1½ miles, is being contemplated by this company.

Fort Worth & Denton Interurban Railway, Fort Worth, Tex.—In order that condemnation proceedings might be started by the Tarrant County Traction Company on the few miles of the right-of-way of the Fort Worth-Denton Interurban line not yet secured, the Fort Worth-Denton Interurban Railway, organized here to build that line, was formally dissolved at a recent meeting of the stockholders. The company turns over to the Tarrant County Traction Company the right-of-way so far secured and a $75,000 bonus and also guarantees a franchise at Denton. Stockholders from Denton who were present at the meeting announced that that city will grant as liberal a franchise to the new company as its charter will allow. E. E. Baldridge, president of the old company, will go to Denton to look after the franchise proposition. It is expected that construction will be begun as soon as all of the right-of-way deeds are filed and the franchise is obtained at Denton. [E. R. J., July 18, '14.]

San Antonio & Austin Interurban Railway, San Antonio, Tex.—Financial arrangements are being completed by this company and plans are being made to begin the construction of this 27-mile electric railway to connect Austin, San Antonio and New Braunfels in the near future. W. B. Tuttle, San Antonio, vice-president. [E. R. J., May 9, '14.]

Ogden (Utah) Rapid Transit Company.—This company has awarded a contract to the Ohio Brass Company, Salt Lake City, for the material for the electrification of the extension north from Brigham City to Preston, Idaho.

Salt Lake & Utah Railroad, Salt Lake City, Utah.—This company has placed in operation its 48½-mile railway between Salt Lake City and Provo. It is planned to extend this line from Provo south to Payson, 20 miles in the near future. W. C. Orem, Salt Lake City, president.

Blaine-Lynden Electric Railway, Blaine, Wash.—Announcement was recently made that practically all of the right-of-way for this railway has been secured and that the construction of the line will begin at once. The City Council here has already granted the company a franchise in Blaine and a similar franchise has passed first reading before the Council at Lynden. The line when completed will pass through 14 miles in northwest Washington and will join with the Great Northern Railway at Lynden, thus greatly increasing the shipping facilities in this section. An anthority asserts that before this line is completed a second line will be started, extending from Bellingham to Blaine via Lynden. [E. R. J., June 6, '14.]

Everett Railway, Light & Water Company, Everett, Wash.—It is reported that the Stone & Webster Corporation, which operates this railway, will extend the electric line in Everett from the depot to the main part of the town. Two routes are under contemplation, either of which can be easily secured.

Seattle (Wash.) Municipal Railway.—A tentative routing for the Ballard division of the municipal railway in Seattle was outlined recently by the City Utilities Committee contingent upon the purchase or gift to the city of the Loyal Heights Street Railway. Negotiations for that line will be opened immediately. The route as planned by Councilman Erickson leads from the northern extremity of Division A at Third Avenue west and Nickerson Street over the new Fifteenth Avenue northwest bridge into Ballard. Thence the line will proceed up Leary Street to Market and over Market to Sixty-fifth Street where connections will be made with the Loyal Heights line in Seattle.

Appalachian Power Company, Bluefield, W. Va.—Grading has been completed and tracks are being laid by this company on its South Bluefield extension in Bluefield, from Golf Street to the Bluefield-Graham fair grounds.

Parkersburg, Maretta & Interurban Railway, Parkersburg, W. Va.—Plans are being made by this company for an extension on Second Street in Parkersburg.

West Virginia Traction & Electric Company, Wheeling, W. Va.—Plans are being considered by this company to double-track its line in the western section of Fulton on the National Road and Bow Street.

SHOPS AND BUILDINGS

Illinois Traction System, Peoria, Ill.—The foundations of the station and office building at Hamilton and Jefferson Streets, Peoria, are now finished and a permit for the superstructure will be issued soon. The contract for the steel work has been let to the Decatur Bridge Company, Decatur, Ill., and other contracts will be awarded from time to time. The building will cost $400,000 and the general construction permit will approximate $300,000. The main building will be seven stories in height, fronting 72 ft. on Jefferson Street and extending about 100 ft. on Hamilton Street. Back of this seven-story structure will be a two-story building to the alley. Parallel to the 72-ft. front office building there will be a five-track terminal train shed of ornamental construction, also fronting on Jefferson Street.

Butte (Mont.) Electric Railway.—During the next two weeks this company will award contracts to build a new carhouse in Butte. The structure will be 46 ft. x 200 ft. and of concrete foundation, pit walls and wooden superstructure. It will contain four tracks.

Cleveland (Ohio) Railway.—A contract has been awarded by this company to the William I. Thompson Company for the construction of the new Superior Avenue carhouses at Superior Avenue and 103d Street in Cleveland. The group of new buildings, four in number, according to the contract, will cost approximately $150,000. The buildings are to be completed by Jan. 1, 1915, when the present carhouse at Superior Avenue and East 105th Street will be abandoned and the property sold. The first group of buildings forming the Harvard Avenue carhouses at Harvard Avenue and East Forty-ninth Street will be ready for occupancy Sept. 1.

Toledo, Bowling Green & Southern Traction Company, Findlay, Ohio.—This company is now building a new freight house at Toledo. The structure is 50 ft. x 160 ft. and of brick, steel and concrete construction and will have three tracks for loading and unloading.

Hull (Que.) Electric Railway.—Plans are being made by this company to award the contract soon to build a 60-ft. tower with a capacity of 20,000 gallons at its carhouse at Deschenes.

POWER HOUSES AND SUBSTATIONS

Illinois Traction System, Champaign, Ill.—This company will soon construct a new high tension transmission line from its power house in the north part of Champaign, through the extreme northern parts of both Champaign and Urbana, joining its present line at a point about 2 miles east of Urbana. The new line will be about 5 miles long.

Southern Iowa Railway & Light Company, Albia, Ia.—This company has recently placed an order with the Westinghouse Electric & Manufacturing Company for one 200-kw, 600-volt, three-phase, sixty-cycle, 1200 r.p.m. rotary; one 150-kw motor generator set consisting of one 150-kw, 125/250-volt, three-wire, 900-r.p.m. generator and one 182-kva, 2200-volt, three-phase, sixty-cycle, 100 per cent P. F. motor; three 75-kva, single-phase, sixty-cycle, 2200-volt high tension rotary voltage low tension type SK transformers; one eleven-panel switchboard; two three-phase, 2200-volt, two-phase, 2200-volt auto transformers; two 17-kw regulators; 186 street hoods; fifty brackets; nineteen arc lamps, and nineteen auto current transformers.

Winnipeg, Selkirk & Lake Winnipeg Railway, Winnipeg, Man.—Plans are being made by this company to build a new substation at Stoney Mountain.

Toledo, Bowling Green & Southern Traction Company, Findlay, Ohio.—This company is now building a new coal-crushing device at its power house in Findlay.

Lebanon & Ephrata Railway, Lebanon, Pa.—This company has ordered two 300-kw, 600-volt, six-phase, twenty-five-cycle, 750 r.p.m. commutation pole rotary converters and two three-panel switchboards to control same; two 250-kva transformers O. I. S. C. outdoor type, three-phase, twenty-five-cycle, 11,000-volt high tension rotary voltage low tension. One complete portable substation car including 300-kw, 600-volt, six-phase, twenty-five-cycle, 750 r.p.m. rotary converters. One 250-kva, three-phase, twenty-five-cycle, 11,000-volt high tension O. I. S. C. outdoor type transformer, and necessary switching equipment. This apparatus was ordered from the Westinghouse Electric & Manufacturing Company.

Chattanooga Railway & Light Company, Chattanooga, Tenn.—This company has been awarded a five-year contract for all the city lighting in Chattanooga. The present annual income from the contract will approximate $28,109. The city maintains 823 lamps as against 585 three years ago.

Jackson Railway & Light Company, Jackson, Tenn.—During the next few weeks this company plans to purchase shaker grates for four boilers, and also a 250-kw rotary converter for its power house in Jackson.

Manufactures and Supplies

ROLLING STOCK

Cleveland (Ohio) Railway has ordered 100 center-entrance motor cars from the G. C. Kuhlman Car Company.

Albany Southern Railroad, Albany, N. Y., has been authorized by the Public Service Commission of the Second District of New York to purchase an express car to be equipped with auxiliary snow fighting equipment.

New York Municipal Railway Corporation, Brooklyn (N. Y.) Rapid Transit System has been authorized by the Public Service Commission of the First District of New York to order 100 additional new steel cars, for operation in the subways that will go to that company under the dual system agreements. Some time ago the company ordered 100 cars, and these will be delivered in December. The second order will be placed very soon, and the delivery of the cars will take place in the spring or summer of next year.

TRADE NOTES

Sidney G. Johnson has been elected a vice-president and director of the General Railway Signal Company, Rochester, N. Y., with headquarters at 55 Liberty St., New York City.

M. H. Loughridge, formerly on the engineering staff of the Union Switch & Signal Company and the New York, Westchester & Boston Railway, has recently been appointed office engineer in the New York office of the Federal Signal Company.

Street Railway Signal Company, Inc., Philadelphia, Pa., has been awarded the contract for the signals which are to be installed by the New York & Queens County Traction Company on its Jamaica Division in accordance with the order issued by the Public Service Commission of the First District of New York. The work of installing the signals must be completed by Oct. 1.

Lagonda Manufacturing Company, Springfield, Ohio, is building a new addition to its factory in order to accommodate its increased business and increase its facilities for specialty manufacturing. Its present factory will be given over entirely to the manufacture of tube cleaners and specialties and the new addition will be equipped for handling the larger and heavier class of work, such as automatic cut-off valves and multiple water strainers, the castings of which run into very large sizes.

H. W. Johns-Manville Company, New York, N. Y., has announced that Frank E. Brown has become associated with the company, and will act as a special representative, devoting his attention to the further sales development of "Noark" service meter protective devices. Mr. Brown was electrical engineer for the department of water supply, gas and electricity of New York City from 1889 to 1909 and was prominent in creating the demand for and in urging the adoption of meter protective devices among the lighting companies of the country.

Federal Signal Company, New York, N. Y., reports that the Public Service Commission, New York, First District, has approved the acceptance of the Federal Signal Company's proposal for the installation of an alternating-current automatic block-signal system on the Centre Street Loop. This is part of the first section of the new subway system to be put in operation. The contract is for 2.1 miles of double-track automatic block signaling and three interlockings including automatic stops. As direct current is used for propulsion, alternating-current track circuits and apparatus of the Federal Signal Company's design and manufacture will be used throughout.

Electric Service Supplies Company, Philadelphia, Pa., has sold 200 Keystone car signs to the New Orleans Railway & Light Company, New Orleans, La., for installation on its new cars. Other recent orders for Keystone signs have been received from the Altoona & Logan Valley Electric Railway and the Wilkes-Barre Railway. The Electric Service Supplies Company has also recently sold the Reading Transit & Light Company complete equipments of Keystone motorman's seats for its interurban cars. The Keystone motorman's seats are permanently attached to the car. They are adjustable in height and may be instantly collapsed so that they will be entirely out of the way when not in use.

William R. Garton has been appointed sales manager and associate engineer of the Protective Signal Manufacturing Company, Denver, Col., and hereafter the main sales office of this company will be under Mr. Garton's direction at 299 Broadway, New York. The Protective Signal Manufacturing Company manufactures a complete line of highway crossing alarms, which are in use on a number of steam and electric lines in the East and West. The company's chief product is a circuit opening and closing device of the oscillator type, which clamps to the base of the rail and against the web and is operated by the movement of the rail due to the passage of trains. It also makes crossing bells of several types, automatic relays and automatic cut-outs for highway crossing alarms and a complete line of battery boxes and masts provided with signs, illuminated or non-illuminated, and with or without audible signals.

Theodore W. Siemon has been elected secretary and treasurer and a member of the board of directors of the Union Switch & Signal Company, Pittsburgh, Pa., succeeding James H. Johnston, retired. Mr. Siemon was born and educated in Pittsburgh. He began his business career in 1877 with Lewis, Oliver & Phillips, now the Oliver Iron & Steel Company. In 1887 he accepted a position with the Philadelphia Natural Gas Company as assistant to the secretary, who also had charge of the distribution and selling of the company's product. In 1893 he was placed in charge of the business of the Allegheny Heating Company, a subsidiary of the Philadelphia Company, as assistant treasurer. Two years later he was elected treasurer of the Philadelphia Company. From that position he was promoted to the office of general manager. When Mr. Westinghouse disposed of his interests in the Philadelphia Company in 1899 Mr. Siemon was elected assistant treasurer of the Westinghouse Electric & Manufacturing Company, with headquarters in New York. He succeeded to the treasurership in 1906. During 1907 and 1908 he was also a director in the company. He has been a director in the Bryant Electric Company and the Perkins Electric Switch Manufacturing Company since 1906.

Union Switch & Signal Company, Pittsburgh, Pa., announces the following change in its organization: W. H. Cadwallader, general manager, Swissvale, Pa.; J. S. Hobson, acting general manager, Swissvale, Pa.; C. E. Denney, assistant general sales manager, Swissvale, Pa. Mr. Cadwallader, the new manager, was born in Pittsburgh in 1876. In 1901 he entered the employ of the Union Switch & Signal Company as blue-printer. In February, 1892, he was made messenger in the office of the superintendent of works, later on becoming clerk in the same office and in the general manager's office. In 1901 Mr. Cadwallader was put in charge of the specification department. Later he had charge of the estimating department, and in 1912 he was made assistant general manager, from which position he was promoted to the general managership. Mr. Hobson entered railroad service as engineer apprentice in the shops of the Great Southern & Western Railway of Ireland in 1884. In 1889 he entered the employ of the Chicago, Burlington & Quincy Railway. In January, 1892, he became construction foreman for the Union Switch & Signal Company in the Chicago district, and in 1895 was appointed supervisor of electric signals for the Michigan Central at Detroit. When the position of signal engineer was created by the Santa Fe in 1897 Mr. Hobson was chosen to fill it and he remained in the position until he re-entered the service of the Union Switch & Signal Company in January, 1901, as assistant engineer. Later he became assistant general manager and western manager. The company has contracted with the Indianapolis, Columbus & Southern Traction Company to install a.c. automatic block signals operated by the T.D.B. system, which will permit two trains to follow each other between sidings, but prevent opposing movements. The total distance signaled will be 23.1 miles, and this will be protected by thirteen blocks, controlling 26 Style "B" one-arm semaphore signals, and 26 model "13" electric light signals. Galvanometer relays will be used on the track circuits, and vane relays on the line circuits. The company has also contracted with the Illinois Traction System to install Saxby & Farmer mechanical interlocking plants at four points in Illinois. One of these plants is north of Staunton, where the Illinois Traction System crosses the Wabash, one at Benld, where the Northwestern is crossed, one east of Mt. Olive at the crossing with a spur of the Wabash, and the fourth plant is in Staunton, at another crossing with the Wabash. The signals are mechanically operated and there are no distant signals for the signals covered by the interlocking plant. The signals on the Illinois Traction System stand normally clear, and the plant is equipped with a time lock. The switches and derails are operated by switch and lock movements. Another T.D.B. installation of automatic block signals is being completed on the Cleveland, Southwestern & Columbus Railway near Cleveland, Ohio.

ADVERTISING LITERATURE

Ohmer Fare Register Company, Dayton, Ohio, has issued a circular on fare boxes in which it has summarized the apparent advantages of fare boxes and the general objections to such boxes and has described and illustrated its own safe deposit box.

W. S. Barstow & Company, Inc., New York, N. Y., recently published a thirty-five-page, leather-bound book, giving in convenient form general data regarding public utilities companies under its management. Each company is discussed individually in relation to its geographical location, its intercorporate relations, its capitalization, earnings and expenses for the last fiscal year, franchises, population served and other matters affecting its corporate life. There is also a map showing the exact location and extension of properties of each company. Of the forty-seven companies covered by the book, twenty-nine are electric railways. The company announced that reports of engineers and accountants for the various companies are on file at the main office and that any statistics regarding the individual companies not presented in the book will be furnished to the holders of securities of the companies upon application.

Galena Signal Oil Company, Franklin, Pa., has reprinted in pamphlet form its answer to the quotation in the brief of Louis D. Brandeis, special counsel for the Interstate Commerce Commission, in the rate increase case, in which he referred to economies in the use of oil for lubrication said to have been effected in Panama. In conclusion the company says: "If comparative estimates were made by qualified experts as to the costs per unit of work performed by the railroads, it would be found that the railroads in the United States are lubricating their equipment much cheaper than this service is performed on the isthmus. The inference is that low-priced oils and the supervision given on the isthmus are set up as standards, whereas railroads in the United States have been following this practice of supervision for many years, and if a fair comparison were made with accurate statistics, considering character of service and comparative units of work performed, it would be demonstrated that the railroads in the United States are lubricating at a cost much less than is obtained on the isthmus."

NEW PUBLICATION

Corporate Promotions and Reorganizations. By Arthur S. Dewing. Harvard University Press, Cambridge, Mass. Cloth bound, 615 pages, $2.50.

This book, which is a study of the financial policy of certain individual corporations which at one time or another have found it necessary to undergo a reorganization of their capitalization, is a scholarly contribution to the literature of trusts and corporation finance. The major portion of the book is devoted to a detailed study of a selected group of industrial corporations, each of which has passed through the cycle of promotion, failure and reorganization. The consolidations discussed are: the United States Leather Company, the starch consolidations, the glucose combinations, the National Cordage Company, the Westinghouse Electric & Manufacturing Company, the National Salt Company, the United States Realty & Construction Company, the American Bicycle Company, the American Malting Company, the New England Cotton Yarn Company, the cotton duck consolidation, the asphalt consolidation, the United States Shipbuilding Company and the American Glue Company. The cases chosen, while not exhaustive, serve to illustrate best all phases of corporate history in a comparatively brief period. The book abounds in notes and tabulated data that give complete information on the smallest auxiliary points.

The chapter devoted to the analysis of the history of the Westinghouse Electric & Manufacturing Company is probably of greatest interest to the electric railway field. The author gives the best exposition of the financial successes and difficulties of the Westinghouse Company that has ever appeared. As Mr. Dewing states, the history of the Westinghouse Electric & Manufacturing Company is a record of marked achievement in the application of scientific knowledge to practical uses. To the mind of the author, both the strength and the weakness of the Westinghouse Company lie in the inventive genius of its founder. The company has always been strong from the side of technical achievement, but weak from the side of the administration of its finances and its control over the avenues of capital and investment. The main cause for the two reorganizations of the company was the fact that the owners failed to note that a business of large magnitude, even though its credit be excellent, must be fortified by considerable reserves in the form of fluid assets not affected by the ordinary fluctuations in the demand and supply of money. The author notes that the methods used to secure relief in each of the company's reorganizations were identical. In neither instance was the reorganization accomplished through the judicial loss of the property, or was there an exchange of entirely new securities for old, or a new funded debt created. The positive expedients were the same—the merchandise creditors and bankers funded their debt into stock, and new stock in suitable amounts was issued at par. In regard to the future, the author closes with words of optimism.

The last chapters of the book are devoted to a summary of the promotion of consolidations that have undergone reorganizations, of the conditions and causes leading to reorganization and of reorganization expedients. Mr. Dewing states that the link between the promotion of a corporation and its subsequent failure and reorganization often lies in the early management, and in cases where early interests have been willing to forego immediate profits and conserve the funds, the enterprises have been placed on a sound footing. The same problem of conservatism of management presents itself in the period immediately before reorganization in connection with the payment of unearned interest or unearned dividends. In summarizing the reorganization expedients discussed in the book, Mr. Dewing states that most reorganizations have sought to relieve accumulated and unmanageable floating debt brought about by the deflection of money from the needs of the business to the payment of interest and dividend charges. All plans of reorganization have sought to improve the company's position so that the amounts required for interest payments should be within the minimum earnings of the corporation, and the preferred stock dividend records no longer a hopeless burden upon the future credit of the reorganized company.

The *laissez-faire* point of view of the author throughout the book is worthy of notice. He states that he has been impressed in his study of corporate promotions and reorganizations by the powerlessness of mere aggregates of capital to hold monopoly and also by the tremendous importance of innate individual ability or its lack in determining the success or failure of any enterprise. With these observations in mind, the author hazards the belief that whatever trust problems exist will work out their own solution. Legislative regulation is liable to perpetuate the unfortunate corporation by furnishing an artificial prop to support natural weaknesses. It is on this point that other men may take issue with the conclusions of the author.

While unfortunate management and vigorous competition may have worked out the disintegration of some trusts, in the case of combinations having a wide monopoly of raw material or patent rights and possessed of enormous capital, these forces may work out too slowly to make a passive policy of dealing with them advisable.

Electric Railway Journal

Vol. XLIV NEW YORK, SATURDAY, AUGUST 15, 1914 No. 7

FINING RAILROAD TRESPASSERS IN ILLINOIS

The move to arrest and fine all trespassers on Illinois railroad property, recently made by the Public Utilities Commission of Illinois with the consent of Governor Dunne, cannot be commended too highly. To this end municipal and railroad authorities have been instructed to arrest all trespassers. While railroads, both steam and electric, have taken every possible precaution to reduce the number of trespassers to a minimum, they have not been aided by the state or local authorities. Accordingly, this move is of great importance to them, and it is to be hoped that it is merely the beginning of a national campaign. When it is considered that more than one-half of the people killed by railroads in the United States are trespassers, it should be cause enough to make trespassing not only illegal but subject to fine. The fact that these trespassers illegally were on dangerous ground did not serve as sufficient notice to keep them from using railroad right-of-way as public thoroughfare. On the other hand, railway companies are being forced to take every precaution to protect their passengers, hence it seems right and proper that the public should be forced to protect itself in this matter.

DISCUSSIONS ON THE WAR

One of the companies in a large city has given instructions to its trainmen to refrain from discussion of the war. The very good reason stated by the management is that as this is a nation with many elements of foreign birth or descent in its citizenship, disputes may arise easily from casual remarks and the final result might be an outbreak of some nature. The motive behind the order is the same that has led to the discouragement of public gatherings in a large city by adherents of one side or the other. If neutrality is to be preserved successfully, the responsibility for this safe policy will lie not only in the executive officials of the government but also in the rank and file of the population. It is plain that if the confidence which both factions in Europe now appear to have is succeeded, as is likely to be the case soon, by a realization that the cause of one is desperate, there may be an effort, both from Europe and from sympathizers in this country, to drag this nation into the conflict. Neutrality is easy to preserve under the present conditions, but it may be less easy if pressure should be directed against this country. It is hard to restrain trainmen from expressing their feelings, but in observing the strict neutrality which should prevail, it is desirable that the dangers of the contrary course be appreciated. Trainmen are in close contact with the public at all times and will be provoked or tempted to reply to sallies. Later, when bitterness succeeds the first sentiments of surprise and horror inspired by the war, it will be still harder to keep from talking. Whether or not companies issue strict orders to their men in this matter, they will improve their own position with the public by discouraging argument with passengers.

EXPORT TRADE DURING WAR

The present European war should eventually redound appreciably to the benefit of American manufacturers. The countries now involved in war have in general been our smallest patrons of electrical apparatus, owing chiefly to the operation of protective tariffs. The exception to this is England, where American manufacturers have been compelled to meet the competition of German exports. On the other hand, Canada, Japan, Mexico, South America, South Africa, East Indies and China have all been good customers, and we still have access to their markets. If the English admiralty plans result in keeping the high seas clear for English shipping, our manufacturers will probably do a fairly large export trade with that country, for supplies from Germany will be held back by blockade. There are some latent possibilities in Italy also, provided the Italians succeed in maintaining their condition of neutrality in Europe. The export trade in strictly electrical goods from America has reached a height of more than $25,000,000 a year. During the last year or two a slight tendency toward a decline has been in evidence, but exporters have generally looked upon this as a sympathetic reduction caused by a general falling off in the volume of world trade. The present closing of the purchasing markets of Europe affects so small a percentage of our total export trade in electrical appliances that it can easily be omitted from calculations. On the other hand, in the opinions of those who have studied the subject, the electrical export trade of America, which last year reached a total of about $25,000,000 should greatly increase during the next twelve months.

PROBLEMS TO BE SOLVED

Before the present opportunity for increasing our electrical export trade can be fully grasped, there are certain problems that must be more fully solved, such as that of packing goods for foreign shipment and that of establishing better credit relations abroad. The safe packing of goods has been a particularly persistent and annoying problem of American shippers in connection with South American trade, but this should not be a difficulty that would long baffle American ingenuity. Much emphasis also has always been placed upon the advantages enjoyed by our European competitors, especially in South America, by virtue of their longer credits. During the last few years, however, European and American manufacturers have been brought much closer together in the matter of credits. The Germans have displayed a tendency toward a retrenchment from a previous rather excessively liberal policy regarding credits, and American merchants have shown an appreciable relaxation from their former rigid cash policy. Our principal commercial agencies have established branches or chains of correspondents throughout South America, and some of our largest banks have developed their own foreign credit departments. It must be admitted that the average merchant has not yet been clearly educated up to using our existing South American credit system and European manufacturers still have the advantage of service by branches of important home banking institutions. Nevertheless, the progress that has already been made in South America in the face of competition, seems to us an auspicious sign of the complete development that should now take place in the face of the present restricted competitive market.

THE SPECIFIC VERSUS THE GENERAL

A most striking contrast exists between the majority report regarding the Crosser bill for the government ownership of electric railways in the District of Columbia, abstracted in the ELECTRIC RAILWAY JOURNAL of July 4, and the report recently submitted by the minority members of the District committee. Whereas the bulk of the majority report (thirty out of thirty-five pages, to be exact) was devoted to a general exploitation of economic theories regarding public ownership and only 2 in. to an unsupported conclusion of seven points concerning the District railways, the minority report confines itself specifically to the proposed bill, its faulty construction and the advantages claimed by its proponents. The majority report is at best an incomplete and unauthoritative discourse on the general principle of government ownership, while the minority report is a complete analysis of the proposal, good or bad, as it relates to the matter actually under consideration. In other words, it deals with the facts. This difference is worthy of note as being characteristic of two modes of thought—the loose and the analytical.

The first part of the minority report deals with several aspects of the faulty construction of the Crosser bill. The point covering the obligation of the city to take over the railways at an award to be made by the Public Service Commission, whether excessive or not, is particularly interesting in view of the fact that out of the total fifteen witnesses in favor of the bill only four discussed the question of cost. As pointed out, it is impossible at present to ascertain what a condemnation award would amount to, but the minority members are quite correct in their assertion that in the light of current decisions the supporters of the bill have no reason for expecting the award to be limited to a bare physical value, exclusive of going concern allowances. Moreover, it is pointed out that the street railways operating within the District of Columbia extend beyond the limits of the District into a territory over which the federal government has no jurisdiction. The commission is empowered to condemn the outlying lines, but no intelligent method has been suggested for so doing and no indication made of the cost that would result.

The loose construction of the entire bill is also exemplified by Section 9 and Section 10. The first of these provides for the operation of the condemned railways under rules not in conflict with existing acts of Congress. Whether the railways would thus become amenable to all existing laws pertaining to the District is a matter of conjecture, but the efficient electric railway manager would not desire even to admit the possibility of employees receiving thirty days' leave with pay annually and thirty days' sick leave annually, and that purchases over $25 in amount should be placed in federal government hands. Section 9 authorizes the appropriation of $50,000 out of the District funds for the expenses of the condemnation proceedings, an appropriation which is not to be reimbursed out of the sale of bonds and which, in the light of the $1,000,000 paid by the City of Holyoke, Mass., for condemnation proceedings to acquire its gas and electric plants, is palpably absurd. It does not require much discernment to see in this very section the entering wedge for a continual chopping into the District funds for money to run the railways under government ownership.

The second main division of the report is devoted to a general refutation of the local advantages of government ownership so nonchalantly asserted by the majority section of the committee. To use the latter's own words: "The experience of the British Isles with city operation of street car lines shows what may be reasonably expected to be the experience here." We had supposed that every schoolboy recognized the worthlessness of the device of analogy as a means of proof except in cases where absolute similarity of structure, education or environment could be shown. Why this fundamental principle of argumentation should be so slighted by representatives in our national halls of debate is certainly not comprehensible. As we have often stated in these columns, the political conditions and ideals in Great Britain and Germany do not obtain in this country, and with all the assumptions one may care to make regarding these countries, no valid argument may be derived in support of the trial of the proposition here.

We are not compelled to be content with such a general rebuttal of the contention of the committee majority, however, for the minority group has taken up one by one and, as far as is possible in a few words, punctured the advantages of municipal ownership for

Washington claimed by the advocates of the bill. Neither in public nor in private operation can there be found any reason for asserting that municipal ownership in Washington would result in a great reduction of fares, or a large increase in wages to correspond to the San Francisco Municipal Railway wages. Even if the railways were bought at the absurdly low $25,000,000 valuation of the parent of the bill and the burden of taxes were dodged by shifting it to the other taxpayers of the District, the granting of the wage increase which has been dangled in the report would mean an annual deficit of more than $250,000, and fare reductions would make the financial disaster still greater. If the railways were bought at any price tending to equal the present market value of the securities, a deficit would be quite possible without either reduction in fares or increase in wages. In regard to improved service and extensions of lines, the minority report pertinently points out that no admissible testimony was offered at the hearing in regard to complaints along these lines. If these or other conditions, such as those of labor and publicity, are now unjust, as the minority members do not believe, then the Public Service Commission should be required to carry out the functions for which it was created.

It is said that universal transfers are desired in Washington. The minority members of the committee frankly say that the city is entitled to this improvement at the earliest possible moment, but they also point out that the Public Service Commission has ample authority to compel free transfers if the railways can afford them. If the excessive cost of such service can be proved, however, it is obvious that universal transfers under municipal ownership would be established only at the expense of other service and at the sacrifice of needed income. If the District of Columbia commissioners realized more deeply their important position as impartial arbitrators between the utilities and the public, as did the New York commissioners in the recent Brooklyn transfer case, they might take some steps to find out the financial possibility of a universal transfer system instead of spending their time in blind advocation of the theory of municipal ownership.

It would be impossible to leave the minority report without referring to the light it throws upon the state of public sentiment in Washington regarding the proposed bill. It may be recalled that one of the witnesses, as previously mentioned in the ELECTRIC RAILWAY JOURNAL, stated that the people of Washington were "overwhelmingly" in favor of the bill, but that during a four-hour session, even though assisted by a city directory, he could name only sixteen people who favored government ownership, four of these being the three public service commissioners and the corporation counsel. Just as entertaining as the above incident is the fact that after repeated invitations, public notices of meetings and prolonged meetings, only fifteen of the 350,000 citizens were interested enough to testify in favor of the bill, and of these fifteen only four were taxpayers, and these four represented a property valuation of only $23,197 out of the total of $380,000,000.

STEEL SHEATHING FOR CAR SIDING

A surprising diversity of opinion exists in regard to the most desirable thickness for the sheet steel that is now so generally used for the side sheathing between the sills and belt rails of electric railway cars. In the case of the semi-steel car, the sheathing on each side acts as a girder supported on the body bolsters to carry the weight of the car body without the aid of side or center sills. The girder has to be reinforced by the belt rail along its upper edge, as the inherent stiffness of such a member is a feature of importance. This may account for the fact that with cars of side-girder construction a thickness of side sheathing of ⅛ in. is widely used, although many cars of this type, notably those of the Chicago Railways and the Pittsburgh Railways, have a side-sheathing thickness of 3/32 in. However, in the case of all-steel cars, side sheathing of ⅛-in., 3/32-in., and 1/16-in. plate seems to be used indiscriminately.

The use of ⅛-in. plate for side sheathing undoubtedly originated from a belief that this was a minimum workable thickness, and that in city service safety against collisions with the poles or wheel hubs of vehicles demanded more resisting power than was supplied by very thin sheets of steel. However, that the use of even 1/16-in. side sheathing is permissible is demonstrated by the stepless cars of the New York Railways. These cars are now being operated upon Broadway in New York City, where the traffic is exceptionally congested, and notwithstanding the very low sides necessitated by the stepless design no difficulty on account of puncturing the 1/16-in. side sheathing has been experienced.

In these cars, of course, the side sheathing does not act as a girder in the commonly accepted meaning of the term. Instead, the entire car side acts as a truss, of which the belt rail is the compression member, and the side sill, which is composed of a 3-in. angle, acts as the tension member. Therefore the side sheathing, when it enters into the truss action of the side at all, is in tension throughout its entire width. No doubt the sheathing, in this case, acts as a gusset plate to hold the posts and belt rail square, but in general the difficulty of riveting such a thin sheet obviously limits its action except for short distances away from the stiffening members.

Certainly the successful operation of the New York cars upon one of the most congested thoroughfares in the country disposes of the argument, so generally heard in favor of ⅛-in. sheathing, that a thinner sheet will not afford the required protection against vehicles. As a corollary, the argument that strains need not be carried up to the letter board or plate also fails, and with it disappears the only logical reason for the popularity of the side-girder construction as opposed to one of all steel. However, even where the side-girder construction is retained there seems to be no longer any good cause for carrying 250 lb. of extra weight in two girder plates that are ⅛-in. thick when it has been so thoroughly demonstrated that 3/32-in. plates will satisfactorily serve the same purpose.

Single-Unit Power Plant and Substation at Alton, Ill.

The East St. Louis & Suburban Company Has Completed a Unique Addition to Its System Which Is Tied in with the Existing Steam Station and the Keokuk Hydroelectric Development

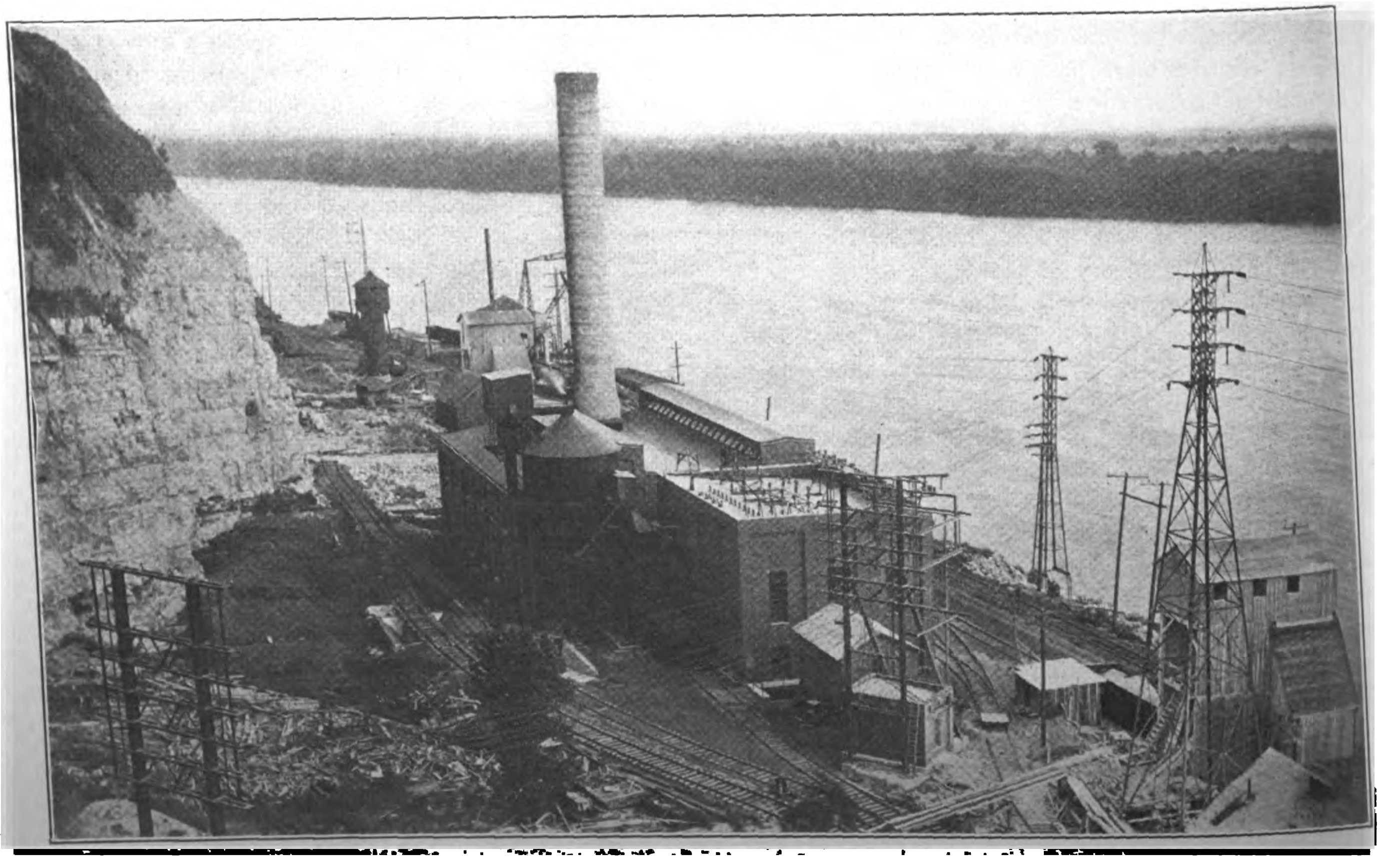
An addition to the generating system of the East St. Louis & Suburban Company, which is replete in unique features, has just been completed at Alton, Ill. Essentially, this installation includes a single-unit, 5000-kw steam generating plant supplying power to the railway, lighting and power transmission and distribution system, and a 6000-kw substation connected through a 66,000-volt a.c. transmission line with the hydroelectric plant at Keokuk, Ia. The power from the steam and the hydroelectric stations is transformed to 13,200 volts, and the lines connect with those from the Winstanley steam station of this company at East St. Louis, Ill. Power is supplied to 185 miles of city and interurban lines radiating from East St. Louis, Ill., as well as to lighting and power circuits in the territory served by the railway system. At Alton is also a terminal house from which transmission lines, carried on steel towers, lead to East St. Louis, a distance of 27 miles.

STEAM STATION ARRANGEMENT

A fireproof building on concrete foundations with red pressed-brick walls, and floors and roof of ferroinclave concrete construction, houses the steam station generating units. This building is divided into generator room and boiler room, each provided with a basement. In the engine room, 42 ft. x 112 ft. in size, is a 6250-kva 600-volt, twenty-five-cycle, General Electric generator, driven by a five-stage, horizontal Curtis turbine operating at 1500 r.p.m. The neutral of the generator is grounded. The generator terminals are connected to a three-phase, 3125-kva auto-transformer, which steps up the voltage to 13,200, and the high-tension terminals are connected, through a three-phase, 300-amp, 15,000-volt oil switch, to the 13,200-volt bus in the substation. The station is designed for an ultimate capacity of 10,000-kw and, with but slight changes, it can be arranged to house machinery of double this capacity. Practically two-thirds of the generating room is occupied by a synchronous condenser, two frequency changers, two synchronous converters, two motor-driven exciter sets, a steam-driven exciter, switchboards and control apparatus. An overhead, 30-ton, electric traveling crane serves the entire generating room.

MOTOR-DRIVEN VERTICAL PUMPS

An Alberger 8200-sq. ft. Spiroflo surface condenser, installed beneath the turbine, is connected to it by a 52-in. x 17-in. expansion joint. Circulating water is supplied to this unit through a syphon-type system, and is lifted from the Mississippi River by an 18-in. vertical centrifugal pump, driven by a 100-hp, 250-volt, d.c. variable-speed motor located on the engine-room floor. This pump has a capacity of 9000 gal. per minute against a total head of 16 ft. when operating at 395 r.p.m. Since the Mississippi River is free from sand bars and other obstructions at this point, it was possible to lay the 18-in. intake pipe, fitted with flexible joints, directly on the river bottom. To prevent large particles of foreign matter from entering the intake system, however, the end of this pipe was provided with a coarse screen, and in addition a twin strainer was placed inside the station. In order to provide for



EAST ST. LOUIS & SUBURBAN PLANT—GENERAL VIEW OF PLANT AND SURROUNDINGS variations in the load on the turbine and in the stage and temperature of the river water, the motor driving the circulating water pump was chosen to permit a variation in speed from 350 r.p.m. to 750 r.p.m. A rotary dry-vacuum pump, 12 in. x 30 in. x 18 in. in size, handles the non-condensible vapor in the condenser, while a steam-turbine-driven, hot-well centrifugal pump removes the condensate from the condenser and lifts it to the overhead feed-water storage tank in the boiler room.

125-250-VOLT EXCITERS

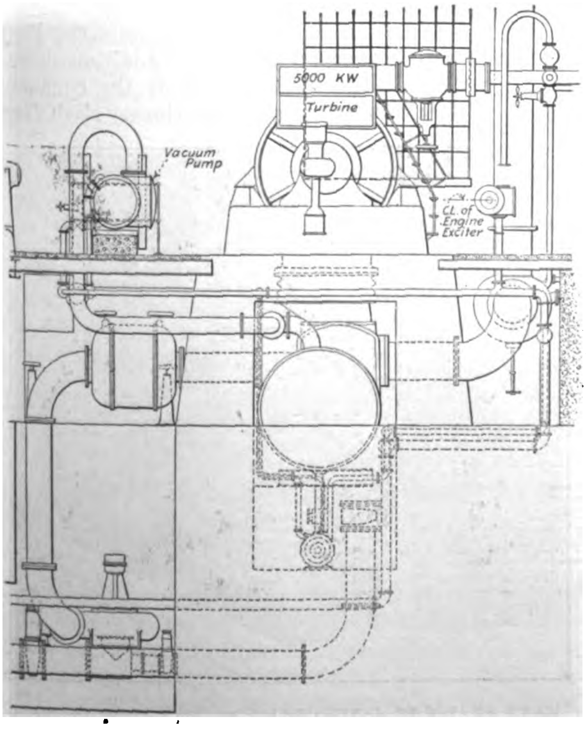
As it was desired to use 250 volts d.c. for the motors driving the circulating pump, the coal-weighing hopper and the traveling crane, three-wire, 125-250-volt exciter units were selected. There are three 75-kw exciter sets, two driven by 220-volt, three-phase, twenty-five-cycle induction motors, and the third by a steam engine. Double exciter buses were installed so that a portion of the machines may be excited from one bus while the others receive their excitation from the second bus. The exciters were so connected also that they can supply power to the station lighting system in emergency. A storage battery used in the operation of the remote-control oil switches is also connected to automatically supply energy for switchboard lighting when the station voltage falls below a predetermined limit.

SYNCHRONOUS CONDENSER FOR POWER FACTOR CONTROL

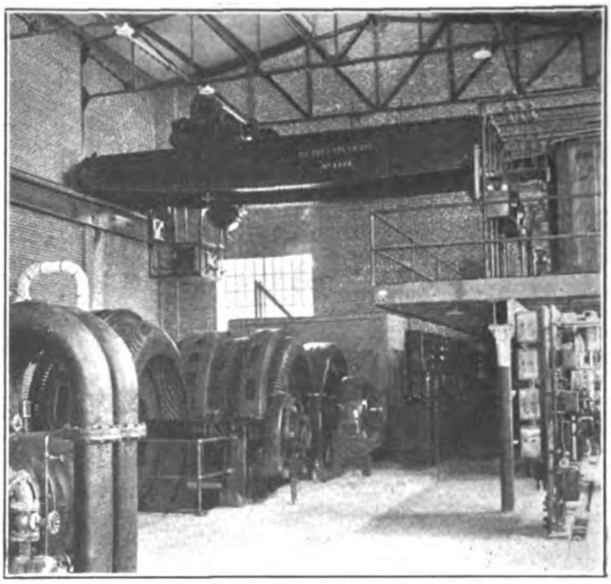
The substation equipment located in the power plant includes a 13,200-volt synchronous condenser connected to one section of the ring bus and designed to permit the maintenance of constant potential and high power factor on the railway end. There are also a frequency changer rated at 500 kw and another rated at 1000 kw, used to supply fifty-cycle power for motor service and light in Alton, and a 500-kw, 600-volt synchronous converter for railway lines in Alton. Another converter of the same capacity has been provided for.

SWITCHBOARD ARRANGEMENT

The twenty-five-cycle switchboard is divided into five sections, namely, one controlling the twenty-five-cycle, 13,200-volt equipment and the twenty-five-cycle 66,000-volt equipment; another the sixty-cycle, 2300-volt equipment; a third, the 600-volt d.c. railway unit, and a fourth for the arc lamp and the exciter sets. The fifth is a twenty-five-cycle, 220-volt panel for controlling the low-tension a.c. circuits to the various motor-driven auxiliaries.



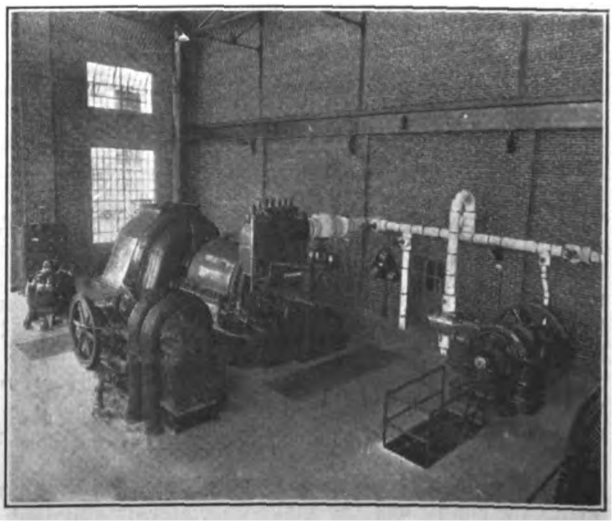
EAST ST. LOUIS & SUBURBAN PLANT—DETAILS OF TURBINE CONDENSING EQUIPMENT



EAST ST. LOUIS & SUBURBAN PLANT—FREQUENCY CHANGER END OF TURBINE ROOM

Each panel is a separate pedestal separated from its neighbor approximately 4 ft. Seven pedestals with the synchronizing post, have been installed. One post at the end of the row of pedestals supports a swinging bracket carrying a synchroscope, a frequency indicator and two voltmeters. One of the voltmeters is so arranged that it can be connected to any section of the twenty-five-cycle buses, while the other can be plugged into any machine or into the outgoing lines.

Switchboards for the sixty-cycle a.c. and the d.c. railway feeders, the exciter and the synchronous condenser face the switchboard. A balcony over both switchboards carries the oil switches for the sixty-cycle, 2300-volt lighting and power feeders. This balcony also accommodates the transformer and switching equipment for the series arc and the incandescent lighting circuits.



EAST ST. LOUIS & SUBURBAN PLANT—TURBO-GENERATOR AND AUXILIARIES company has also contracted with the Illinois Traction System to install Saxby & Farmer mechanical interlocking plants at four points in Illinois. One of these plants is north of Staunton, where the Illinois Traction System crosses the Wabash, one at Benld, where the Northwestern is crossed, one east of Mt. Olive at the crossing with a spur of the Wabash, and the fourth plant is in Staunton, at another crossing with the Wabash. The signals are mechanically operated and there are no distant signals for the signals covered by the interlocking plant. The signals on the Illinois Traction System stand normally clear, and the plant is equipped with a time lock. The switches and derails are operated by switch and lock movements. Another T.D.B. installation of automatic block signals is being completed on the Cleveland, Southwestern & Columbus Railway near Cleveland, Ohio.

ADVERTISING LITERATURE

Ohmer Fare Register Company, Dayton, Ohio, has issued a circular on fare boxes in which it has summarized the apparent advantages of fare boxes and the general objections to such boxes and has described and illustrated its own safe deposit box.

W. S. Barstow & Company, Inc., New York, N. Y., recently published a thirty-five-page, leather-bound book, giving in convenient form general data regarding public utilities companies under its management. Each company is discussed individually in relation to its geographical location, its intercorporate relations, its capitalization, earnings and expenses for the last fiscal year, franchises, population served and other matters affecting its corporate life. There is also a map showing the exact location and extension of properties of each company. Of the forty-seven companies covered by the book, twenty-nine are electric railways. The company announced that reports of engineers and accountants for the various companies are on file at the main office and that any statistics regarding the individual companies not presented in the book will be furnished to the holders of securities of the companies upon application.

Galena Signal Oil Company, Franklin, Pa., has reprinted in pamphlet form its answer to the quotation in the brief of Louis D. Brandeis, special counsel for the Interstate Commerce Commission, in the rate increase case, in which he referred to economies in the use of oil for lubrication said to have been effected in Panama. In conclusion the company says: "If comparative estimates were made by qualified experts as to the costs per unit of work performed by the railroads, it would be found that the railroads in the United States are lubricating their equipment much cheaper than this service is performed on the isthmus. The inference is that low-priced oils and the supervision given on the isthmus are set up as standards, whereas railroads in the United States have been following this practice of supervision for many years, and if a fair comparison were made with accurate statistics, considering character of service and comparative units of work performed, it would be demonstrated that the railroads in the United States are lubricating at a cost much less than is obtained on the isthmus."

NEW PUBLICATION

Corporate Promotions and Reorganizations. By Arthur S. Dewing. Harvard University Press, Cambridge, Mass. Cloth bound, 615 pages, $2.50.

This book, which is a study of the financial policy of certain individual corporations which at one time or another have found it necessary to undergo a reorganization of their capitalization, is a scholarly contribution to the literature of trusts and corporation finance. The major portion of the book is devoted to a detailed study of a selected group of industrial corporations, each of which has passed through the cycle of promotion, failure and reorganization. The consolidations discussed are: the United States Leather Company, the starch consolidations, the glucose combinations, the National Cordage Company, the Westinghouse Electric & Manufacturing Company, the National Salt Company, the United States Realty & Construction Company, the American Bicycle Company, the American Malting Company, the New England Cotton Yarn Company, the cotton duck consolidation, the asphalt consolidation, the United States Shipbuilding Company and the American Glue Company. The cases chosen, while not exhaustive, serve to illustrate best all phases of corporate history in a comparatively brief period. The book abounds in notes and tabulated data that give complete information on the smallest auxiliary points.

The chapter devoted to the analysis of the history of the Westinghouse Electric & Manufacturing Company is probably of greatest interest to the electric railway field. The author gives the best exposition of the financial successes and difficulties of the Westinghouse Company that has ever appeared. As Mr. Dewing states, the history of the Westinghouse Electric & Manufacturing Company is a record of marked achievement in the application of scientific knowledge to practical uses. To the mind of the author, both the strength and the weakness of the Westinghouse Company lie in the inventive genius of its founder. The company has always been strong from the side of technical achievement, but weak from the side of the administration of its finances and its control over the avenues of capital and investment. The main cause for the two reorganizations of the company was the fact that the owners failed to note that a business of large magnitude, even though its credit be excellent, must be fortified by considerable reserves in the form of fluid assets not affected by the ordinary fluctuations in the demand and supply of money. The author notes that the methods used to secure relief in each of the company's reorganizations were identical. In neither instance was the reorganization accomplished through the judicial loss of the property, or was there an exchange of entirely new securities for old, or a new funded debt created. The positive expedients were the same—the merchandise creditors and bankers funded their debt into stock, and new stock in suitable amounts was issued at par. In regard to the future, the author closes with words of optimism.

The last chapters of the book are devoted to a summary of the promotion of consolidations that have undergone reorganizations, of the conditions and causes leading to reorganization and of reorganization expedients. Mr. Dewing states that the link between the promotion of a corporation and its subsequent failure and reorganization often lies in the early management, and in cases where early interests have been willing to forego immediate profits and conserve the funds, the enterprises have been placed on a sound footing. The same problem of conservatism of management presents itself in the period immediately before reorganization in connection with the payment of unearned interest or unearned dividends. In summarizing the reorganization expedients discussed in the book, Mr. Dewing states that most reorganizations have sought to relieve accumulated and unmanageable floating debt brought about by the deflection of money from the needs of the business to the payment of interest and dividend charges. All plans of reorganization have sought to improve the company's position so that the amounts required for interest payments should be within the minimum earnings of the corporation, and the preferred stock dividend records no longer a hopeless burden upon the future credit of the reorganized company.

The *laissez-faire* point of view of the author throughout the book is worthy of notice. He states that he has been impressed in his study of corporate promotions and reorganizations by the powerlessness of mere aggregates of capital to hold monopoly and also by the tremendous importance of innate individual ability or its lack in determining the success or failure of any enterprise. With these observations in mind, the author hazards the belief that whatever trust problems exist will work out their own solution. Legislative regulation is liable to perpetuate the unfortunate corporation by furnishing an artificial prop to support natural weaknesses. It is on this point that other men may take issue with the conclusions of the author.

While unfortunate management and vigorous competition may have worked out the disintegration of some trusts, in the case of combinations having a wide monopoly of raw material or patent rights and possessed of enormous capital, these forces may work out too slowly to make a passive policy of dealing with them advisable.

Electric Railway Journal

Published by the McGraw Publishing Company, Inc.

Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY, AUGUST 15, 1914 No. 7

FINING RAILROAD TRESPASSERS IN ILLINOIS The move to arrest and fine all trespassers on Illinois railroad property, recently made by the Public Utilities Commission of Illinois with the consent of Governor Dunne, cannot be commended too highly. To this end municipal and railroad authorities have been instructed to arrest all trespassers. While railroads, both steam and electric, have taken every possible precaution to reduce the number of trespassers to a minimum, they have not been aided by the state or local authorities. Accordingly, this move is of great importance to them, and it is to be hoped that it is merely the beginning of a national campaign. When it is considered that more than one-half of the people killed by railroads in the United States are trespassers, it should be cause enough to make trespassing not only illegal but subject to fine. The fact that these trespassers illegally were on dangerous ground did not serve as sufficient notice to keep them from using railroad right-of-way as public thoroughfare. On the other hand, railway companies are being forced to take every precaution to protect their passengers, hence it seems right and proper that the public should be forced to protect itself in this matter.

DISCUSSIONS ON THE WAR One of the companies in a large city has given instructions to its trainmen to refrain from discussion of the war. The very good reason stated by the management is that as this is a nation with many elements of foreign birth or descent in its citizenship, disputes may arise easily from casual remarks and the final result might be an outbreak of some nature. The motive behind the order is the same that has led to the discouragement of public gatherings in a large city by adherents of one side or the other. If neutrality is to be preserved successfully, the responsibility for this safe policy will lie not only in the executive officials of the government but also in the rank and file of the population. It is plain that if the confidence which both factions in Europe now appear to have is succeeded, as is likely to be the case soon, by a realization that the cause of one is desperate, there may be an effort, both from Europe and from sympathizers in this country, to drag this nation into the conflict. Neutrality is easy to preserve under the present conditions, but it may be less easy if pressure should be directed against this country. It is hard to restrain trainmen from expressing their feelings, but in observing the strict neutrality which should prevail, it is desirable that the dangers of the contrary course be appreciated. Trainmen are in close contact with the public at all times and will be provoked or tempted to reply to sallies. Later, when bitterness succeeds the first sentiments of surprise and horror inspired by the war, it will be still harder to keep from talking. Whether or not companies issue strict orders to their men in this matter, they will improve their own position with the public by discouraging argument with passengers.

EXPORT TRADE DURING WAR The present European war should eventually redound appreciably to the benefit of American manufacturers. The countries now involved in war have in general been our smallest patrons of electrical apparatus, owing chiefly to the operation of protective tariffs. The exception to this is England, where American manufacturers have been compelled to meet the competition of German exports. On the other hand, Canada, Japan, Mexico, South America, South Africa, East Indies and China have all been good customers, and we still have access to their markets. If the English admiralty plans result in keeping the high seas clear for English shipping, our manufacturers will probably do a fairly large export trade with that country, for supplies from Germany will be held back by blockade. There are some latent possibilities in Italy also, provided the Italians succeed in maintaining their condition of neutrality in Europe. The export trade in strictly electrical goods from America has reached a height of more than $25,000,000 a year. During the last year or two a slight tendency toward a decline has been in evidence, but exporters have generally looked upon this as a sympathetic reduction caused by a general falling off in the volume of world trade. The present closing of the purchasing markets of Europe affects so small a percentage of our total export trade in electrical appliances that it can easily be omitted from calculations. On the other hand, in the opinions of those who have studied the subject, the electrical export trade of America, which last year reached a total of about $25,000,000 should greatly increase during the next twelve months.

PROBLEMS TO BE SOLVED Before the present opportunity for increasing our electrical export trade can be fully grasped, there are certain problems that must be more fully solved, such as that of packing goods for foreign shipment and that of establishing better credit relations abroad. The safe packing of goods has been a particularly persistent and annoying problem of American shippers in connection with South American trade, but this should not be a difficulty that would long baffle American ingenuity. Much emphasis also has always been placed upon the advantages enjoyed by our European competitors, especially in South America, by virtue of their longer credits. During the last few years, however, European and American manufacturers have been brought much closer together in the matter of credits. The Germans have displayed a tendency toward a retrenchment from a previous rather excessively liberal policy regarding credits, and American merchants have shown an appreciable relaxation from their former rigid cash policy. Our principal commercial agencies have established branches or chains of correspondents throughout South America, and some of our largest banks have developed their own foreign credit departments. It must be admitted that the average merchant has not yet been clearly educated up to using our existing South American credit system and European manufacturers still have the advantage of service by branches of important home banking institutions. Nevertheless, the progress that has already been made in South America in the face of competition, seems to us an auspicious sign of the complete development that should now take place in the face of the present restricted competitive market.

THE SPECIFIC VERSUS THE GENERAL

A most striking contrast exists between the majority report regarding the Crosser bill for the government ownership of electric railways in the District of Columbia, abstracted in the ELECTRIC RAILWAY JOURNAL of July 4, and the report recently submitted by the minority members of the District committee. Whereas the bulk of the majority report (thirty out of thirty-five pages, to be exact) was devoted to a general exploitation of economic theories regarding public ownership and only 2 in. to an unsupported conclusion of seven points concerning the District railways, the minority report confines itself specifically to the proposed bill, its faulty construction and the advantages claimed by its proponents. The majority report is at best an incomplete and unauthoritative discourse on the general principle of government ownership, while the minority report is a complete analysis of the proposal, good or bad, as it relates to the matter actually under consideration. In other words, it deals with the facts. This difference is worthy of note as being characteristic of two modes of thought—the loose and the analytical.

The first part of the minority report deals with several aspects of the faulty construction of the Crosser bill. The point covering the obligation of the city to take over the railways at an award to be made by the Public Service Commission, whether excessive or not, is particularly interesting in view of the fact that out of the total fifteen witnesses in favor of the bill only four discussed the question of cost. As pointed out, it is impossible at present to ascertain what a condemnation award would amount to, but the minority members are quite correct in their assertion that in the light of current decisions the supporters of the bill have no reason for expecting the award to be limited to a bare physical value, exclusive of going concern allowances. Moreover, it is pointed out that the street railways operating within the District of Columbia extend beyond the limits of the District into a territory over which the federal government has no jurisdiction. The commission is empowered to condemn the outlying lines, but no intelligent method has been suggested for so doing and no indication made of the cost that would result.

The loose construction of the entire bill is also exemplified by Section 9 and Section 10. The first of these provides for the operation of the condemned railways under rules not in conflict with existing acts of Congress. Whether the railways would thus become amenable to all existing laws pertaining to the District is a matter of conjecture, but the efficient electric railway manager would not desire even to admit the possibility of employees receiving thirty days' leave with pay annually and thirty days' sick leave annually, and that purchases over $25 in amount should be placed in federal government hands. Section 9 authorizes the appropriation of $50,000 out of the District funds for the expenses of the condemnation proceedings, an appropriation which is not to be reimbursed out of the sale of bonds and which, in the light of the $1,000,000 paid by the City of Holyoke, Mass., for condemnation proceedings to acquire its gas and electric plants, is palpably absurd. It does not require much discernment to see in this very section the entering wedge for a continual chopping into the District funds for money to run the railways under government ownership.

The second main division of the report is devoted to a general refutation of the local advantages of government ownership so nonchalantly asserted by the majority section of the committee. To use the latter's own words: "The experience of the British Isles with city operation of street car lines shows what may be reasonably expected to be the experience here." We had supposed that every schoolboy recognized the worthlessness of the device of analogy as a means of proof except in cases where absolute similarity of structure, education or environment could be shown. Why this fundamental principle of argumentation should be so slighted by representatives in our national halls of debate is certainly not comprehensible. As we have often stated in these columns, the political conditions and ideals in Great Britain and Germany do not obtain in this country, and with all the assumptions one may care to make regarding these countries, no valid argument may be derived in support of the trial of the proposition here.

We are not compelled to be content with such a general rebuttal of the contention of the committee majority, however, for the minority group has taken up one by one and, as far as is possible in a few words, punctured the advantages of municipal ownership for

Washington claimed by the advocates of the bill. Neither in public nor in private operation can there be found any reason for asserting that municipal ownership in Washington would result in a great reduction of fares, or a large increase in wages to correspond to the San Francisco Municipal Railway wages. Even if the railways were bought at the absurdly low $25,000,000 valuation of the parent of the bill and the burden of taxes were dodged by shifting it to the other taxpayers of the District, the granting of the wage increase which has been dangled in the report would mean an annual deficit of more than $250,000, and fare reductions would make the financial disaster still greater. If the railways were bought at any price tending to equal the present market value of the securities, a deficit would be quite possible without either reduction in fares or increase in wages. In regard to improved service and extensions of lines, the minority report pertinently points out that no admissible testimony was offered at the hearing in regard to complaints along these lines. If these or other conditions, such as those of labor and publicity, are now unjust, as the minority members do not believe, then the Public Service Commission should be required to carry out the functions for which it was created.

It is said that universal transfers are desired in Washington. The minority members of the committee frankly say that the city is entitled to this improvement at the earliest possible moment, but they also point out that the Public Service Commission has ample authority to compel free transfers if the railways can afford them. If the excessive cost of such service can be proved, however, it is obvious that universal transfers under municipal ownership would be established only at the expense of other service and at the sacrifice of needed income. If the District of Columbia commissioners realized more deeply their important position as impartial arbitrators between the utilities and the public, as did the New York commissioners in the recent Brooklyn transfer case, they might take some steps to find out the financial possibility of a universal transfer system instead of spending their time in blind advocation of the theory of municipal ownership.

It would be impossible to leave the minority report without referring to the light it throws upon the state of public sentiment in Washington regarding the proposed bill. It may be recalled that one of the witnesses, as previously mentioned in the ELECTRIC RAILWAY JOURNAL, stated that the people of Washington were "overwhelmingly" in favor of the bill, but that during a four-hour session, even though assisted by a city directory, he could name only sixteen people who favored government ownership, four of these being the three public service commissioners and the corporation counsel. Just as entertaining as the above incident is the fact that after repeated invitations, public notices of meetings and prolonged meetings, only fifteen of the 350,000 citizens were interested enough to testify in favor of the bill, and of these fifteen only four were taxpayers, and these four represented a property valuation of only $23,197 out of the total of $380,000,000.

STEEL SHEATHING FOR CAR SIDING

A surprising diversity of opinion exists in regard to the most desirable thickness for the sheet steel that is now so generally used for the side sheathing between the sills and belt rails of electric railway cars. In the case of the semi-steel car, the sheathing on each side acts as a girder supported on the body bolsters to carry the weight of the car body without the aid of side or center sills. The girder has to be reinforced by the belt rail along its upper edge, as the inherent stiffness of such a member is a feature of importance. This may account for the fact that with cars of side-girder construction a thickness of side sheathing of 1/8 in. is widely used, although many cars of this type, notably those of the Chicago Railways and the Pittsburgh Railways, have a side-sheathing thickness of 3/32 in. However, in the case of all-steel cars, side sheathing of 1/8-in., 3/32-in., and 1/16-in. plate seems to be used indiscriminately.

The use of 1/8-in. plate for side sheathing undoubtedly originated from a belief that this was a minimum workable thickness, and that in city service safety against collisions with the poles or wheel hubs of vehicles demanded more resisting power than was supplied by very thin sheets of steel. However, that the use of even 1/16-in. side sheathing is permissible is demonstrated by the stepless cars of the New York Railways. These cars are now being operated upon Broadway in New York City, where the traffic is exceptionally congested, and notwithstanding the very low sides necessitated by the stepless design no difficulty on account of puncturing the 1/16-in. side sheathing has been experienced.

In these cars, of course, the side sheathing does not act as a girder in the commonly accepted meaning of the term. Instead, the entire car side acts as a truss, of which the belt rail is the compression member, and the side sill, which is composed of a 3-in. angle, acts as the tension member. Therefore the side sheathing, when it enters into the truss action of the side at all, is in tension throughout its entire width. No doubt the sheathing, in this case, acts as a gusset plate to hold the posts and belt rail square, but in general the difficulty of riveting such a thin sheet obviously limits its action except for short distances away from the stiffening members.

Certainly the successful operation of the New York cars upon one of the most congested thoroughfares in the country disposes of the argument, so generally heard in favor of 1/8-in. sheathing, that a thinner sheet will not afford the required protection against vehicles. As a corollary, the argument that strains need not be carried up to the letter board or plate also fails, and with it disappears the only logical reason for the popularity of the side-girder construction as opposed to one of all steel. However, even where the side-girder construction is retained there seems to be no longer any good cause for carrying 250 lb. of extra weight in two girder plates that are 1/8-in. thick when it has been so thoroughly demonstrated that 3/32-in. plates will satisfactorily serve the same purpose.

Single-Unit Power Plant and Substation at Alton, Ill.

The East St. Louis & Suburban Company Has Completed a Unique Addition to Its System Which Is Tied in with the Existing Steam Station and the Keokuk Hydroelectric Development

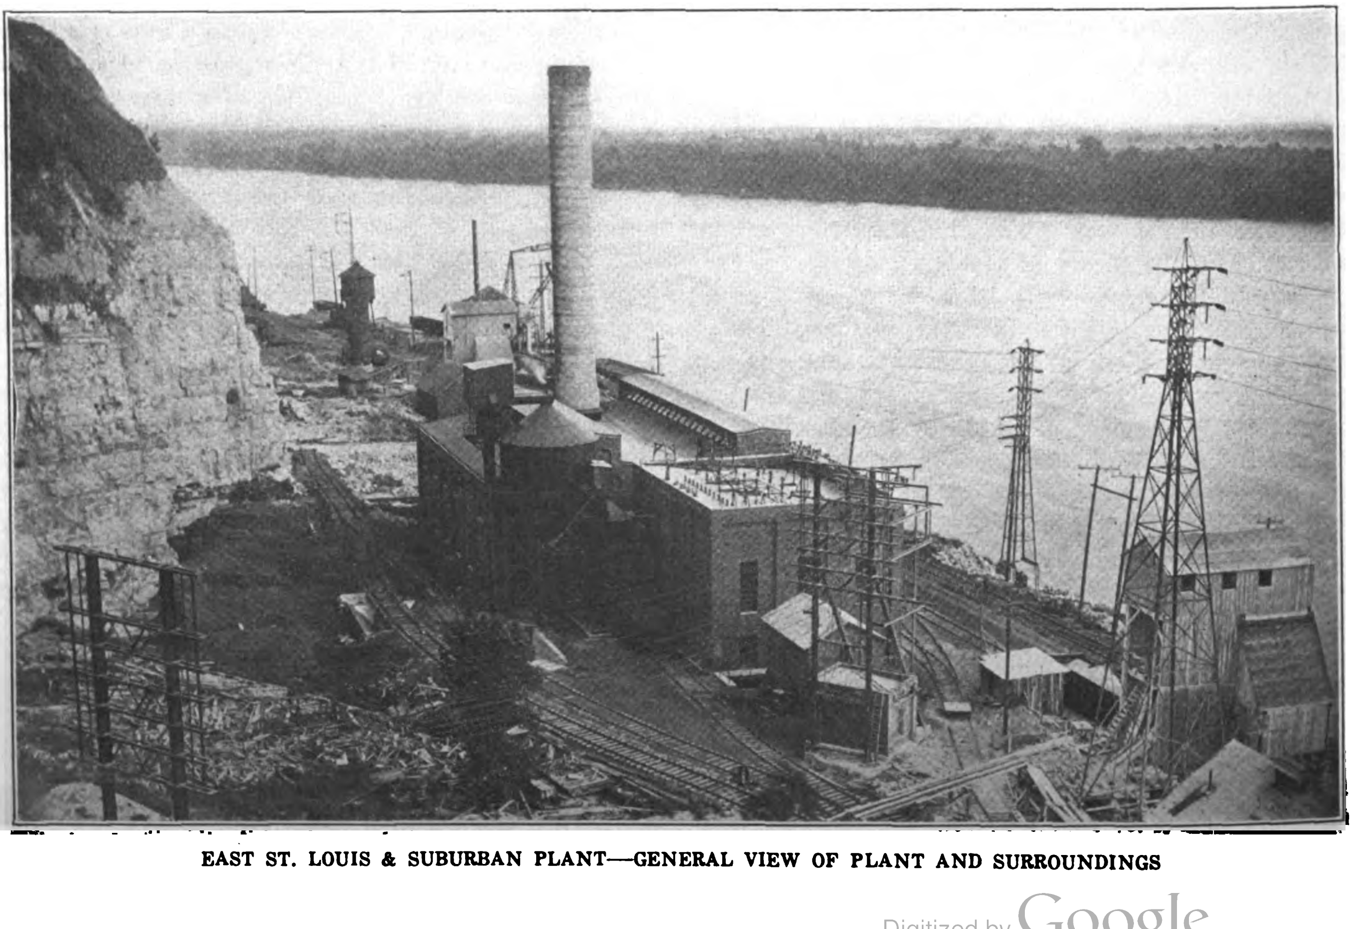
An addition to the generating system of the East St. Louis & Suburban Company, which is replete in unique features, has just been completed at Alton, Ill. Essentially, this installation includes a single-unit, 5000-kw steam generating plant supplying power to the railway, lighting and power transmission and distribution system, and a 6000-kw substation connected through a 66,000-volt a.c. transmission line with the hydroelectric plant at Keokuk, Ia. The power from the steam and the hydroelectric stations is transformed to 13,200 volts, and the lines connect with those from the Winstanley steam station of this company at East St. Louis, Ill. Power is supplied to 185 miles of city and interurban lines radiating from East St. Louis, Ill., as well as to lighting and power circuits in the territory served by the railway system. At Alton is also a terminal house from which transmission lines, carried on steel towers, lead to East St. Louis, a distance of 27 miles.

STEAM STATION ARRANGEMENT

A fireproof building on concrete foundations with red pressed-brick walls, and floors and roof of ferroinclave concrete construction, houses the steam station generating units. This building is divided into generator room and boiler room, each provided with a basement. In the engine room, 42 ft. x 112 ft. in size, is a 6250-kva 600-volt, twenty-five-cycle, General Electric generator, driven by a five-stage, horizontal Curtis turbine operating at 1500 r.p.m. The neutral of the generator is grounded. The generator terminals are connected to a three-phase, 3125-kva auto-transformer, which steps up the voltage to 13,200, and the high-tension terminals are connected, through a three-phase, 300-amp, 15,000-volt oil switch, to the 13,200-volt bus in the substation. The station is designed for an ultimate capacity of 10,000-kw and, with but slight changes, it can be arranged to house machinery of double this capacity. Practically two-thirds of the generating room is occupied by a synchronous condenser, two frequency changers, two synchronous converters, two motor-driven exciter sets, a steam-driven exciter, switchboards and control apparatus. An overhead, 30-ton, electric traveling crane serves the entire generating room.

MOTOR-DRIVEN VERTICAL PUMPS

An Alberger 8200-sq. ft. Spiroflo surface condenser, installed beneath the turbine, is connected to it by a 52-in. x 17-in. expansion joint. Circulating water is supplied to this unit through a syphon-type system, and is lifted from the Mississippi River by an 18-in. vertical centrifugal pump, driven by a 100-hp, 250-volt, d.c. variable-speed motor located on the engine-room floor. This pump has a capacity of 9000 gal. per minute against a total head of 16 ft. when operating at 395 r.p.m. Since the Mississippi River is free from sand bars and other obstructions at this point, it was possible to lay the 18-in. intake pipe, fitted with flexible joints, directly on the river bottom. To prevent large particles of foreign matter from entering the intake system, however, the end of this pipe was provided with a coarse screen, and in addition a twin strainer was placed inside the station. In order to provide for



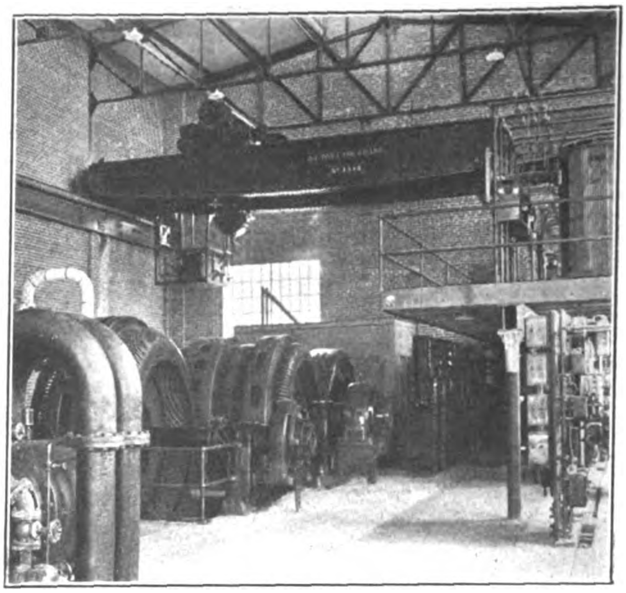
EAST ST. LOUIS & SUBURBAN PLANT—GENERAL VIEW OF PLANT AND SURROUNDINGS variations in the load on the turbine and in the stage and temperature of the river water, the motor driving the circulating water pump was chosen to permit a variation in speed from 350 r.p.m. to 750 r.p.m. A rotary dry-vacuum pump, 12 in. x 30 in. x 18 in. in size, handles the non-condensible vapor in the condenser, while a steam-turbine-driven, hot-well centrifugal pump removes the condensate from the condenser and lifts it to the overhead feed-water storage tank in the boiler room.

125-250-VOLT EXCITERS

As it was desired to use 250 volts d.c. for the motors driving the circulating pump, the coal-weighing hopper and the traveling crane, three-wire, 125-250-volt exciter units were selected. There are three 75-kw exciter sets, two driven by 220-volt, three-phase, twenty-five-cycle induction motors, and the third by a steam engine. Double exciter buses were installed so that a portion of the machines may be excited from one bus while the others receive their excitation from the second bus. The exciters were so connected also that they can supply power to the station lighting system in emergency. A storage battery used in the operation of the remote-control oil switches is also connected to automatically supply energy for switchboard lighting when the station voltage falls below a predetermined limit.

SYNCHRONOUS CONDENSER FOR POWER FACTOR CONTROL

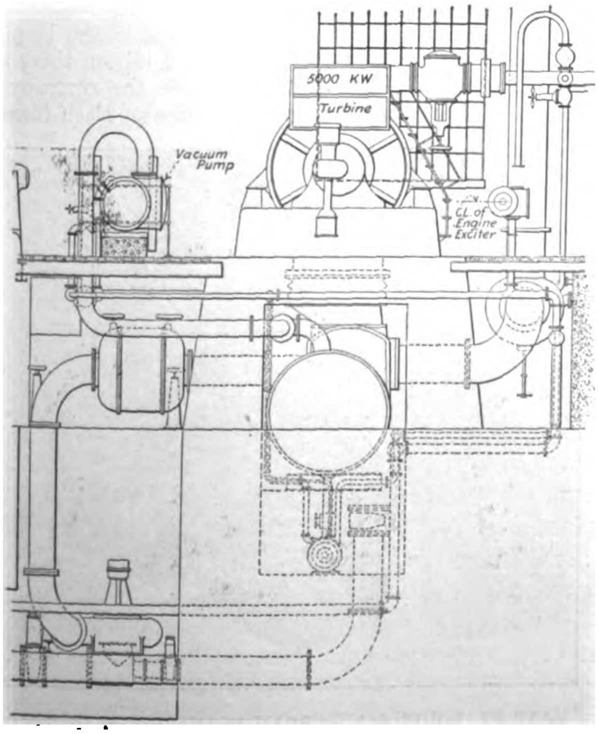
The substation equipment located in the power plant includes a 13,200-volt synchronous condenser connected to one section of the ring bus and designed to permit the maintenance of constant potential and high power factor on the railway end. There are also a frequency changer rated at 500 kw and another rated at 1000 kw, used to supply fifty-cycle power for motor service and light in Alton, and a 500-kw, 600-volt synchronous converter for railway lines in Alton. Another converter of the same capacity has been provided for.



EAST ST. LOUIS & SUBURBAN PLANT—FREQUENCY CHANGER END OF TURBINE ROOM

SWITCHBOARD ARRANGEMENT

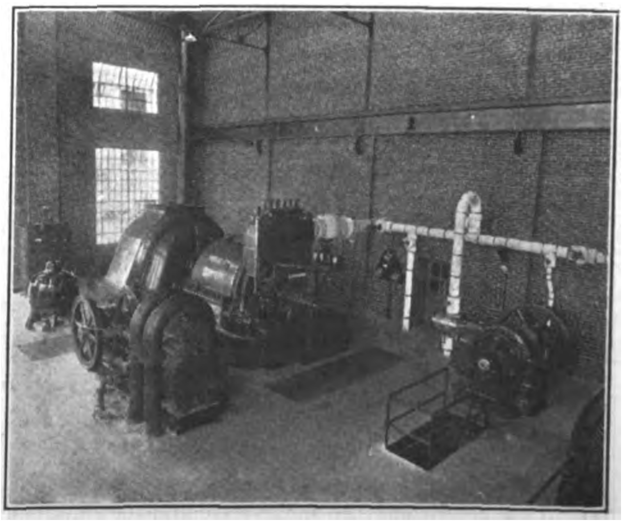
The twenty-five-cycle switchboard is divided into five sections, namely, one controlling the twenty-five-cycle, 13,200-volt equipment and the twenty-five-cycle 66,000-volt equipment; another the sixty-cycle, 2300-volt equipment; a third, the 600-volt d.c. railway unit, and a fourth for the arc lamp and the exciter sets. The fifth is a twenty-five-cycle, 220-volt panel for controlling the low-tension a.c. circuits to the various motor-driven auxiliaries.



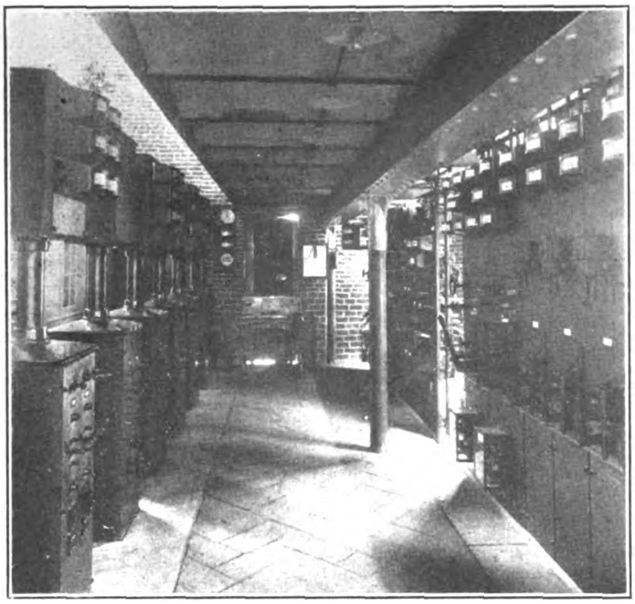
EAST ST. LOUIS & SUBURBAN PLANT—DETAILS OF TURBINE CONDENSING EQUIPMENT

Each panel is a separate pedestal separated from its neighbor approximately 4 ft. Seven pedestals with the synchronizing post, have been installed. One post at the end of the row of pedestals supports a swinging bracket carrying a synchroscope, a frequency indicator and two voltmeters. One of the voltmeters is so arranged that it can be connected to any section of the twenty-five-cycle buses, while the other can be plugged into any machine or into the outgoing lines.

Switchboards for the sixty-cycle a.c. and the d.c. railway feeders, the exciter and the synchronous condenser face the switchboard. A balcony over both switchboards carries the oil switches for the sixty-cycle, 2300-volt lighting and power feeders. This balcony also accommodates the transformer and switching equipment for the series arc and the incandescent lighting circuits.



EAST ST. LOUIS & SUBURBAN PLANT—TURBO-GENERATOR AND AUXILIARIES



EAST ST. LOUIS & SUBURBAN PLANT—SWITCHBOARD SECTION

NATURAL AND INDUCED DRAFT SYSTEMS

A battery of four 440-hp B. & W. boilers, equipped with superheaters, comprises the steam-generating equipment in the boiler room, which is 57 ft. x 96 ft. 6 in. in size. These boilers are designed to operate at 100 per cent overload, thus making the actual total rating 3520 hp. Steam is delivered to a single header at 175-lb. gage pressure with 100 deg. superheat. This header in turn serves all the steam units in the station. Each boiler is equipped with four chain-grate stokers, driven by 3-hp, 220-volt, three-phase, twenty-five-cycle individual motors. The battery is also served by two economizers, having 4018 sq. ft. of heating surface each, and so arranged that ordinarily the gases from two boilers pass through each economizer. The feed-water piping is so connected to the economizers that they are operated in parallel.

Under light loads a 12-ft. x 150-ft. concrete stack will serve the present boiler equipment, but for heavier loads and quick firing a supplementary induced draft fan, driven by a 12-in. x 30-in. Corliss engine, will be used also. This fan will deliver 1000 cu. ft. of air per minute when running at 100 r.p.m. Provision for quick firing was made also as a precaution against interruption in the power supply from the hydroelectric plant.

FEED-WATER SUPPLY AND MEASUREMENT

Boiler feed water is delivered by a gravity system from a storage tank above the boiler room, to a Hoppes exhaust-steam feed-water heater with 625 sq. ft. of heating surface. Ordinarily the water from this heater is pumped to the boilers by a 17-in. x 10-in. x 17-in. Worthington duplex pump of the outside packed type. In cases of light load or emergency, however, a 9-in. x 15-in. x 10-in. pump of the same type performs the work. This pump during ordinary operation is used only for boiler washing. The feed-piping system is arranged so that water may be fed either to the boilers direct or to the economizers.

All of the boiler feed water is weighed by Hammond water meters before entering the storage tank. A 4-in. meter, having a capacity of 75,000 lb. per hour, receives the condensate from the turbine, and a 3-in. meter weighs the make-up water. Under ordinary operating conditions the make-up water is supplied by the cooling water from the turbine bearings and the dry-vacuum pump jacket. Provision is made, however, so that water from the house piping system will be cut in automatically through this 3-in. meter, if the water in the storage tank falls below a predetermined level.

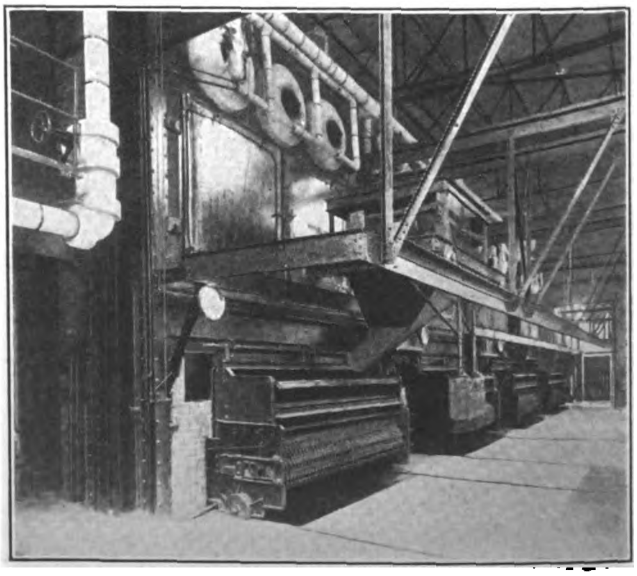
COAL SUPPLY AND MEASUREMENT

Although the East St. Louis & Suburban Railway transports large quantities of coal from the Illinois fields into East St. Louis, it was found more economical to deliver coal to this steam plant by a steam-road connection than to extend the company's own line to the station site for this purpose. Provision for receipt of coal include one track for loaded cars and another for empty ones. In installing these tracks a descending grade to the coal hoppers was provided so that loaded cars could be moved by hand. This same grade permits the "empties" to roll down to the end of the track whence they are removed by the switch engine. All coal is received in bottom-dump cars, which discharge into the track hopper. From this point it is picked up by a flight conveyor and carried to a motor-driven motor or, in case crushing is unnecessary, direct to the bucket elevator, in which it is elevated to a 300-ton steel, concrete-lined storage bunker located just outside the station at the end of the boiler room.

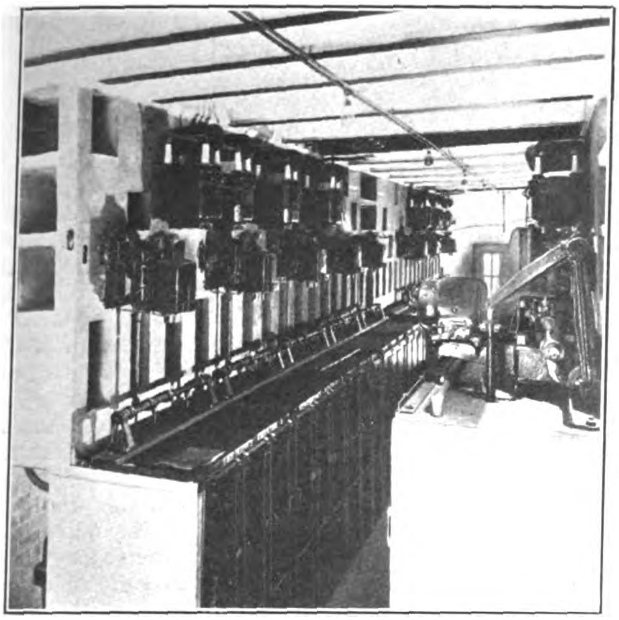
Coal from the bunker flows by gravity into a 2-ton traveling weigh hopper, which is driven by a 2-hp, 250-volt, 1250-r.p.m. d.c. motor, controlled by chains suspended within reach of a man on the boiler-room floor. This hopper is supported on an overhead track immediately in front of the boilers, and discharges coal into the stoker hoppers. Attached to this hopper is weighing apparatus which automatically records the amount of coal dumped into the stoker hoppers. Fine coal and ash from the chain-grate stokers are carried by a chain-drag conveyor and bucket elevator to separate hoppers supported on the same steel structure with the coal-storage bin. The fine-coal bin is so placed that this coal can be discharged into the coal-weighing hopper and again fed to the stokers. The ash hopper is placed above the track so that an empty coal car may be placed beneath it for loading.

DAILY BOILER TESTS

The combined facilities for weighing water and keeping coal and furnace records permit the keeping of continuous efficiency records. In addition there are other instruments installed to enable the company to keep close check on operating conditions. Each furnace



EAST ST. LOUIS & SUBURBAN PLANT—VIEW IN BOILER ROOM



EAST ST. LOUIS & SUBURBAN PLANT—REMOTE-CONTROLLED SWITCHES AND BUSBAR COMPARTMENTS

is furnished with an Ellison differential draft gage; a combination indicating recording and draft gage is so piped that it may serve any or all furnaces, and recording instruments have been installed to record the temperatures of water from the storage tank, the exhaust heater (giving the temperature of the water furnished to the economizer) and each economizer. Instruments also record the temperatures of the gases to and from each economizer, exhaust steam from the turbine, condensate from the condenser, and circulating water from the condenser. The chart for the exhaust steam thermometer record also contains those of temperature and vacuum. The temperature of the circulating water entering the condenser is determined by an indicating thermometer, since it is practically constant.

SUBSTATION WITH TWO SOURCES OF ENERGY

A substation of the same general construction has been erected at the west end of the steam station building. Incoming and outgoing 66,000-volt lines and outgoing 13,200-volt railway transmission lines terminate in this building. The outgoing 66,000-volt line is carried on steel towers of special design, furnished by the Archbold-Brady Company, to the company's substation in East St. Louis. This line is brought through the Alton substation so that all of the 66,000-volt a.c. power received from the Mississippi River Power Company can be measured. There are two 13,200-volt, twenty-five-cycle lines connecting this station with the East St. Louis substation at Lake Avenue. Provision has been made for two 13,200-volt, twenty-five-cycle lines to connect this station with local points in order to supply power to the city and interurban railway lines. But one of these has yet been installed. All of the a.c. transmission lines entering and leaving this substation pass through air-brake switches, the wires entering through bushings mounted on the roof.

The substation building is divided into three rooms; one each for transformers, 66,000-volt switches and 13,200-volt switches. Lightning arresters for incoming and outgoing 66,000-volt a.c. lines and outgoing 13,200-volt lines are installed on a balcony above the 13,200-volt switch room. Two three-phase, twenty-five-cycle, 3000-kva transformers; a three-phase, twenty-five-cycle, 3125-kva auto-transformers; two 13,200/220-125-volt auxiliary transformers, and potential and current transformers for the 66,000-volt metering equipment, are installed in the substation. In the 66,000-volt switch room an oil switch is connected between the incoming line and the bus. One 66,000-volt oil switch is connected between this bus and the 66,000-volt outgoing line to East St. Louis, and an oil switch is provided for each of the 3000-kva transformers.

All remote-control oil switches are installed in the 13,200-volt switch room. The view of this room, reproduced herewith, shows a narrow alleyway with concrete walls on either side. The ring bus is divided into four sections, two of which are carried on each side of the room, supported in concrete compartments. It has been possible by the use of this plan to economize in floor space. In width the room containing the 13,200-volt electrical apparatus is but 13 ft. from wall to wall with an alleyway down the center, 3 ft. 8 in. wide. In the concrete compartments the oil switches occupy the lower cells, while the switch solenoid operating mechanisms are mounted on the front walls of the compartments containing the buses. Cables connecting these switches with the machines and switchboards of the steam station are carried between the two buildings in underground clay conduits.

TERMINAL HOUSE ARRANGEMENT

The terminal house was provided to separate the high-voltage transmission apparatus from the low-voltage commercial and railway circuits. All of the local 2300-volt, sixty-cycle feeders, the 600-volt d.c. railway feeders, and the a.c. arc-lamp feeders which are carried in tile conduits from the steam station to the terminal house, are connected at this point to the outgoing steel-tower lines. The terminal house is 14 ft. square and is placed about 30 ft. from the substation building. It houses the lightning arresters for the feeders mentioned above. From the building the lines lead to a steel tower erected directly over it. From this point special steel towers support the line as it passes from the quarry, in which the plant is located, to connect with the city railway, lighting and power lines. These towers also serve to carry the local 13,200-volt line.

The addition to the generating system of the East St. Louis & Suburban Company described above was erected by the E. W. Clark & Company Management Corporation and will be operated by the East St. Louis Power Company. The construction work was superintended by K. B. Ward, assisted by G. W. McIver, electrical engineer, and H. H. Bailey, mechanical engineer.

Safety Movement in England

The Great Western Railway, England, has recently presented to each of its 80,000 employees a most interesting forty-eight-page pamphlet entitled "The Safety Movement." The introduction gives the railway accident statistics for the United Kingdom, showing what proportion was due to want of caution by the men themselves. The greater part of the book comprises many illustrations with appropriate text to show both safe and dangerous ways of working on locomotives, freight cars, passenger cars, in yards and shops, in baggage rooms, on track jobs, on hand cars, etc. Various safety devices such as goggles and respirators are also described. A detailed tabulation of one month's personal accidents in the various departments of the railway is given at the end with an earnest injunction to all to help in the "safety movement."

Minority Report on Crosser Bill

Abstract of Report Presented on Subject of Government Ownership of Railways in District of Columbia—Faults of Bill Outlined and Asserted Advantages Refuted

The complete minority report on the Crosser Bill, providing for government ownership of street railways in the District of Columbia, noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, is now available. The report was signed S. E. Winslow, Worcester, Mass.; E. E. Reed, Manchester, N. H.; Samuel Wallin, Amsterdam, Pa.; Abraham L. Keister, Scottdale, Pa.; S. F. Prouty, Des Moines, Ia.; T. H. Calway, Jonesboro, Md., and Ben Johnson, Bardstown, Ky. An abstract of the report is published below.

Only two real points were made in support of the contention that municipal ownership is needed in the District of Columbia: That the citizens would be given universal transfers; that the companies are now overcapitalized, and in consequence the traveling public is being cheated out of proper rights which it would obtain under public ownership.

Universal transfers are urgently needed in the District. We believe the quickest and surest way to obtain universal transfers is for the Public Utilities Commission to press energetically a demonstration that the two companies can afford to provide this service. Other efforts to obtain universal transfers may be more spectacular and sensational, but will not be so constructive in result. Condemnation of railways and purchase by the District with the accompanying great expense are not needed to bring this about.

With all the references to overcapitalization, there were not presented to the committee any facts whatsoever to sustain the charge. This Congress has appropriated $100,000 for a physical valuation of these properties. The question of overvaluation, if any, can be intelligently dealt with when the report is made and not until then.

FAULTY STRUCTURE OF BILL

Section 2 provides that condemnation proceedings shall be instituted, and succeeding sections provide that a final award shall be made under one or another course and that the District shall then take over the lines at the amount of the award—whether it should appear to be excessively burdensome or otherwise. There are no data on the probable amount of the award other than the claim of a Washington street railway official that it would exceed $55,000,000, the fact that the market value of the outstanding securities is about $48,000,000, the belief of the corporation counsel that the award ought to be under $30,000,000, and the statement of the proposer of the bill that in his opinion the physical valuation of the properties was about $25,000,000. As a matter of fact the Public Utilities Commission has under way a physical valuation of the properties and finds itself after seven months unable to give the committee any idea whatsoever what the valuation of the properties would be even when regarded only from the standpoint of physical valuation.

The wisdom of condemnation proceedings by the Public Utilities Commission, as provided by Section 4, might properly be questioned, for two of the members openly testified that they were strongly in favor of public ownership of such public utilities and had advocated it for many years, which might naturally preclude their having the open minds of arbitrators. Moreover, none of the three would claim to have expert knowledge of street railway matters. The wisdom of selecting this board is furthermore open to question because of the impossibility of any three men devoting to this problem the exacting study and thought necessary, when they are already burdened with so many other duties which may not be slighted.

Section 5 provides for a possible court review of the award by the Public Service Commission. Without questioning the conclusions of the court, however, an appeal to it would naturally add greatly to the uncertainty of the amount of the award in view of recent court rulings that owners are entitled to a greater amount than the mere physical value of the properties and that the assets of a going concern should be paid for. No testimony was submitted by the supporters of the bill to show any reason for expecting the amount of the award to be limited to what are commonly known as physical values. The majority report virtually assumes that the so-called physical values will alone determine the award. Such an assumption is clearly contrary to present practice; court decisions are quite the reverse. The proposed bill either by design or otherwise absolutely omits all reference to the basis of determining value, which omission clearly indicates general carelessness and complete lack of business acumen on the part of the framers.

Funds for the payment of interest and the redemption of the bonds covered by Section 6 must accrue solely from the net earnings of the street railways, without which the bonds would immediately come into default, apparently. The form and other usual provisions of bonds are not mentioned in the bill. If issued strictly in accordance with the terms of the bill there would be grave doubt as to the responsibility of the District for the payment of interest charges and for the redemption of the bonds at maturity in the event of insufficient receipts from the earnings of the railways to cover such charges. In view of such uncertainty of interest and sinking-fund payments it is difficult to conceive that a market at par or better could be found for any such bonds. On the contrary, it is more than likely that if the bonds were sold at all they would have to be disposed of at a price or prices far below par. This transaction in itself would impose on the railways at the inception a deficit of no mean proportions.

Section 6 further provides that the commissioners must acquire all the lines within the District, but are merely empowered to purchase the parts of lines lying outside the District boundaries. The possible complications which may follow this must be apparent to everyone. The testimony of witnesses failed to bring forth any specific or intelligent suggestion either as to the acquisition of these outside lines in the event of dispute over their values or as to their operation pending purchase negotiations, and all this with no indication of the possible cost.

By the provision of Section 8 the determination of the amount to be paid into the sinking fund each year appears to be optional with the commissioners. There would be no safety, however, in any plan of making payments into the sinking fund except that of paying a definite, uniform and fixed amount each year. The market value of the outstanding securities on April 14, 1914, was approximately $48,000,000. If the commissioners were to purchase the lines at this price and were to sell the proposed bonds at par there would be an annual interest charge at 3.65 per cent on $48,000,000 of bonds, or $1,752,000. If the sinking fund were advantageously invested at 3 per cent interest, compounded semi-annually, the annual deposit to the credit of the sinking fund would be $1,166,533. Thus the annual charges on an issue of $48,000,000 of bonds would be $2,918,533. In 1912, however, the railways paid out a total of $2,266,094.51 for interest and dividends, an amount $652,439 short of an annual fixed charge of $2,918,533. In 1913 the companies paid out for interest and dividends an amount $368,299 short of such an annual fixed charge. The taxes paid by the companies in 1912 amounted to $206,078.85 and in 1913 to $318,063.69. Under municipal ownership these taxes would not have to be paid, and this sum could be applied to meeting annual fixed charges, yet even this would be insufficient to make up the shortage.

Section 9 provides for the operation of the lines by the commissioners of the District under rules not in conflict with any existing law of Congress. The point has been raised that this provision may be interpreted to apply to the operation of street railways all existing acts of Congress relating to the District of Columbia. This would apply the eight-hour law for all employees, would give all employees thirty days' annual leave with pay and thirty days' sick leave annually, would prohibit the insurance of any property, would place in the hands of a departmental committee of the federal government the purchase of all supplies of more than $25 in amount, and would restrict the operation of the railways in various other legal and commercial ways.

In regard to the appropriation of $50,000 for the expenses incident to the condemnation and taking over of the lines, as provided in Section 10, it may be said that not an estimate was submitted to the committee by anyone as to the probable expense of the proceedings. The Public Utilities Commission, not being a board of experts, would have to call to its assistance innumerable experts, such as accountants, engineers, real estate appraisers, etc., to give very complete and detailed reports on the great number of points involved. Then, in the almost certain event of an appeal to the courts from its award, the commission would be compelled to defend its award at very heavy expense for counsel, experts, court expenses, etc. Numerous other items of expense are also apparent.

United States Commissioner of Labor statistics are given on the ratio of these preliminary expenses in the acquisition of various municipal lighting plants. The four largest plants show a percentage of 1.66 to the total cost of the plant, which in this case would mean preliminary expenses of $500,000 to $800,000. This indicates that the proposed amount of $50,000 is in itself an absurdity and only further emphasizes the hit-or-miss character of the whole bill. Furthermore, this money is to be appropriated out of the District funds with no provision for reimbursing the District out of the sale of the bonds or otherwise, thus at the very outset establishing the practice of dipping into the District funds raised by taxation.

ALLEGED ADVANTAGES OF THE BILL

Seven advantages which would accrue to the District by the municipal ownership and operation of the street railways have been set forth by the supporters of the bill, the first being "a great reduction in fares." The rate of fare now paid by most passengers in the District is 4 1/6 cents, or 6 tickets for 25 cents. This is lower than in most large cities of the United States. The average fare paid by all revenue passengers is very close to 4 cents. In 1913 the Capital Traction Company carried 53,425,152 revenue passengers for $2,295,956.41 at an average fare paid of 4.03 cents. Such figures as are available for the other company indicate practically the same average fare. The only basis for a reduction of fares is the hope that an award by the courts would make it possible to buy the railways at an amount considerably lower than the market value of the outstanding securities on April 14, 1914—$47,798,102.

The wage increase proposed by the supporters of the bill would in itself make any reduction of fares impossible. The report of the majority of the committee contrasts the rate paid in Washington to motormen and conductors, an average of 23½ cents an hour, to that paid in San Francisco on the one street municipal line, 37½ cents per hour. Such an increase in wages would cost the District railways more than $1,500,000 a year. If the District can buy the railways for the lowest price suggested—$25,000,000, which is about half the market value of the outstanding securities—such an increase of wages would absolutely prevent any reduction in fares. The present earnings of the road are just sufficient to meet operating expenses, pay taxes of $318,063.69, and leave $2,550,234.94 available for interest and dividends. If the municipal railways paid $1,620,169 for fixed charges and granted a wage increase of $1,500,000 the combined sum would be $3,120,169, giving a shortage of $569,934.06. By not paying taxes this would be reduced to $251,871.06. On the basis of 1913 a reduction of 1 cent in fares would mean a decreased revenue of $1,075,000, and a reduction of half a cent in fares a decreased revenue of $537,000. The extreme unlikelihood of any reduction of fares is obvious from the fact that if the railways are bought at the present market value of the securities a deficit is quite possible without either reduction in fares or increase in wages, while if they are bought at the figure of $25,000,000, practically at half price, the wage increase suggested would make a deficit in itself, and fare reductions would simply make the financial disaster more complete.

The evidence submitted regarding municipal railways elsewhere gives no assurance of reduced fares. The San Francisco Municipal Railways operates through a very productive territory and charges 5-cent fares, with the provision of half fares for school children during certain hours, a practice quite common in the United States. The municipal railway in Monroe, La., charges 5-cent fares. Several cities in the newly developed western section of Canada have municipally owned street railways, the largest being Edmonton. Heavy annual deficits there have recently forced a return to 5-cent fares. Illustrations of lower fares in Great Britain and other European countries are worthless, for different conditions of length of ride, number of available cars, wages, etc., offer no intelligent basis for comparison.

The second advantage claimed is "an improvement in service." Not the slightest bit of evidence was presented to the committee to the effect that service in the District of Columbia is not equal to the best in other large cities, whether the companies are operated under private ownership in the United States or under private or public ownership in foreign countries. The evidence showed that the Public Utilities Commission has already issued more than 600 orders or suggestions of changes to one company and only two have been resisted by the company, both of which may yet be enforced by the courts if found reasonable. If the service is unsatisfactory, the remedy for its improvement is at hand in the Public Utilities Commission law passed for this very purpose.

"More rapid extension of lines" is given as the third advantage. No unprejudiced testimony was presented to the committee to show that the existing companies were not extending lines as readily as other private companies and much more readily than municipally owned foreign companies, or that they had refused any reasonable petitions on the part of the public for extensions. One witness protested against the refusal of the companies to extend lines in his section, but ultimately he admitted he was an executive officer of a real estate development company.

The fourth claimed advantage is "increase of traffic due to lower fares and improved service." It is purely a speculation that any more people would be riding if fares were slightly or even materially reduced—a theory not based on available facts, testimony or evidence.

"Improvement in conditions of labor" is given as the fifth advantage. The testimony indicated that labor conditions on the street railways in the District were on a parity with other labor conditions in the District. If the conditions are unjust, the Public Utilities Commission and Congress should exhaust all possible means for an improvement before resorting to the financial hazard of municipal ownership.

"Full publicity of cost and value," the sixth advantage, should be obtained by the Public Utilities Commission. If that commission has not sufficient power, an appeal to Congress for further authority would surely be granted. Authoritative evidence was presented in the hearings to the effect that municipally owned utilities are more likely to err in this matter than privately owned public utilities.

"Change of purpose from private profit to public service" is given as the seventh advantage, but it is no advantage. Every improvement in service would be an advantage, but with equally good service from privately owned and publicly owned utilities it is a distinct disadvantage to close up an avenue of opportunity for American individual enterprise. A comparison of efficiency of employees of privately owned utilities with those of government offices will not be to the credit of the public employees.

PUBLIC OPINION IN THE DISTRICT

The report states that definite resolutions in favor of the Crosser bill were not submitted by any one of the score or more of citizens' organizations in the District. On the contrary, one presented resolutions against it and a number were reported as voting against going on record. Only fifteen witnesses appeared in behalf of the bill. The report contains a schedule showing the occupations of these witnesses, complaints against present operation, reasons for interest in bill, general arguments in favor of the bill, tax assessments, opinions concerning purchase regardless of cost and number of years in favor of municipal ownership. Of the fifteen witnesses, one complained against the present rate of fare, one against the number of cars running to the suburbs, two against crowds in rush hours and one against the refusal to build a suburban extension. The remainder of the witnesses either would not discuss this phase of the question or had no complaint to make. With one exception every witness expressed his firm belief in public ownership of public utilities as a general proposition, and a cross-examination as to the number of years they had been in favor of municipal ownership showed that the force behind the bill was almost all consistent and long-time advocates of municipal ownership.

The fifteen witnesses out of a total population of 350,000 represented a taxation assessment of $123,197 out of a total assessed valuation of $380,000,000 in the District. The above-mentioned tax assessment for the fifteen witnesses, however, was confined to four persons, the remaining eleven not being at all assessed. It is stated in general that efforts made by the committee to learn of any public demand for the Crosser bill were not successful other than in demonstrating that no public sentiment in favor of the bill existed.

MUNICIPAL OWNERSHIP IN GENERAL

In concluding, the minority report states that the evidence submitted has not been conclusive on the question of the success of municipal ownership of electric railways. Data from a 9-mile street railway in Monroe, La., were very scanty. A municipal line in New Orleans must be excluded from consideration, for it is merely a belt line for the transfer of freight from one terminal to another. As for the municipal line of San Francisco, when the annual redemption of bonds must be met, the net profits from operation would be inadequate to pay the costs of operation and all the other charges if the railway did not save $40,000 or more in taxes and services from other city departments. With this saving of $40,000, although at a like expense of other departments of the city, the lines may even then fail by a few thousands of dollars annually to meet all charges, on the basis of the present receipts and expenses. There appears to be no great inspiration for Washington in this example of municipal railways. James Dalrymple, general manager Glasgow Corporation Tramways, at one time expressed his opinion that municipal ownership of street railways should be successful in the United States, but after a visit to the United States and personal inquiry into American conditions he said: "What I have seen here, and I have studied the situation carefully, makes me realize that private ownership under proper conditions is far better for the citizens of American cities."

Ten Commandments of Safety

At the Lorain Steel Company's plant at Johnstown, Pa., the following ten commandments have been adopted for the guidance of the employees:

1. Thou shalt have no other thoughts than thy work.
2. Thou shalt take no unnecessary risks, nor try to show off, nor play practical jokes, for by thy carelessness thou mayest do injuries which will have effect unto the third and fourth generations to follow.
3. Thou shalt not swear, nor lose thy temper when things do not come just right.
4. Remember that thou art not the only one on the job and that other lives are just as important as thine own.
5. Honor thy job and thyself that thy days may be long in employment.
6. Thou shalt not clean machinery while it is in motion.
7. Thou shalt not watch thy neighbor's work, but attend to thine own.
8. Thou shalt not let the sleeves of thy shirt hang loose, nor the flaps of thy coat be unbuttoned, as they may get caught in the machinery.
9. Thou shalt not throw matches or greasy waste on the floor, nor scatter oil around the bearings, as a dirty worker is a clumsy worker, and a clumsy worker is a menace to his fellow workers.
10. Thou shalt not interfere with the switches, nor the dynamos, nor the cables, nor the engines, nor anything else thou art told is dangerous.

The Mayor of Portland, Ore., recently requested a committee composed of prominent men of Portland to investigate the general condition of the city and report to him with suggestions and recommendations to make Portland a safer city. B. F. Boynton, claim agent Portland Railway, Light & Power Company, was elected chairman.

Rolling Stock for Montreal Tunnel and Terminal

The Present Article Describes the Locomotives and Motor Cars for This 2400-Volt D.C. Electrification—The Locomotives Are Similar to the Butte Design but Are Geared for a Speed of 45 M.p.h..—The Motor Cars Are of Steel for Suburban High-Speed Service

BY W. C. LANCASTER, ELECTRICAL AND MECHANICAL ENGINEER MACKENZIE, MANN & COMPANY, LTD., MONTREAL

In the March 14 issue of the ELECTRIC RAILWAY JOURNAL the writer described the causes leading up to the choice of 2400 volts direct current for the electrification of the Canadian Northern Railroad at Montreal.

The electric rolling stock for the operation of the tunnel and terminal will consist of both electric locomotives for hauling the trains ordinarily operated by steam, and multiple unit cars to maintain a quick and frequent service between the main passenger terminal in the city and the country just west of Mount Royal, which, it is expected, will be rapidly built up and form one of the most attractive suburbs of Montreal.

LOCOMOTIVES

The 2400-volt d.c. locomotives are substantially the same in appearance and dimensions as those of the Butte, Anaconda & Pacific Railway, which were illustrated in the ELECTRIC RAILWAY JOURNAL for June 7, 1913, page 1010. As the schedule for the locomotive trains does not call for high speed, it was not thought necessary to resort to any of the special methods of connecting the motors to the driving axles, such as are used on the side-rod and gearless types. The motors will be nose-supported in the usual way and geared to the axle by means of twin gears.

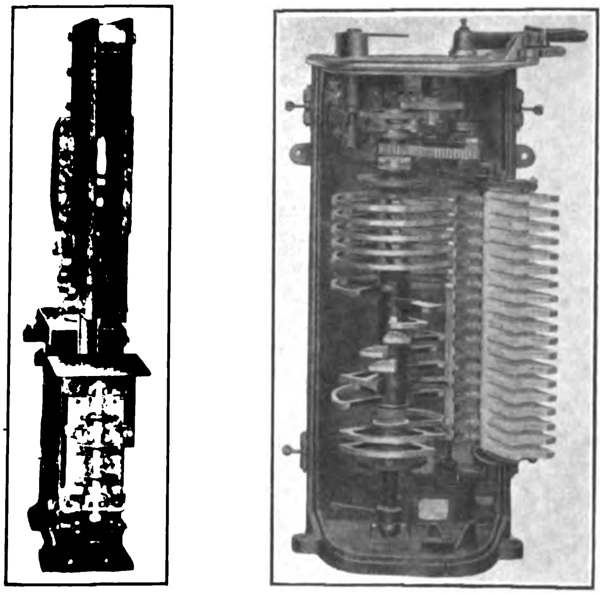
The locomotive has four axles with all the weight of the locomotive upon the eight driving wheels. The running gear consists of two four-wheel trucks, articulated together by a heavy hinge. The equalization of the trucks is accomplished by a semi-elliptic leaf spring over each journal box, connected through spring hangers to the frame and to the equalizer bars. The equivalent of a three-point suspension is thus obtained through the side equalization of one of the trucks and both side and cross equalization of the other truck.

The friction draft gear is mounted in the end frame casting of the truck. The cab, which is of the box type, is divided into three compartments, the center compartment for the apparatus and the two end compartments for the operator.. Each operator's compartment is supplied with controller, control switches, ammeter, air brake and pantograph control, air gages, 2400-volt cab heater, bell rope and control for the whistle and sanders, thus providing the locomotive with complete double-end control.

The motor equipment consists of four GE-229A commutating pole motors wound for 1200 volts and insulated for 2400 volts, two of these motors being permanently connected in series for operating on the 2400-volt trolley circuit. The one-hour rating of each motor is 315 hp at 1200 volts. The motors are designed for forced ventilation, which is obtained by means of a blower in the locomotive cab. Either pair of motors may be cut out, in case of emergency, by a ~~special~~ handle on the change-over switch. The locomotives are geared for a free running speed on tangent level track of approximately 45 m.p.h. and are operated as two-speed machines with ten points in series and nine points in series-parallel. The master controller used is of the non-automatic type and has two handles, one regulating the applied voltage at the motors and the other for controlling the direction of rotation of the motors. The rheostats which form the external motor resistance are placed near the roof of the cab and provided with ample natural ventilation.

The master controller and contactor energizing circuits are designed for 125 volts. Each contactor is easily accessible without any disturbance to adjacent contactors. A special electro-pneumatic change-over switch is used for making the transition between series and series-parallel connection of the pairs of motors.

The 125-volt current for operating the contactors and for lighting the cab and headlights is obtained from a motor-generator set, the motor of which has two 1200-volt windings and two 1200-volt commutators in series for operation on 2400 volts. This set is mounted in the center cab and also drives the blower for providing forced ventilation to the main motors.



MONTREAL TERMINAL ELECTRIFICATION—CONTACTOR WITH INTERLOCK; MASTER CONTROLLER FOR LOCOMOTIVE

Fuses of the copper ribbon type placed in fuse boxes provide protection for each individual circuit as well as the main circuit from the trolley. These fuse boxes are all arranged to blow into a common chamber designed to take care of the arc. In addition to the fuse on the main circuit, a main switch is also provided. This is of the knife-blade type, being opened and closed by a handle placed in a position for easy operation in case of emergency or when it might be necessary to open the circuit while carrying current. This main switch blows into the chamber provided for the fuses, ~~and has a~~ powerful magnetic blowout.

The trolleys are of the Butte roller pantograph type, pneumatically operated and mounted on insulated bases. Two pantographs are used per locomotive. A hand pump is provided in case a locomotive has been standing for some time and has no air supply.

A Warner speedometer, similar to the type largely used on automobiles but especially designed for locomotives, is located in each operating cab. These will

16¾ in. back to back and fitted with a top cover plate 26 in. x ¼ in. and a main bottom cover plate 24 in. x ⅜ in. The body and end sills are of structural steel shapes. Trap doors of Edwards all-steel construction are installed. The bolsters are built up of plates and angles. The Standard Coupler Company's buffers and Miner draft gear are used.

The flooring consists of a bottom layer of tongue and grooved spruce, on top of which is spread a layer of three-ply "Salamander." Between this and the main floor is an intermediate insulating floor formed of ⅛ in. steel plate, on top of which is also laid a layer of three-ply "Salamander." The main steel floor, on top of which is spread a layer of "Flexotile" composition flooring, consists of "Chanarch" steel.

As regards the side framing, the main side posts are formed of 3 in. x 2 in. x 5/16 in. rolled steel angles acting as a stiffener for the side sheeting and a suitable connection for the wooden side posts. At the belt rail the sheeting is further stiffened by a 4-in. x ½ in. bar extending the full length of the body. The corner posts are built up of 3-in. x 2-in. angles with 3/16-in. pressed steel cover plate extending around and over the side and end sheets. The side sheets are of 0.110-in. thick cold rolled steel plate.

Particular attention has been given to the heat insulation. For the sides, roof and ends of the car this insulation consists of three-ply "Salamander." It is secured to the steel by means of glue and the Cleveland Tack Company's "Clinchtite" nails spot-welded to the sheet steel and provided with steel retaining bands. This method is similar to that used by the New York, Westchester & Boston Railway.

The trucks are of this railroad's plate frame construction built for a center plate capacity of 40,000 lb., and they are of the side equalized type. Case-hardening is applied for all hangers and rod jaws, for all pin ends of levers and where all holes occur in the same. The

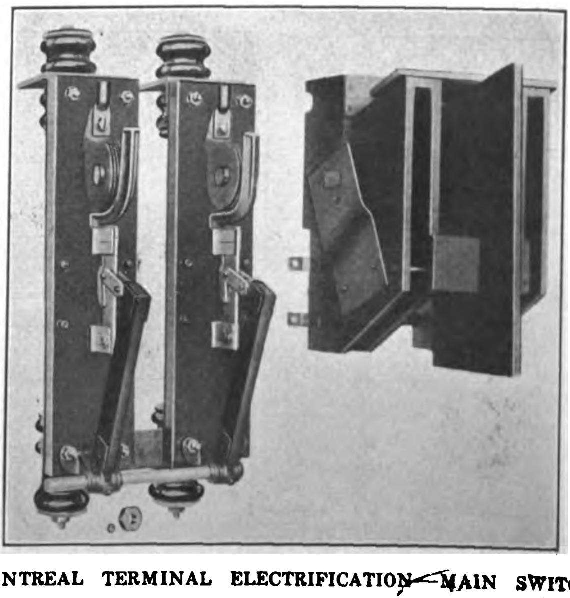
MONTREAL TERMINAL ELECTRIFICATION — TRUCK FOR MOTOR CARS



MONTREAL TERMINAL ELECTRIFICATION—MAIN SWITCH wheels are of rolled steel and are 36 in. in diameter. The journals are 5½ in. x 10 in. and of the American Electric Railway Association standard with McCord boxes.

The outside and inside finish and all fittings and other details are made to conform as nearly as possible with Canadian Northern standard practice.

The principal dimensions are given in the following table:

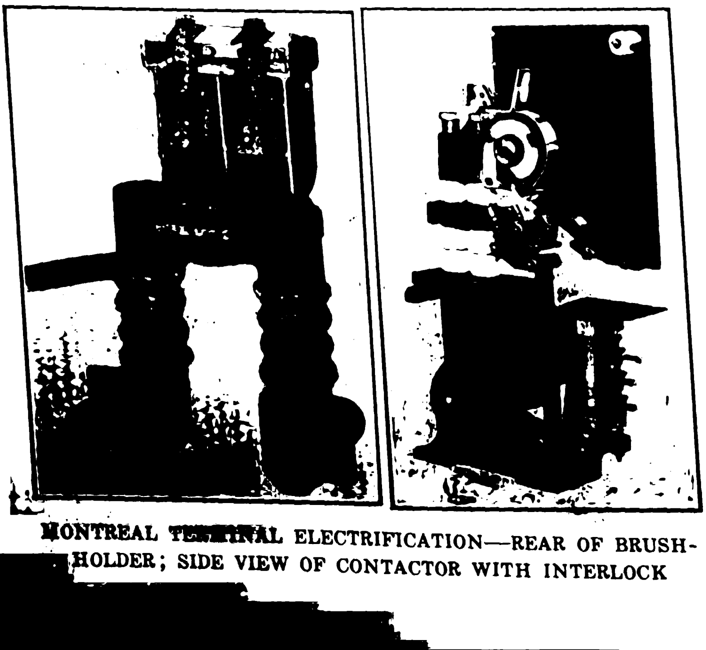
Length over buffers	67 ft.	5¾ in.
Length over body corner posts	57 ft.	6¼ in.
Truck centers	42 ft.	9 in.
Width over side sill angles	9 ft.	10½ in.
Width over eaves	10 ft.	2¾ in.
Height top of rail over roof	13 ft.	0 in.
Height top of rail to underside of side sill	3 ft.	7½ in.
Center to center of body side bearings	4 ft.	10 in.
Center to center deck sills	5 ft.	6 in.

The approximate weight of the car loaded and equipped is 160,000 lb.

The electric hot air system of car heating is used. One complete heater is placed underneath each car and receives its energy direct from the 2400-volt supply. The heater has a capacity of approximately 25 kw and is constructed for two heat combinations so as to provide for the changes in temperature conveniently and economically.

The complete heating equipment consists of the heating unit, blower and regulating mechanism, the controlling switch and thermostat of the regulating mechanism being arranged for operation from the 600-volt supply. Air is forced over the heating unit by means of the blower and distributed to the car through the air ducts along the sides of the car. The blower used for the circulation of the air is operated by a motor which is connected in series with the heating unit on the ground side. The capacity of the blower is approximately 1000 cu. ft. of air per minute.

The motor equipment consists of four fully ventilated GE-239A, 125-hp, 1200-volt commutating pole motors insulated for 2400 volts. Two of these motors are permanently connected in series for 2400-volt operation. Ventilation of the motor is accomplished by drawing air into the armature at the pinion end by means of the fan on the armature shaft. The air passes longitudinally through the whole interior of the motor and is expelled through an opening in the frame at the commutator end. This opening is protected by wire mesh. A back view of the brush-holder and support is also shown.



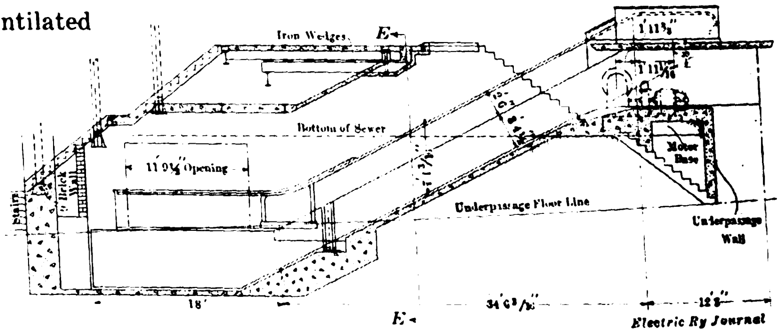
MONTREAL TERMINAL ELECTRIFICATION—REAR OF BRUSH-HOLDER; SIDE VIEW OF CONTACTOR WITH INTERLOCK

The control is of the non-automatic type for multiple-unit operation. The equipment includes a motor-generator set for furnishing 600-volt current for the control circuits, the air compressor and lighting circuits. This set consists of two 1200-volt motors, operating in series on 2400 volts, direct connected to a 600-volt generator. The master controller, contactors, switches, reverser and pantograph are of essentially the same construction and appearance as those already described for the locomotives. The controller will have five steps in series and four steps in parallel. It differs from the locomotive controller in having the usual motorman's operating handle instead of a lever. This handle is provided with means for cutting off power and applying air brakes in case the motorman removes his hand.

Copper ribbon fuses similar to those on the locomotive will be used and an aluminum cell lightning arrester is installed on each car.

Improvements at the Juniper Street Station in the Philadelphia Subway

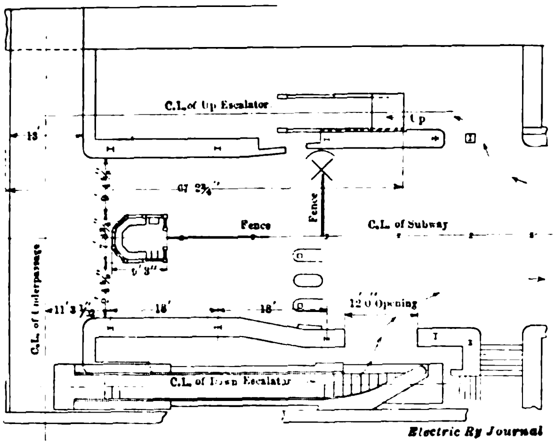
In the Market Street subway in Philadelphia there is a point near the business center where the east-bound surface cars in the subway make a loop under the elevated line cars, which are also in the subway, and return west. Passengers coming in from West Philadelphia transfer at this point if they desire to go farther east, say to the Delaware River ferries. Obviously a considerable part of the traffic terminates at this station, Juniper Street. This underground station has been laid out with a view to making its operation so convenient for passengers that there could be no possible cause for complaint on account of the necessity for using two levels. For this reason a down escalator has been installed between the two levels, in addition



PHILADELPHIA SUBWAY—CROSS-SECTION ESCALATOR WAY, JUNIPER STREET STATION

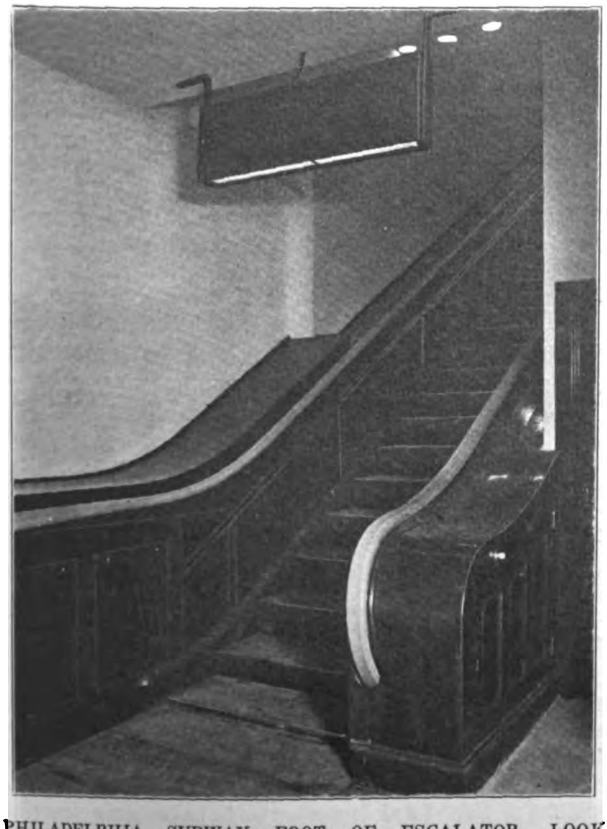
PHILADELPHIA SUBWAY—VIEW OF ENTRANCE TO DOWN ESCALATOR to the up escalator and conveniently placed staircases. The down escalator is very popular in spite of its comparative novelty, very few passengers using the stairway, which they could do with little extra effort.

The accompanying illustrations show some details of the station. One diagram is a plan of the lower level. Passengers entering the lower level direct from the street come in at the left in the figure, secure tickets at the booth shown and pass through the entrance to the large passage at the right which leads to the surface car loading platforms. Outgoing passengers from the lower level can pass out through the turnstile or to the upper level on the up escalator. Passengers from the upper level can reach the lower level either by way of the down escalator or by the stairs directly over it. A section showing the down escalator and staircase is given in a second diagram.

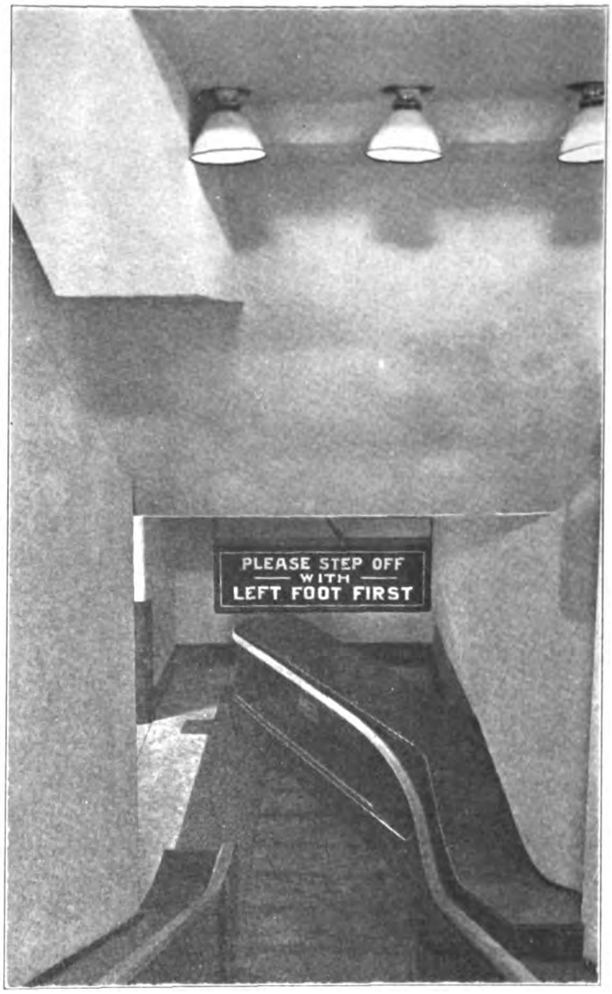


PHILADELPHIA SUBWAY—PLAN OF LOWER LEVEL, JUNIPER STREET STATION

The halftones show details of the down escalator, those from photographs taken at the foot having been chosen to illustrate particularly the method of lighting used. Unusually good light is desirable at this point to avoid confusion due to the novelty of the construction. The escalator way is brilliantly illuminated by lamps mounted in reflectors near the ceiling beams and through openings in the bottom of the illuminated box sign. An usher is located at the bottom of the escalator to assist passengers who may still not understand the method of getting off.



PHILADELPHIA SUBWAY—FOOT OF ESCALATOR, LOOKING UP



PHILADELPHIA SUBWAY—FOOT OF ESCALATOR, LOOKING DOWN, SHOWING ILLUMINATED SIGN

The Juniper Street station involved special structural problems due to the difficulty of underpinning the adjacent buildings. Cross beams much heavier than were needed for floor support were used for this purpose. Space limitations also prescribed a most economical arrangement of staircases, escalators and passageways. The result has been a layout which permits the handling of large crowds with little congestion.

The city of San Francisco is using the cement gun to finish the ornamental concrete poles which are being erected on Van Ness Avenue in San Francisco. The poles are for the double purpose of lighting and carrying trolley wires for the new municipal railway, and the coating is being applied after the poles are erected so that the finish will be free from the marks of handling, and the pole proper will seem to be monolithic with the base. After the surface has been sufficiently coated it is immediately trowelled to the desired lines, the aim being to secure a cement coating about 3/16 in. thick. The contract price for the finishing is $26 per pole.

companies and much more readily than municipally owned foreign companies, or that they had refused any reasonable petitions on the part of the public for extensions. One witness protested against the refusal of the companies to extend lines in his section, but ultimately he admitted he was an executive officer of a real estate development company.

The fourth claimed advantage is "increase of traffic due to lower fares and improved service." It is purely a speculation that any more people would be riding if fares were slightly or even materially reduced—a theory not based on available facts, testimony or evidence.

"Improvement in conditions of labor" is given as the fifth advantage. The testimony indicated that labor conditions on the street railways in the District were on a parity with other labor conditions in the District. If the conditions are unjust, the Public Utilities Commission and Congress should exhaust all possible means for an improvement before resorting to the financial hazard of municipal ownership.

"Full publicity of cost and value," the sixth advantage, should be obtained by the Public Utilities Commission. If that commission has not sufficient power, an appeal to Congress for further authority would surely be granted. Authoritative evidence was presented in the hearings to the effect that municipally owned utilities are more likely to err in this matter than privately owned public utilities.

"Change of purpose from private profit to public service" is given as the seventh advantage, but it is no advantage. Every improvement in service would be an advantage, but with equally good service from privately owned and publicly owned utilities it is a distinct disadvantage to close up an avenue of opportunity for American individual enterprise. A comparison of efficiency of employees of privately owned utilities with those of government offices will not be to the credit of the public employees.

PUBLIC OPINION IN THE DISTRICT

The report states that definite resolutions in favor of the Crosser bill were not submitted by any one of the score or more of citizens' organizations in the District. On the contrary, one presented resolutions against it and a number were reported as voting against going on record. Only fifteen witnesses appeared in behalf of the bill. The report contains a schedule showing the occupations of these witnesses, complaints against present operation, reasons for interest in bill, general arguments in favor of the bill, tax assessments, opinions concerning purchase regardless of cost and number of years in favor of municipal ownership. Of the fifteen witnesses, one complained against the present rate of fare, one against the number of cars running to the suburbs, two against crowds in rush hours and one against the refusal to build a suburban extension. The remainder of the witnesses either would not discuss this phase of the question or had no complaint to make. With one exception every witness expressed his firm belief in public ownership of public utilities as a general proposition, and a cross-examination as to the number of years they had been in favor of municipal ownership showed that the force behind the bill was almost all consistent and long-time advocates of municipal ownership.

The fifteen witnesses out of a total population of 350,000 represented a taxation assessment of $123,197 out of a total assessed valuation of $380,000,000 in the District. The above-mentioned tax assessment for the fifteen witnesses, however, was confined to four persons, the remaining eleven not being at all assessed. It is stated in general that efforts made by the committee to learn of any public demand for the Crosser bill were not successful other than in demonstrating that no public sentiment in favor of the bill existed.

MUNICIPAL OWNERSHIP IN GENERAL

In concluding, the minority report states that the evidence submitted has not been conclusive on the question of the success of municipal ownership of electric railways. Data from a 9-mile street railway in Monroe, La., were very scanty. A municipal line in New Orleans must be excluded from consideration, for it is merely a belt line for the transfer of freight from one terminal to another. As for the municipal line of San Francisco, when the annual redemption of bonds must be met, the net profits from operation would be inadequate to pay the costs of operation and all the other charges if the railway did not save $40,000 or more in taxes and services from other city departments. With this saving of $40,000, although at a like expense of other departments of the city, the lines may even then fail by a few thousands of dollars annually to meet all charges, on the basis of the present receipts and expenses. There appears to be no great inspiration for Washington in this example of municipal railways. James Dalrymple, general manager Glasgow Corporation Tramways, at one time expressed his opinion that municipal ownership of street railways should be successful in the United States, but after a visit to the United States and personal inquiry into American conditions he said: "What I have seen here, and I have studied the situation carefully, makes me realize that private ownership under proper conditions is far better for the citizens of American cities."

Ten Commandments of Safety

At the Lorain Steel Company's plant at Johnstown, Pa., the following ten commandments have been adopted for the guidance of the employees:

1. Thou shalt have no other thoughts than thy work.
2. Thou shalt take no unnecessary risks, nor try to show off, nor play practical jokes, for by thy carelessness thou mayest do injuries which will have effect unto the third and fourth generations to follow.
3. Thou shalt not swear, nor lose thy temper when things do not come just right.
4. Remember that thou art not the only one on the job and that other lives are just as important as thine own.
5. Honor thy job and thyself that thy days may be long in employment.
6. Thou shalt not clean machinery while it is in motion.
7. Thou shalt not watch thy neighbor's work, but attend to thine own.
8. Thou shalt not let the sleeves of thy shirt hang loose, nor the flaps of thy coat be unbuttoned, as they may get caught in the machinery.
9. Thou shalt not throw matches or greasy waste on the floor, nor scatter oil around the bearings, as a dirty worker is a clumsy worker, and a clumsy worker is a menace to his fellow workers.
10. Thou shalt not interfere with the switches, nor the dynamos, nor the cables, nor the engines, nor anything else thou art told is dangerous.

The Mayor of Portland, Ore., recently requested a committee composed of prominent men of Portland to investigate the general condition of the city and report to him with suggestions and recommendations to make Portland a safer city. B. F. Boynton, claim agent Portland Railway, Light & Power Company, was elected chairman.

Rolling Stock for Montreal Tunnel and Terminal

The Present Article Describes the Locomotives and Motor Cars for This 2400-Volt D.C. Electrification—The Locomotives Are Similar to the Butte Design but Are Geared for a Speed of 45 M.p.h..—The Motor Cars Are of Steel for Suburban High-Speed Service

BY W. C. LANCASTER, ELECTRICAL AND MECHANICAL ENGINEER MACKENZIE, MANN & COMPANY, LTD., MONTREAL

In the March 14 issue of the ELECTRIC RAILWAY JOURNAL the writer described the causes leading up to the choice of 2400 volts direct current for the electrification of the Canadian Northern Railroad at Montreal.

The electric rolling stock for the operation of the tunnel and terminal will consist of both electric locomotives for hauling the trains ordinarily operated by steam, and multiple unit cars to maintain a quick and frequent service between the main passenger terminal in the city and the country just west of Mount Royal, which, it is expected, will be rapidly built up and form one of the most attractive suburbs of Montreal.

LOCOMOTIVES

The 2400-volt d.c. locomotives are substantially the same in appearance and dimensions as those of the Butte, Anaconda & Pacific Railway, which were illustrated in the ELECTRIC RAILWAY JOURNAL for June 7, 1913, page 1010. As the schedule for the locomotive trains does not call for high speed, it was not thought necessary to resort to any of the special methods of connecting the motors to the driving axles, such as are used on the side-rod and gearless types. The motors will be nose-supported in the usual way and geared to the axle by means of twin gears.

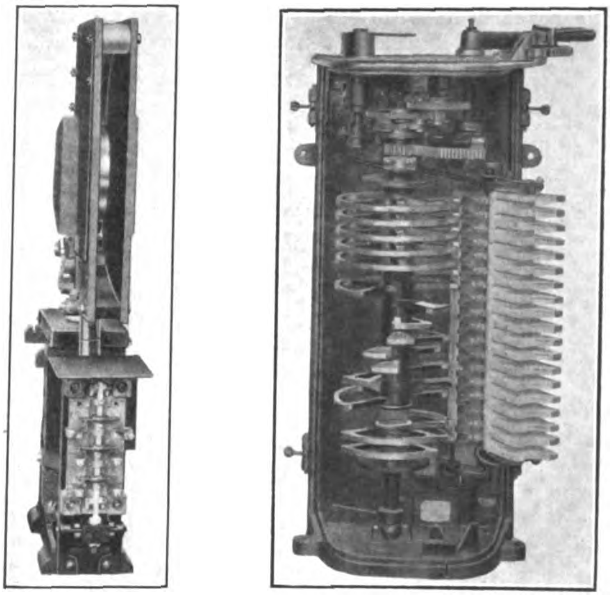
The locomotive has four axles with all the weight of the locomotive upon the eight driving wheels. The running gear consists of two four-wheel trucks, articulated together by a heavy hinge. The equalization of the trucks is accomplished by a semi-elliptic leaf spring over each journal box, connected through spring hangers to the frame and to the equalizer bars. The equivalent of a three-point suspension is thus obtained through the side equalization of one of the trucks and both side and cross equalization of the other truck.

The friction draft gear is mounted in the end frame casting of the truck. The cab, which is of the box type, is divided into three compartments, the center compartment for the apparatus and the two end compartments for the operator.. Each operator's compartment is supplied with controller, control switches, ammeter, air brake and pantograph control, air gages, 2400-volt cab heater, bell rope and control for the whistle and sanders, thus providing the locomotive with complete double-end control.

The motor equipment consists of four GE-229A commutating pole motors wound for 1200 volts and insulated for 2400 volts, two of these motors being permanently connected in series for operating on the 2400-volt trolley circuit. The one-hour rating of each motor is 315 hp at 1200 volts. The motors are designed for forced ventilation, which is obtained by means of a blower in the locomotive cab. Either pair of motors may be cut out, in case of emergency, by a special handle on the change-over switch. The locomotives are geared for a free running speed on tangent level track of approximately 45 m.p.h. and are operated as two-speed machines with ten points in series and nine points in series-parallel. The master controller used is of the non-automatic type and has two handles, one regulating the applied voltage at the motors and the other for controlling the direction of rotation of the motors. The rheostats which form the external motor resistance are placed near the roof of the cab and provided with ample natural ventilation.

The master controller and contactor energizing circuits are designed for 125 volts. Each contactor is easily accessible without any disturbance to adjacent contactors. A special electro-pneumatic change-over switch is used for making the transition between series and series-parallel connection of the pairs of motors.

The 125-volt current for operating the contactors and for lighting the cab and headlights is obtained from a motor-generator set, the motor of which has two 1200-volt windings and two 1200-volt commutators in series for operation on 2400 volts. This set is mounted in the center cab and also drives the blower for providing forced ventilation to the main motors.



MONTREAL TERMINAL ELECTRIFICATION—CONTACTOR WITH INTERLOCK; MASTER CONTROLLER FOR LOCOMOTIVE

Fuses of the copper ribbon type placed in fuse boxes provide protection for each individual circuit as well as the main circuit from the trolley. These fuse boxes are all arranged to blow into a common chamber designed to take care of the arc. In addition to the fuse on the main circuit, a main switch is also provided. This is of the knife-blade type, being opened and closed by a handle placed in a position for easy operation in case of emergency or when it might be necessary to open the circuit while carrying current. This main switch blows into the chamber provided for the fuses, and has a powerful magnetic blowout.

The trolleys are of the Butte roller pantograph type, pneumatically operated and mounted on insulated bases. Two pantographs are used per locomotive. A hand pump is provided in case a locomotive has been standing for some time and has no air supply.

A Warner speedometer, similar to the type largely used on automobiles but especially designed for locomotives, is located in each operating cab. These will

be connected to the driving wheels of the locomotive by means of flexible shafts and gearing.

A combined straight and automatic air-brake equipment is provided on each locomotive. This equipment includes a 2400-volt motor-driven air compressor, the set consisting of two 1200-volt motors operating in series on 2400 volts and direct-connected to an air compressor having a displacement of 100 cu. ft. of free air per minute. The approximate total weight of each locomotive is 83 tons. Some of its principal dimensions and characteristics are given in the following table:

Length inside knuckles	37 ft. 4 in.
Length over cab	31 ft. 0 in.
Overall height, pantograph down	15 ft. 6 in.
Height over cab	12 ft. 10 in.
Over-all width	10 ft. 0 in.
Total wheelbase	26 ft. 0 in.
Rigid wheelbase	8 ft. 8 in.
Total weight, all on drivers	83 tons
Wheel diameter	46 in.
Tractive effort at 30 per cent tractive coefficient	49,800 lb.
Tractive effort at one-hour rating	20,300 lb.
Tractive effort at continuous rating	14,500 lb.

A floor plan of the cars, showing the arrangement of seats, doors and windows, is published. No sliding doors are used, as such doors tend to weaken the car just where most strength is required in case of collision. All the doors swing, so that the corners of the cars may be made as strong as is necessary.

Cross seats are used near the center of the car and longitudinal seats near the ends. This arrangement gives plenty of room near the doors where most of the crowding occurs when passengers are leaving or entering. It also tempts the passenger by means of the more comfortable cross seats to "move up to the center of the car." As shown in the side and end views of the car, presented herewith, the underframing is entirely of steel. The car body is also of steel except for window frames, wainscoting, side posts and part of the floor, which are of wood, and the headlining, which is of a heat-resisting, pressed-fiber board.

The underframing is of the center box girder construction, employing two 9-in. 15-lb. channels spaced

16¾ in. back to back and fitted with a top cover plate 26 in. x ¼ in. and a main bottom cover plate 24 in. x ⅜ in. The body and end sills are of structural steel shapes. Trap doors of Edwards all-steel construction are installed. The bolsters are built up of plates and angles. The Standard Coupler Company's buffers and Miner draft gear are used.

The flooring consists of a bottom layer of tongue and grooved spruce, on top of which is spread a layer of three-ply "Salamander." Between this and the main floor is an intermediate insulating floor formed of ⅛ in. steel plate, on top of which is also laid a layer of three-ply "Salamander." The main steel floor, on top of which is spread a layer of "Flexotile" composition flooring, consists of "Chanarch" steel.

As regards the side framing, the main side posts are formed of 3 in. x 2 in. x 5/16 in. rolled steel angles acting as a stiffener for the side sheeting and a suitable connection for the wooden side posts. At the belt rail the sheeting is further stiffened by a 4-in. x ½ in. bar extending the full length of the body. The corner posts are built up of 3-in. x 2-in. angles with 3/16-in. pressed steel cover plate extending around and over the side and end sheets. The side sheets are of 0.110-in. thick cold rolled steel plate.

MONTREAL TERMINAL ELECTRIFICATION—CROSS-SECTIONS SHOWING FLOORING, HEAT INSULATION, ETC.

Particular attention has been given to the heat insulation. For the sides, roof and ends of the car this insulation consists of three-ply "Salamander." It is secured to the steel by means of glue and the Cleveland Tack Company's "Clinchtite" nails spot-welded to the sheet steel and provided with steel retaining bands. This method is similar to that used by the New York, Westchester & Boston Railway.

The trucks are of this railroad's plate frame construction built for a center plate capacity of 40,000 lb., and they are of the side equalized type. Case-hardening is applied for all hangers and rod jaws, for all pin ends of levers and where all holes occur in the same. The

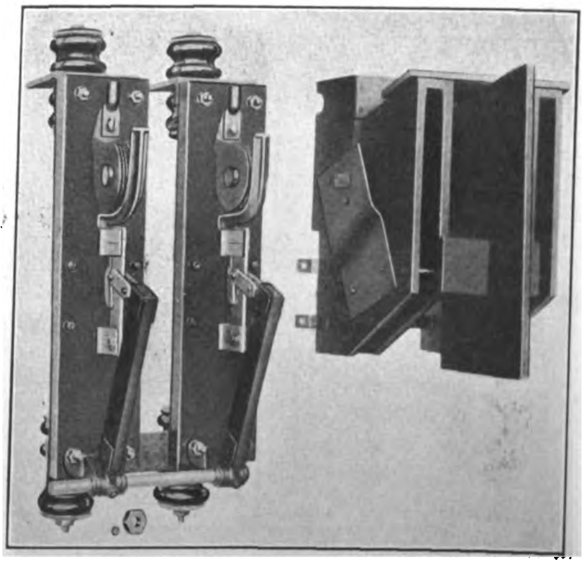
MONTREAL TERMINAL ELECTRIFICATION — TRUCK FOR MOTOR CARS



MONTREAL TERMINAL ELECTRIFICATION—MAIN SWITCH wheels are of rolled steel and are 36 in. in diameter. The journals are 5½ in. x 10 in. and of the American Electric Railway Association standard with McCord boxes.

The outside and inside finish and all fittings and other details are made to conform as nearly as possible with Canadian Northern standard practice.

The principal dimensions are given in the following table:

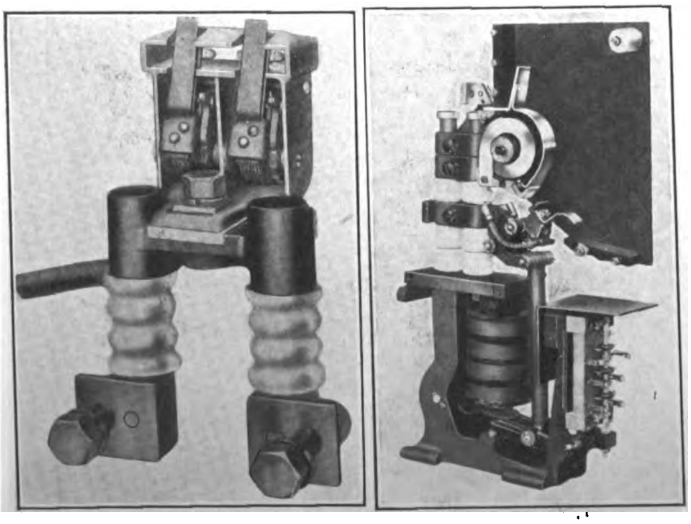
Length over buffers	67 ft.	5¾ in.
Length over body corner posts	57 ft.	6¼ in.
Truck centers	42 ft.	9 in.
Width over side sill angles	9 ft.	10½ in.
Width over eaves	10 ft.	2¾ in.
Height top of rail over roof	13 ft.	0 in.
Height top of rail to underside of side sill	3 ft.	7½ in.
Center to center of body side bearings	4 ft.	10 in.
Center to center deck sills	5 ft.	6 in.

The approximate weight of the car loaded and equipped is 160,000 lb.

The electric hot air system of car heating is used. One complete heater is placed underneath each car and receives its energy direct from the 2400-volt supply. The heater has a capacity of approximately 25 kw and is constructed for two heat combinations so as to provide for the changes in temperature conveniently and economically.

The complete heating equipment consists of the heating unit, blower and regulating mechanism, the controlling switch and thermostat of the regulating mechanism being arranged for operation from the 600-volt supply. Air is forced over the heating unit by means of the blower and distributed to the car through the air ducts along the sides of the car. The blower used for the circulation of the air is operated by a motor which is connected in series with the heating unit on the ground side. The capacity of the blower is approximately 1000 cu. ft. of air per minute.

The motor equipment consists of four fully ventilated GE-239A, 125-hp, 1200-volt commutating pole motors insulated for 2400 volts. Two of these motors are permanently connected in series for 2400-volt operation. Ventilation of the motor is accomplished by drawing air into the armature at the pinion end by means of the fan on the armature shaft. The air passes longitudinally through the whole interior of the motor and is expelled through an opening in the frame at the commutator end. This opening is protected by wire mesh. A back view of the brush-holder and support is also shown.



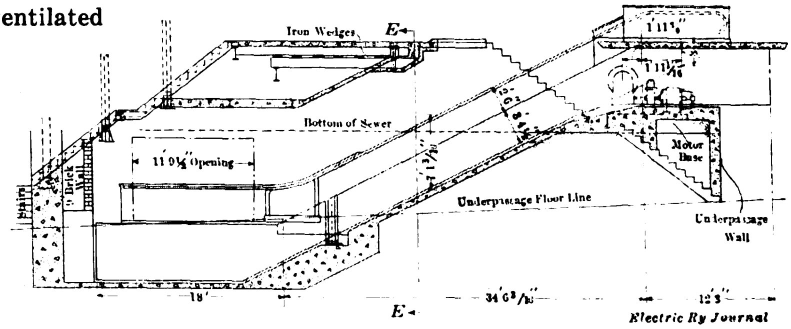
MONTREAL TERMINAL ELECTRIFICATION—REAR OF BRUSH-HOLDER; SIDE VIEW OF CONTACTOR WITH INTERLOCK

The control is of the non-automatic type for multiple-unit operation. The equipment includes a motor-generator set for furnishing 600-volt current for the control circuits, the air compressor and lighting circuits. This set consists of two 1200-volt motors, operating in series on 2400 volts, direct connected to a 600-volt generator. The master controller, contactors, switches, reverser and pantograph are of essentially the same construction and appearance as those already described for the locomotives. The controller will have five steps in series and four steps in parallel. It differs from the locomotive controller in having the usual motorman's operating handle instead of a lever. This handle is provided with means for cutting off power and applying air brakes in case the motorman removes his hand.

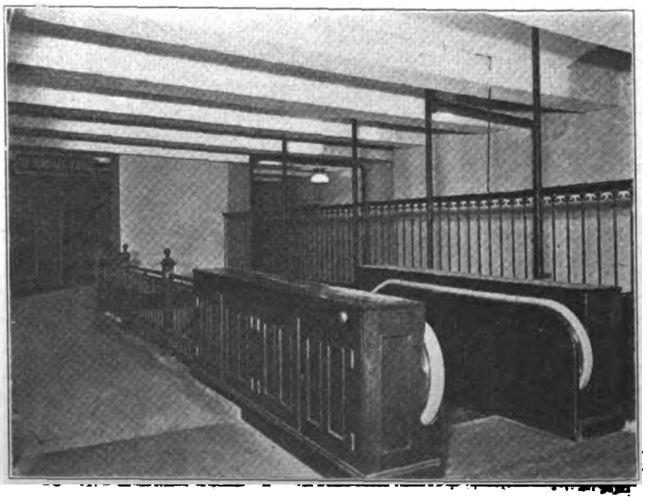
Copper ribbon fuses similar to those on the locomotive will be used and an aluminum cell lightning arrester is installed on each car.

Improvements at the Juniper Street Station in the Philadelphia Subway

In the Market Street subway in Philadelphia there is a point near the business center where the east-bound surface cars in the subway make a loop under the elevated line cars, which are also in the subway, and return west. Passengers coming in from West Philadelphia transfer at this point if they desire to go farther east, say to the Delaware River ferries. Obviously a considerable part of the traffic terminates at this station, Juniper Street. This underground station has been laid out with a view to making its operation so convenient for passengers that there could be no possible cause for complaint on account of the necessity for using two levels. For this reason a down escalator has been installed between the two levels, in addition

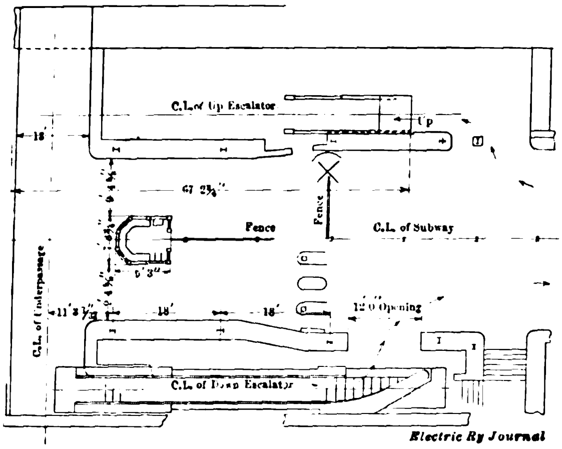


PHILADELPHIA SUBWAY—CROSS-SECTION ESCALATOR WAY, JUNIPER STREET STATION



PHILADELPHIA SUBWAY—VIEW OF ENTRANCE TO DOWN ESCALATOR to the up escalator and conveniently placed staircases. The down escalator is very popular in spite of its comparative novelty, very few passengers using the stairway, which they could do with little extra effort.

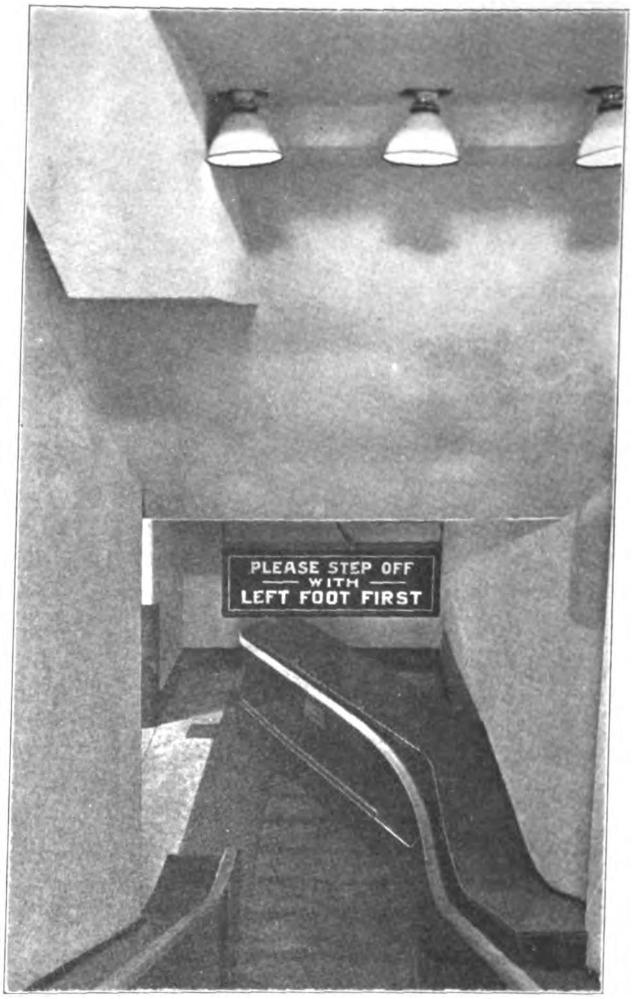
The accompanying illustrations show some details of the station. One diagram is a plan of the lower level. Passengers entering the lower level direct from the street come in at the left in the figure, secure tickets at the booth shown and pass through the entrance to the large passage at the right which leads to the surface car loading platforms. Outgoing passengers from the lower level can pass out through the turnstile or to the upper level on the up escalator. Passengers from the upper level can reach the lower level either by way of the down escalator or by the stairs directly over it. A section showing the down escalator and staircase is given in a second diagram.



PHILADELPHIA SUBWAY—PLAN OF LOWER LEVEL, JUNIPER STREET STATION

The halftones show details of the down escalator, those from photographs taken at the foot having been chosen to illustrate particularly the method of lighting used. Unusually good light is desirable at this point to avoid confusion due to the novelty of the construction. The escalator way is brilliantly illuminated by lamps mounted in reflectors near the ceiling beams and through openings in the bottom of the illuminated box sign. An usher is located at the bottom of the escalator to assist passengers who may still not understand the method of getting off.

PHILADELPHIA SUBWAY—FOOT OF ESCALATOR, LOOKING UP



PHILADELPHIA SUBWAY—FOOT OF ESCALATOR, LOOKING DOWN, SHOWING ILLUMINATED SIGN

The Juniper Street station involved special structural problems due to the difficulty of underpinning the adjacent buildings. Cross beams much heavier than were needed for floor support were used for this purpose. Space limitations also prescribed a most economical arrangement of staircases, escalators and passageways. The result has been a layout which permits the handling of large crowds with little congestion.

The city of San Francisco is using the cement gun to finish the ornamental concrete poles which are being erected on Van Ness Avenue in San Francisco. The poles are for the double purpose of lighting and carrying trolley wires for the new municipal railway, and the coating is being applied after the poles are erected so that the finish will be free from the marks of handling, and the pole proper will seem to be monolithic with the base. After the surface has been sufficiently coated it is immediately trowelled to the desired lines, the aim being to secure a cement coating about 3/16 in. thick. The contract price for the finishing is $26 per pole.

Proceedings of Pacific Claim Agents' Association Convention

At the opening session of the Pacific Claim Agents' Association convention in Spokane, Wash., on July 8-11, addresses were delivered by W. J. Hindley, Mayor of Spokane, and D. L. Huntington, president Washington Water Power Company, Spokane, Wash. Most of the addresses, papers and discussions making up the program were related to two general questions; namely, protection against fraudulent (personal injury) accident claims, and the "safety first" movement. After the annual address by J. H. Handlon, president of the association, papers were read by A. M. Lee, Harrison Allen, S. A. Bishop, J. H. Handlon, H. G. Winsor, Thomas G. Aston, B. F. Boynton, A. E. Beck, H. K. Relf, George Carson, T. M. Lyall, Ida P. Newell and T. J. Rupli. The papers by Messrs. Bishop, Handlon, Boynton, Allen and Carson were abstracted in the ELECTRIC RAILWAY JOURNAL of July 18 and that by Mr. Relf in the ELECTRIC RAILWAY JOURNAL of July 25. An abstract of the paper read by Mr. Winsor is published below.

The last day's session was opened with an address by Charles T. Banks, superintendent of efficiency of the Northern Pacific Railway, St. Paul, Minn., who outlined the safety measures and safety organization of his company. The final paper was the report of the association's standing committee on safety, composed of Messrs. Carson, Aston, Lee, Boynton, Beck and Winsor. This report was abstracted in the ELECTRIC RAILWAY JOURNAL of July 25. The convention had as invited guests Chairman Floyd L. Daggett and Clarence Parker, of the State Industrial Insurance Commission, both of whom addressed the convention and participated in the discussions.

Officers of the association for the ensuing year were elected as follows: President, A. M. Lee, Seattle, Wash.; first vice-president, Thomas G. Aston, Spokane, Wash.; second vice-president, H. K. Relf, Portland, Ore.; third vice-president, S. A. Bishop, Los Angeles, Cal., and secretary-treasurer, T. N. Henry, Seattle, Wash. The executive committee members were chosen as follows: H. G. Winsor, Tacoma, Wash.; Thomas A. Cole, Los Angeles, Cal.; A. E. Beck, Vancouver, B. C.; A. Molesworth, Portland, Ore.; L. Frank Gordon, Portland, Ore., and T. J. Rupli, Seattle, Wash.

PACIFIC CLAIM AGENTS' INDEX BUREAU

The annual meeting of the board of directors and the officers of the Pacific Claim Agents' Index Bureau was held in Spokane, Wash., July 11, the last day of the Pacific Claim Agents' Association convention. Since the beginning of 1912 this bureau has accumulated in its card index files more than 25,000 names of personal injury claimants and exposed more than 200 "repeaters." Officers were elected for this year as follows: President, George Carson, Seattle, Wash.; first vice-president, B. F. Boynton, Portland, Ore.; second vice-president, J. S. Mills, Oakland, Cal.; treasurer, H. G. Winsor, Tacoma, Wash., and secretary, T. N. Henry, Seattle, Wash. The board of directors is composed of Thomas G. Aston, Spokane, Wash.; L. Frank Gordon, Portland, Ore.; A. E. Beck, Vancouver, B. C.; Thomas A. Cole, Los Angeles, Cal.; H. K. Relf, Portland, Ore., and H. J. Handlon, San Francisco, Cal.

ACCIDENT COST OF TRAINMEN AND LENGTH OF SERVICE

Following is an abstract of the paper "Accident Cost of Trainmen and Length of Service," by H. G. Winsor, claim agent Tacoma Railway & Power Company, Tacoma, Wash.

In making an investigation of step and gate accidents during the latter part of 1913 it developed that a large percentage of such accidents could be traced to trainmen who had been in the service for a certain period. In presenting the data now it must be noted that no information has been sought outside of the properties represented by the writer, and it may be possible that the results shown may be materially changed regarding a company located in a different region and operating under different circumstances.

The properties which the writer represents consist of: first, the Puget Sound Electric Railway, an interurban line operating between Tacoma and Seattle, and between Tacoma and Puyallup, Wash., having a total trackage of 97.84 miles and operating seventy-six trains daily; second, the Tacoma Railway & Power Company, operating eighty-three regular cars over 64.86 miles of track and termed the "city lines"; and, third, the Pacific Traction Company, an urban line from Tacoma to the Lake District, operating six cars over 22.13 miles of track. As the physical conditions under which each of these companies operates are materially different, it has been thought advisable to present the figures of each company separately.

The Puget Sound Electric Railway employs sixty-six regular men in the passenger service. During the year 1913 the total car miles amounted to 1,390,095; the total number of passengers carried, 2,693,085, and the accident cost charged to trainmen, $0.0248 per car mile and $0.0128 per passenger carried. The percentages of medical, legal, miscellaneous and settlement costs for 1913, charged to trainmen according to their years in service, are shown in Table I.

TABLE I—SHOWING PERCENTAGES OF 1913 ACCIDENT COSTS FOR PUGET SOUND ELECTRIC RAILWAY TRAINMEN ACCORDING TO YEARS IN SERVICE.

Length of Service	Percentage Men in Service	Per Cent	Settlements	Medical	Legal	General
Less than six months...	10.6	8.5	$2,607	$284	$53	$17
Six months to one year.	30.3	28.6	8,689	947	89	56
One year to two years..	18.2	20.0	6,083	663	18	39
Two years to three years	9.1	14.3	4,345	474	160	28
Three years to five years	9.1	2.9	869	95	178	6
Five years and more....	22.7	25.7	7,820	853	125	50
	100.0	100.0	$30,413	$3,316	$623	$196

The Tacoma Railway & Power Company employs 294 platform men in regular service. These men operate cars over the city lines, which include a cable line of 1.58 miles. All cars are equipped with gates. During the year 1913 the total car miles amounted to 3,643,858; the passengers carried, 25,737,670, and the accident cost charged to trainmen, $0.0150 per car mile and $0.0021 per passenger carried. The percentages of medical, legal, miscellaneous and settlement costs for the trainmen of the Tacoma Railway & Power Company according to their years of service are presented in Table II.

TABLE II—SHOWING PERCENTAGES OF 1913 ACCIDENT COSTS FOR TACOMA RAILWAY & POWER COMPANY TRAINMEN ACCORDING TO YEARS IN SERVICE.

Length of Service	Percentage Men in Service	Per Cent	Settlements	Medical	Legal	General
Less than six months...	32.6	21.38	$10,634	$497	$461	$60
Six months to one year.	11.9	17.92	8,910	416	386	50
One to two years......	10.6	17.92	8,910	416	386	50
Two to three years.....	14.4	11.56	5,748	269	249	33
Three to five years.....	11.3	17.92	8,910	416	386	50
Five years and more...	19.2	13.30	6,611	309	286	38
	100.0	100.00	$49,723	$2,323	$2,154	$281

The Pacific Traction Company employs eighteen men in the regular service, operating five cars. Approximately 75 per cent of the 22 miles of track is laid on private right-of-way. The cars are equipped with doors and the greater part of the line is protected by block signals. The total mileage for the year 1913 was 505,881; the total number of passengers carried, 1,886,884, and the cost of accidents charged to trainmen, $0.0032 per car mile and $0.00086 per passenger carried. Table III gives the percentages of medical, legal, miscellaneous and settlement costs for the trainmen of the Pacific Traction Company according to their years of service.

TABLE III—SHOWING PERCENTAGES OF 1913 ACCIDENT COSTS FOR PACIFIC TRACTION COMPANY EMPLOYEES ACCORDING TO YEARS IN SERVICE.

Length of Service	Percentage Men in Service	Per Cent	Settlements	Medical	Legal	General
Less than six months...	5.6	7.1	$90	$3	$14	$8
Six months to one year.	5.6	7.1	90	3	14	8
One to two years......	22.2	28.7	360	13	59	30
Two to three years.....	11.1	...	...	...	...	...
Three to five years.....	11.1	...	...	...	...	...
Five years and over....	44.4	57.1	718	26	117	60
	100.0	100.0	$1,258	$45	$204	$106

In the investigation necessary to compile these figures, a careful observance of the cause of each accident was made. The personality and experience of trainmen who were responsible were also carefully considered, as well as the difference in physical conditions of the several lines. Another matter of considerable importance was the attitude of the public in different sections of the territory served.

Conditions which are present in Tacoma may be entirely different in some other locality. For this reason the writer has not thought it wise to report his conclusions as to what period of the average trainmen's service is the most efficient with respect to the elimination of accident cost. It may be said, however, that with the average trainmen there is a certain period of inexperience which adds greatly to a company's troubles. Yet after he has been in the service for a certain period, he is quite likely to assume responsibilities which belong to someone else and thus unnecessarily take chances which may ultimately result in serious accidents.

Safety Committee Meeting in Memphis

The first meeting of the July to December safety committee of the Memphis Street Railway Company was held July 11, the meeting being notable for the interest shown by the new members. Figures were read showing marked progress in the "safety first" work, and a paper entitled "Courtesy," was presented by A. D. McWhorter, master mechanic. This follows in abstract form:

The men who represent this company in its transportation department are selected with a view of establishing two important rules—caution and courtesy. Coming in direct personal contact with the public, the company's only customers, motormen and conductors are in a position to work for the permanent good or the incalculable harm of the company, and the reward for good or bad service is certain. The street car traveling public is composed of many peculiar individuals, and nobody knows better than the platform men how difficult it is to deal with that same public and keep its individual members in a contented frame of mind. It can be done, however, and, as a man can learn to handle the traveling public so can he learn to handle bigger men and bigger things. Sincerity, courtesy and, above all, common sense are the qualities necessary.

Getting along with the public is a great gift. The man with a small mind has a tendency to pick flaws, to argue, to find fault. Instead of dropping a misunderstanding he insists on "having it out." The man with the large mind rides over these little annoyances—the petty things over which the small man trips and stumbles. A conductor is not merely a collector of fares; he is the personal representative of the company. The student of human nature knows that tact is a great producer of success and that genius without tact is about as valuable as an expired transfer. It is not necessary to use a club of sarcasm or a battering ram of argument to gain a point with a passenger who may be full of friction, or at cross purposes with the world. It pays always to be patient with men and mules.

The person who is polite often finds himself imposed upon. He opens a door to let an old lady pass. He soon finds not only the old lady but everybody else takes advantage of the open door, never pausing to utter a word of thanks but absolutely blocking the door for the polite person himself. But he who conquers himself conquers the world. Courtesy is almost an absolute necessity for success in business and the men possesed of good manners, other things being equal, have reached fame or higher positions, when men more industrious as well as more scholarly, but wanting attractive manners, have remained in obscurity. Like virtue, politeness is its own reward. A pleasant manner helps to make the wheels of life run more smoothly and a little tact and a bit of kindness clear up many a difficulty, leveling many a rough way and shedding over the gray horizon of every-day life a ray of sunshine and joy.

The next speaker was E. W. Ford, general superintendent, who made a "chalk talk" on miles run per accident during the month of June, showing comparison with the same month of last year. The figures read by Mr. Ford showed the work in a healthy condition, showing a 30 per cent decrease in accidents over last year with a corresponding increase in number of miles run per accident.

Attorney Roane Warring spoke on the responsibility on the members of the safety committee, stating that the committee was now organized, the interest in the movement was increasing and each outgoing committee was showing a larger reduction in accidents than the previous committee. While the members should realize that they could help the other employees prevent accidents by reporting violations of rules, carelessness, unsafe operation, defective equipment, etc., they should be cautioned against looking on the safety movement as being for the purpose of spying on fellow workmen. It was for the mutual good of the employee and employer to help each other and prevent accidents. In conclusion Mr. Warring called particular attention to the humane side of the safety movement, saying that preventing accidents meant preventing untold sorrow, suffering, untold pain and loss of life which grow out of accidents. Attorney L. P. Miles also spoke.

District of Columbia Public Utilities Commission Report

The Public Utilities Commission of the District of Columbia has issued a report of its official proceedings for the ten months ended Dec. 31, 1913. The report contains information relative to electric railway accidents, inspections, equipment, extensions, pavement construction costs, service and track conditions. In addition to the foregoing there are presented tables showing the assets and liabilities of the companies within the district, the cost of road equipment and general expenditures, outstanding securities, operating revenues and expenses, analysis of passengers carried and miles of road and number of cars operated. In connection with each electric railway the commission also gives the results of its investigation concerning the outstanding stocks, bonds and debentures as of March 4, 1913. The information on these subjects, which was secured by means of answers to very detailed questions, is practically complete in regard to the companies' capitalization and ownership.

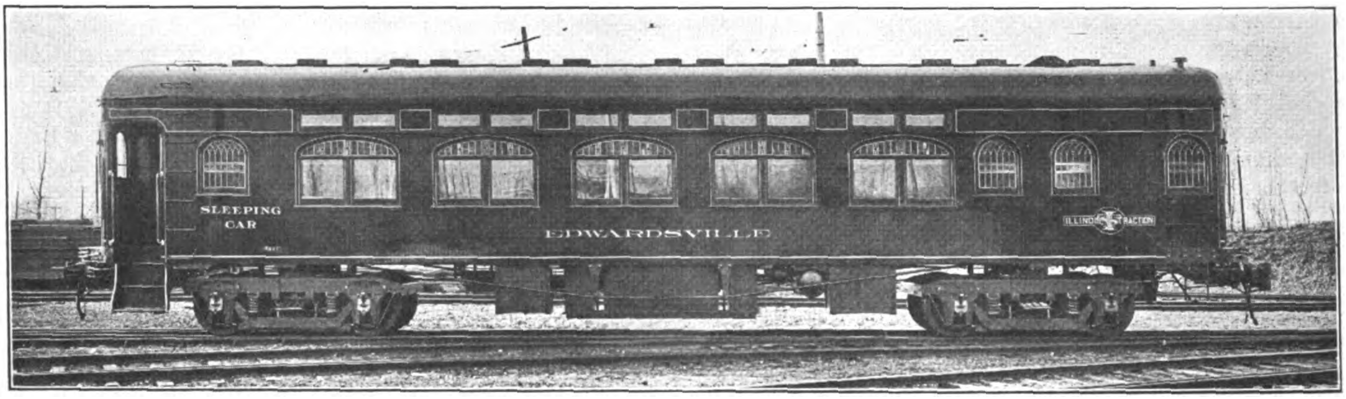
Illinois Traction System Special Service

Experience of Past Few Years Has Been Utilized in Devising Improvements in Details Making Electric Sleeper Service Very Attractive—Energy Consumption per Ton-Mile with Trail Cars Is Reasonable

The Illinois Traction System has operated sleeping cars for more than six years and observation parlor cars for nearly three years.

The original electric railway sleeping cars were built by the Holland Sleeping Car Company. These cars were inferior in their accommodation compared with later types of sleeping cars, but their use proved to the management that sleeping car service was a commercial possibility for an electric railway. After the Holland cars had been operated less than two years, four large sleeping cars incorporating many novelties in car-building, all designed to make sleeping-car service more comfortable and more safe were built especially for service between St. Louis, Springfield and Peoria.

H. E. Chubbuck, vice-president executive, and J. M. Bosenbury, superintendent of motive power, and equipment, Illinois Traction System, were the joint inventors of many of the novel features such as folding berths, safety deposit boxes for valuables, windows in upper berths, etc. The St. Louis Car Company has just completed another sleeper built according to the Illinois Traction standards. The new car is illustrated herewith. It is the fifth one of the new type to be built, and all five are now in active service. This type of car was described and illustrated on page 522 of the Electric Railway Journal for Sept. 30, 1911.



ILLINOIS TRACTION SYSTEM—NEW SLEEPING CAR

The sleeping cars, and in fact all of the freight and passenger cars of the Illinois Traction System, conform to the safety appliances and M.C.B. interchange requirements.

The sleeping cars are 57 ft. long over bumpers and 9 ft. 7 in. wide, and weigh 84,000 lb. The bodies are of heavy substantial Pullman-type construction with segmental arch roofs. They are mounted on steam-coach type four-wheel steel-frame trucks with quadruple elliptic bolster springs, and are provided with the M.C.B. contour, high-knuckle Sharon couplers, manufactured by the National Malleable Castings Company. These couplers are standard for all of the interurban equipment of the Illinois Traction System. There are twenty berths in each car, and the design of upper and lower berth is uniform. The cars are illuminated by seventy Mazda lamps, fed from a special panel governing a Gould storage battery of sixteen cells.

Sleeping-Car Service

Sleeping-car service is given between Peoria, Springfield and St. Louis. The distance from St. Louis north to Springfield is 100 miles, and from there to Peoria 75 miles.

The Illinois Traction System is the only road offering St. Louis, Springfield, Peoria sleeper service. The northbound train leaves St. Louis daily at 11:45 p. m., arrives at Springfield at 4:10 a. m. and Peoria at 7 a. m. The southbound train leaving Peoria 11:30 p. m., arrives at Springfield at 2:25 a. m. and St. Louis at 7:05 a. m. These trains are made up of a combination express, passenger motor car, a trailer coach and the sleeping cars. South of Springfield, the trains in both directions have two sleeping cars, namely, the through car between Peoria and St. Louis and the set-off Springfield car. The sleeping cars are ready for occupancy at 10 p. m., and passengers are allowed to remain in them until 8 a. m.

The combination motor-express cars which haul the sleeping-car trains were described in the Electric Railway Journal for Feb. 2, 1911, page 275. These cars are 52 ft. 6 in. long, 9 ft. 5⅜ in. wide, have underframing and body of heavy design and have four 140-hp motors. These motor cars satisfactorily haul the trailer coach and two or three sleeping cars at the average schedule speed of about 23 m.p.h., which includes time for cutting in and out extra cars at Springfield and making all station stops between 6 and 7 a. m. as the terminals are approached. The motor cars weigh about 100,000 lb. each. All sleeping car trains are equipped with Westinghouse A. M. V. air brakes with universal valves in place of triple valves.

Originally the sleeping-car trains were made up of a combination motor-passenger and baggage coach and two sleeping cars. The combination motor coach has seats for but twenty-four passengers, but these trains have developed coach traffic to such an extent that trailer coaches are now required. The baggage compartment of an ordinary motor passenger coach is not large enough to handle all of the baggage and express required for the sleeping-car trains. Considerable excess seating capacity also is desirable because of unexpected parties which use the trains for rides of 40 or 50 miles out of the terminals.

The sleeping car trains handle considerable theater traffic and serve as an "owl" train for the middle section of the road and as an early morning train for the other section near the arriving terminals.

A train crew for a four-car train is made up of a motorman, conductor, brakeman and two sleeping-car porters. The porters are paid $45 a month and perform duties similar to those of Pullman-car porters.

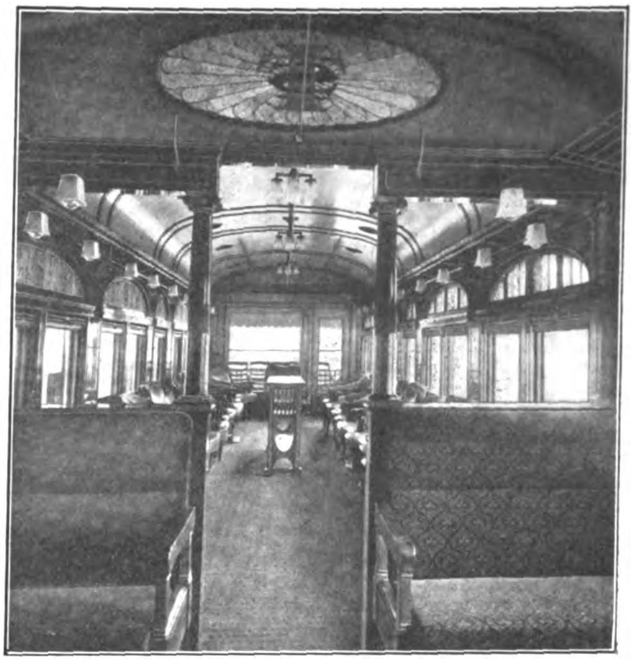
The sleeping-car trains have brought to this railway system traffic which it otherwise would not have had. Practically all of the passengers who now take the sleeping-car trains, both in the coaches and in the sleepers, would otherwise have taken steam trains had the Illinois Traction System not introduced the sleeping-car service. The business has gradually increased until now five sleeping cars are required, four of which are in operation daily and a fifth in reserve for overhauling and for special parties, to which latter use it is frequently put. One reason for the success of this service is that passengers can go to bed in the sleeper at one terminal and be at the other at 7 o'clock in the morning for an expenditure less than the cost of a hotel room in Springfield. The berth fare between Peoria and St. Louis is $1.50 for a lower and $1.25 for an upper.

The sleeping-car trains have net earnings of about $40,000 a year, and it is interesting to note that the earnings are practically the same for summer and winter. The gross earnings of a typical month were $5,679, the expenses $2,425 and the net profit $3,254. In these expenses are included the wages of motorman, conductor and porters, superintendence, power, maintenance of equipment, trackage, laundry, advertising, car cleaning, etc. The cost for laundry is about $15 per month per car, not including wear and tear.

PARLOR-OBSERVATION CARS

In 1911 the Illinois Traction System inaugurated an extensive parlor observation car service which has since been expanded, until now seven fine, large, heavy parlor cars are in use. The latest addition to this equipment is illustrated herewith. This car conforms to the earlier standard and was built by the St. Louis Car Company. The designs for this car, as well as those for the sleeping cars, were made and the construction supervised by Mr. Bosenbury. The parlor car weighs 80,000 lb.

Parlor cars are attached to limited trains, but not all limited trains have parlor cars. Those with the parlor cars attached make two round trips a day between Peoria and St. Louis, 175 miles each way, one round trip between Springfield and St. Louis, 100 miles each way, and two round trips between Springfield and Danville, 127 miles each way. The Danville-Springfield service connects with the Peoria-Springfield service, so that through service is given to and from St. Louis. The running time of a limited passenger motor car with trailer attached from St. Louis to Danville, 227 miles, is nine hours and fifteen minutes, and the running time between St. Louis and Peoria is six hours and forty-five minutes. Thus the schedule speeds of these trains are about 25 m.p.h., including all stops and dead time at junctions.



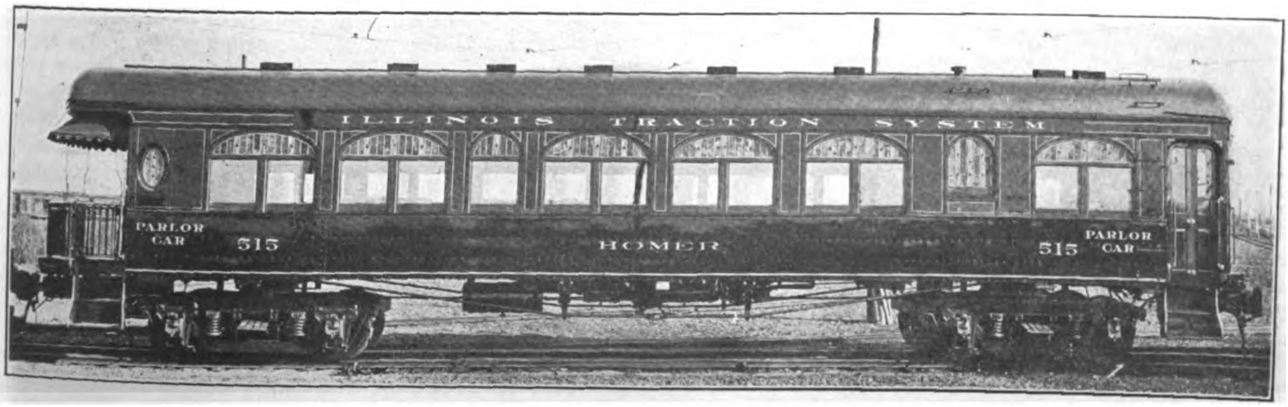
ILLINOIS TRACTION SYSTEM—INTERIOR OF PARLOR-OBSERVATION CAR

The parlor cars are added to the limited trains which regularly carry the most through business. In this way the normal electric railway load has better equipment, and inducements are offered which have resulted in building up traffic that formerly made the long runs on the trains of parallel steam railroads.

These parlor observation cars are 57 ft. long, 9 ft. 7⅛ in. wide, are mounted on standard steam-coach steel-frame four-wheel trucks with quadruple elliptic bolster springs, and are equipped with the Sharon type M.C.B. coupler. An interior view of the parlor car is shown. There are eight double seats, twenty-two mahogany chairs and six Pullman type camp stools.

The rates for seats in the parlor cars are approximately ½ cent per mile in addition to regular first-class fare. A minimum rate of 15 cents is observed. All station agents sell seat tickets and make reservations in advance for parlor car seats and sleeping-car berths.

The energy consumption of these limited trains with heavy observation parlor-car trailers, as compared with the same limited motor cars, shows that while the motor car alone consumes about 64 watt-hours per ton mile the same motor car, when hauling the parlor car as a trailer in the same run, consumes about 46 watt-hours per train ton mile.



ILLINOIS TRACTION SYSTEM—PARLOR-OBSERVATION TRAIL CAR

COMMUNICATIONS

Resistance to Car Motion

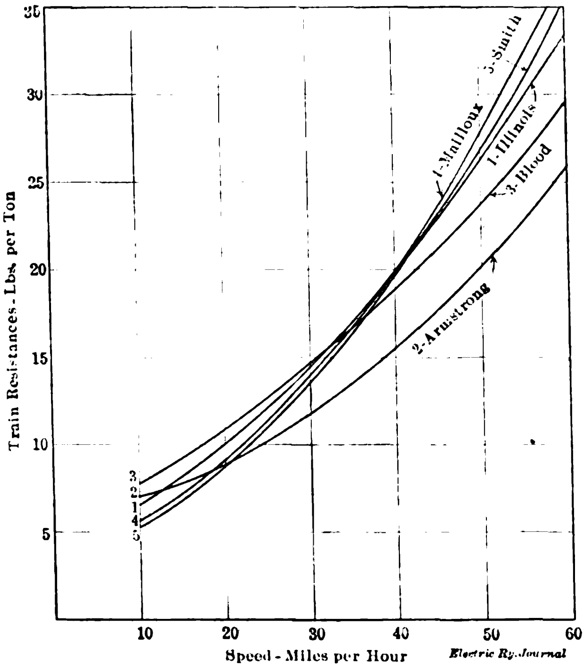
PURDUE UNIVERSITY
LAFAYETTE, IND., Aug. 5, 1914.

To the Editors:

I have read with interest the abstract of the University of Illinois Bulletin on train resistance, published in the issue of the ELECTRIC RAILWAY JOURNAL for June 20, and the comments by C. O. Mailloux and Louis Bell, in the issue for July 11. Railway engineers are again indebted to the University of Illinois Experiment Station for some valuable experimental work in train resistance measurement.

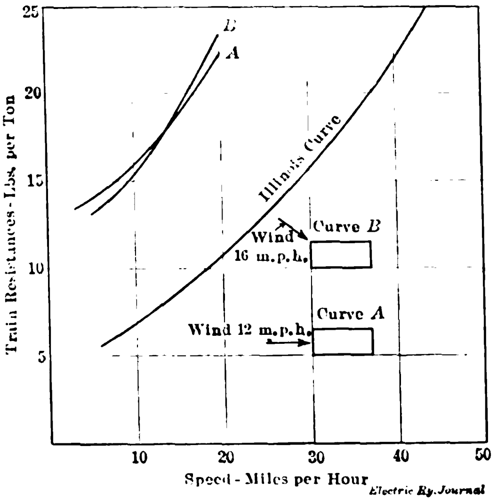
In the measurement of train resistance so many variable conditions are encountered that it is extremely difficult to secure consistent results. The variation in results obtained for a given speed with apparently similar car and track conditions are well illustrated by the illustration accompanying the abstract which shows the results for a typical individual test. I therefore agree with Mr. Mailloux, in his statement that the coefficients of the second and third terms of the Illinois formula indicate a degree of precision which is difficult of attainment in train-resistance measurements. The method used in making the resistance measurements has possibly as few objections as any in use, but any method involving the use of the difference of two quantities of which one at least cannot be measured with a great deal of precision is hardly ideal. I fear, however, that we shall have as much trouble in learning how to measure train resistance by direct measurement as we have had in deriving the "generalized rational formula" for train resistance that Mr. Mailloux so "devoutly" wishes for.

Presumably, the authors of the formula do not claim that it is applicable, except for car and track conditions similar to those of the tests upon which the formula is based. The abstract gives a comparison between the Illinois curve and the curves obtained by inserting the car constants of the Illinois test car in several other well-known formulas. In order to compare the Illinois formula with other formulas for other car weights and dimensions than those used in the test, I have calculated the train resistance of a 40-ton car with 100 sq. ft. of front end area (these figures representing approximately the proper values for cars used on several interurban railways in the Middle West), using the Illinois and four other well-known formulas. The results are shown in the first illustration and indicate that the Illinois formula compares with the others as favorably for the 40-ton car as it does for the 28-ton car.



TRAIN RESISTANCE—COMPARISON OF ILLINOIS WITH OTHER WELL-KNOWN FORMULAS

I have also been interested in comparing the results of the Illinois tests with those obtained in tests made under my direction at Purdue University during the past year and recorded in a thesis by H. B. Nussbaum, A. C. Davison, K. Wallace and F. B. Lubker. These tests had for their object the determination of the resistance of a small interurban car operating at low speed over track similar to that found in many small and medium-sized cities in the Middle West. Compared with the track of a high-grade interurban railway on private right-of-way this track would be ranked as below the average. The Purdue University test car used in making the tests weighs about 27 tons and has approximately the same dimensions as the Illinois car. A comparison of the results is therefore of some interest. Such a comparison is shown in the second figure. Because of the low speeds involved the "coasting method" of determining resistance was used in the Purdue tests. The runs were all made over a certain section of track, which had been carefully surveyed just previous to the tests. As in the Illinois tests, runs were made in both directions over the test section. Curve *A* is the average of 296 determinations of train resistance, and curve *B* is the average of 254 determinations, one half of the runs being made with the wind and the other half against it in each case. The rectangles and arrows in the corner of the figure represent the wind conditions. The two curves shown were selected because they represent sets of data taken under approximately similar conditions of weather. The air temperature for both curves was between 70 and 80 deg. F. and both sets of data were taken on fair days. The individual points on the curve sheets were as badly scattered as those shown in the curve sheet, marked "Typical Individual Test," of the Illinois report. Curves *A* and *B* were obtained by taking the arithmetical averages of the determinations with and against the wind. A method similar to the one outlined in the Illinois report was tried in calculating the results of a few of the tests, but as the speed and wind velocities were low, and as factors other than air resistance seemed to affect the curvature of the



TRAIN RESISTANCE—COMPARISON OF ILLINOIS AND PURDUE TESTS graphs, the method was discarded. While the curves *A* and *B* agree fairly well with each other, they show much higher values of train resistance than is shown by the Illinois curve. In presenting these curves of train resistance, it is not intended to disparage in any way the results of the Illinois tests; the idea being to bring out clearly the fact that even when car weights and dimensions are the same, greatly different values of train resistance may obtain. It will be noted that not only are the curves higher up on the sheet, but also that they show a greater curvature than the Illinois curve. Yet at the low speeds involved, the air resistance, to which the curvature of train resistance curves is usually attributed, cannot be an important factor.

The equations of curves *A* and *B* have not been worked out, but they would be of the general form of the McClaurin series, $r = A + BS + CS^2$. The constant terms and the coefficients of S^2 in the equations for the curves *A* and *B* would have much higher values than the similar terms in the Illinois equation. These differences may be attributed to condition and composition of wheel and rail surfaces; contour of wheel face; shape of rail head; elasticity and alignment of track; rigidity of truck frames; distribution of weight on truck frames; arrangement of trucks with respect to the car body; inequality of wheels on the same truck; condition and kind of gears; nature and composition of lubricants; and kind, condition and composition of bearing surfaces.

Any curvature in the graph of an equation of the form given above is due to the influence of the third term which involves the square of the speed. While it is the common assumption that this third term is chiefly concerned with air resistance, there seem to be very good grounds for believing that factors other than air resistance may also have some influence. Car vibrations and oscillations, truck nosing and truck frame skewing use up some of the tractive effort produced by the motors and, as these disturbances are greatly aggravated by poor track conditions and seem to increase at a greater rate than with the first power of the speed, it is easy to see how both the *B* and *C* coefficients may be increased over the values that would obtain for a properly designed car, operating over a first-class roadbed.

Dr. Bell states that the "difficulty of taking care of the air resistance lies in two matters, which have never been really well investigated; first, the actual effect of the shape of the front of the car, and second, the effect of this shape on the lateral drag at high speeds." I would add a third matter, namely, the actual effect of the shape of the rear end of the car. The rear end air resistance certainly is not negligible as compared with the front end air resistance, and it is quite possible that the shape of the rear end has some effect on the lateral drag. D. D. EWING,
Assistant Professor of Electrical Engineering.

"Proceed, Protected by Flag"

STEUBENVILLE, WELLSBURG & WEIRTON RAILWAY COMPANY
EAST LIVERPOOL, OHIO, Aug. 6, 1914.

To the Editors:

I have just read the editorial in the Aug. 1 issue of the ELECTRIC RAILWAY JOURNAL entitled "'Proceed, Protected by Flag'—A Fallacy?" I am strongly against any so called "proceed by flag" rule. A general rule of this nature, while it is very seldom if ever required by a regular scheduled train, is too apt to be seized upon by extra trains with the intention of forcing themselves over the road in the face of opposing regular scheduled trains. Consequently, it is sure to be a very dangerous method of operation.

In the case of block signal operation, I can see that certain instances could arise in the operation of regular scheduled trains whereby some rule should be provided to allow its scheduled operation; for instance, where the train is passing the piece of track over which the regular schedule gives it the right to travel and is approaching a regular scheduled meeting point but is stopped by the failure of a signal to operate, the dispatcher's telephone line being out of commission at the same time. In this case the opposing regular scheduled train would not be allowed to pass its meeting point until the one blocked by the inoperation of the signal had arrived. This is the only possible case to my mind that a rule should be worked out allowing such train to proceed and fulfil its regular rights, but in no wise should any rule allow an extra train of any nature to proceed beyond an inoperative block signal except under the provisions of rules 166 and 167.

W. R. W. GRIFFIN, General Manager.

BOSTON ELEVATED RAILWAY COMPANY
BOSTON, MASS., Aug. 8, 1914.

To the Editors:

With reference to the editorial entitled "'Proceed Protected by Flag'—A Fallacy?" in your issue of Aug. 1, my opinion is that a serious delay that is caused by a complete failure of the signal or dispatching system, and that lasts until such time as operation can be again restored to a safe basis, is preferable to a rule which offers opportunity for a serious catastrophe. If "safety first" means what it says we should not lay ourselves open, if it is possible to prevent it, to one of those harrowing collisions which, the moment they occur, shake the public confidence in the safety of block signals. Under certain local conditions, due to a sparsely settled territory and infrequent service, it may well be that some flagging rule should be devised in order not to tie up the system when telephone communication or signals fail, but it seems to me that only under such conditions is it justified. EDWARD DANA,
Assistant Superintendent of Surface Lines.

NEW YORK, Aug. 10, 1914.

To the Editors:

Your editorial in the Aug. 1 issue on "Proceed, Protected by Flag," is timely. It is my judgment that the rule is not good practice; this on the assumption that operation at high speed is comprehended.

The energies of modern electric railway operation are being directed toward providing greater safety of movement, as witness the development and use of automatic block signals for single track. Such a rule leaves an opening for the failure of the human factor under conditions where such a failure is most likely to occur.

L. H. PALMER.

A municipality in the United Kingdom has applied for sanction to borrow $109,500 with which to purchase twenty-five electric tramcars. The extensions which have been made in the various car routes and the increased traffic will require the utilization in the near future of fifty to seventy-five new cars. About half of these will be built in the company's shops, and the remainder will be purchased. These cars will be of the "double deck" type, inclosed both above and below. Interested American manufacturers may obtain the address of the manager of the tramways by writing to the United States Bureau of Foreign and Domestic Commerce and referring to No. 13,388.

Gergal & Santa Fe Three-Phase Railway —The First Spanish Heavy Electrification

The Gergal & Santa Fé Railway—a three-phase regenerative system which forms an electrified section of the South of Spain Railway is described in a recent article in the *Electric Railway and Tramway Journal*. This line serves an important part of the country situated between Linares and Almeria, and especially the mineral region near Almeria. In 1906 the iron ore traffic of this district became so heavy that the company found great difficulty in carrying on the steam service, especially between Gergal and Santa Fé, inasmuch as the line on this particular section has grades up to 2.8 per cent. The track is of 5-ft. 9-in. gage, which is usual in Spain, and is laid with 73½-lb. rails. This is the first heavy electrification in Spain.

The weights of the trains hauled are about 150 tons, empty, mounting toward Gergal, and 450 tons, loaded, descending toward Santa Fé. Electric locomotives are used solely for the ore traffic, while the less important passenger service is still carried on by steam locomotives. Electrification has raised the up-grade speed from 7 m.p.h. to 15½ m.p.h. and has enabled far heavier loads to be hauled. The time-table is so arranged that two trains run at the same time in each direction and cross each other near the middle of the line at Fuenta Santa. The layout of the line lent itself well to three-phase regeneration, as the descending trains are much heavier than the ascending ones.

POWER GENERATION AND DISTRIBUTION

Power is supplied from a steam station located at Santa Fé at one end of the present line, but midway of the complete Gergal-Almeria electrification. Current is generated at 6000 volts, twenty-five cycles by a 750-kw alternator. The contact line comprises two 8 mm (No. 0) copper wires, the rails serving as the third conductor. The suspension is usually of span type, either with poles or bridges. At stations and in the open the height of the contact wires above the rails is 18 ft. 2 in.; in tunnels, the height varies from 16 ft. 5 in. to 15 ft. 9 in. On open track the span wire is attached at each end to two Ambroin insulators. Galvanized iron clamps permit the span wire to be adjusted vertically to allow the height of the contact wire to be regulated, especially on curves.

Porcelain insulators are used in tunnels and at stations to economize space. The poles are usually 115 ft. apart on tangents and 72 to 92 ft. on curves. The trolley wires are fixed to the span wire by double ebonite and porcelain insulators, each of which has been tested at 10,000 volts, so that the suspension as a whole can withstand 40,000 volts. The line is protected against atmospheric discharges by Wurts lightning arresters. The rails were first bonded with metallic paste, but since then Carpentier-Riviére flexible bonds have been installed. The rails are cross-bonded every 328 ft.

ROLLING STOCK

In choosing the type of locomotives one of the factors which had to be considered was that the load per axle must not exceed 13 tons. The weight of the locomotive was fixed at 52 tons divided upon four driving axles. Each locomotive was built according to the normal twin-coupled design, namely, two axles and two motors per body. In case a half-locomotive is operated, the current collector of the half not in use is dismounted and placed on the other locomotive. The use of a second collector avoids interruptions of current and assures better acceleration. The electrical equipment of the locomotives was constructed by Brown Boveri & Company, and the mechanical equipment by the Ateliers Suisses pour la Construction des Wagons. The first five half-locomotives are of wood, constructed like Spanish box-type freight cars. The leading data of a half-locomotive follow:

Length outside buffers	24 ft. 5 in.
Length between axles	13 ft. 1 in.
Wheel diameter	47 in.
Weight of mechanical equipment	13 tons
Weight of electrical equipment	13 tons
Total weight	26 tons
Adhesion weight	26 tons
Hauled weight toward Gergal, without locomotive	75 tons
Hauled weight toward Santa Fé, without locomotive	225 tons
Weight of motor, including gearing	3 tons

The pole-changing connections of these three-phase, 220-hp (hour rating) motors permit speeds of 7.5 m.p.h. or 15.5 m.p.h., depending upon the use of twelve or six poles. The gear ratio is 1:4.5. At the lower speed the motors have a continuous rating of 160 hp each, and the tractive effort is 45 per cent greater. The contact voltage is stepped down by means of three-phase motor-ventilated transformers, and current is supplied to the motor terminals at 450 volts.

ASSOCIATION NEWS

COMMITTEE ON EDUCATION

The committee on education met at association headquarters on Aug. 12 and 13 to consider the preliminary report which had been prepared by the chairman. Martin Schreiber, engineer maintenance of way Public Service Railway; Prof. A. M. Buck, University of Illinois, and H. H. Norris, ELECTRIC RAILWAY JOURNAL, chairman, were in attendance. The committee reviewed the results of a questionnaire recently conducted to ascertain the present practice of the member companies in regard to apprentice and other employee training. The curriculums which had been prepared for certain correspondence courses were studied in detail and amended. The committee had arranged with a well-known correspondence school to outline several courses suitable for shop, line, power plant, track and other electric railway employees, working under the authority granted by the executive committee in making these preliminary negotiations. After revision the curriculums will be resubmitted to the correspondence school and if acceptable will be included in the committee's report.

The response to the efforts of the committee to interest educational institutions in sending representatives to the Atlantic City convention was considered and the importance of this matter was emphasized by Mr. Schreiber. While the committee agreed that the initiative should be taken by the educational institutions, as a matter of fact they have not done it, and the association has a duty in this direction.

MANUFACTURERS' ASSOCIATION

Secretary McConnaughy's latest circular to the prospective exhibitors at the Atlantic City convention relates to the supply of 110-volt d.c. power which is to be furnished free in reasonable quantities. All electrical connections are to be tested out on Friday, Oct. 9.

At a recent prosperity dinner given in San Francisco John A. Britton, vice-president and general manager Pacific Gas & Electric Company, showed wherein public service corporations have contributed to the welfare of the State. In all communities, he said, there are two main factors—transportation and lighting and industrial motor service—the success of which marks the success of the community and its people. Of primary importance is the matter of transportation.

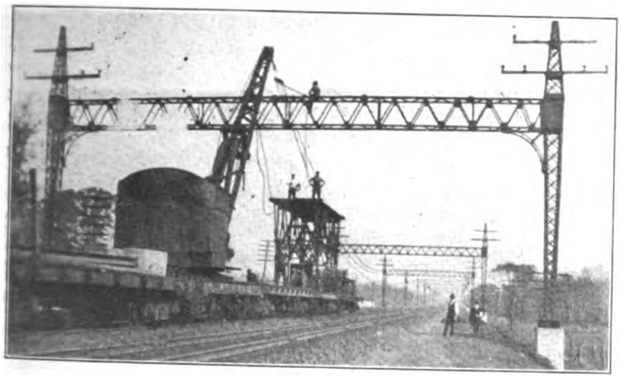
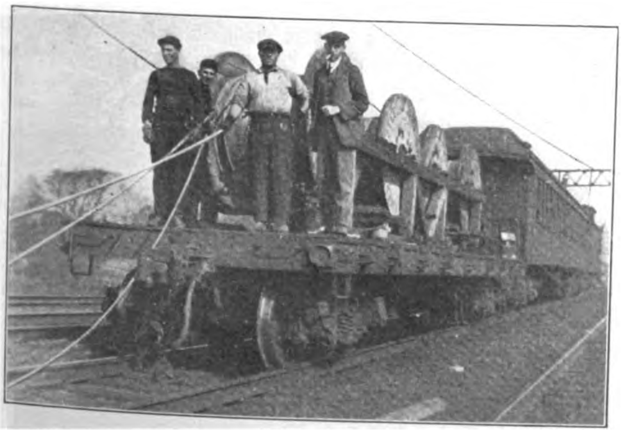
New Haven Railroad Construction Notes—Pulling ⅞-In. Messenger Cable

BY R. M. M. BURTNETT, FORMERLY INSPECTOR NEW HAVEN RAILROAD ELECTRIFICATION

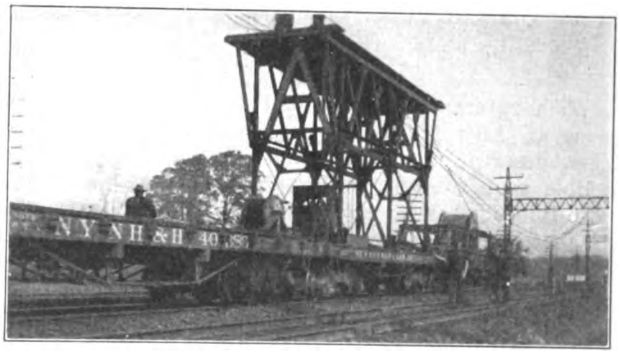
One of the most interesting jobs in the electrification of the New Haven Railroad was the pulling of the ⅞-in. steel messenger cable. These cables averaged about 1 mile in length and weighed about 5 tons. The train used for pulling them was composed of an engine, tool car, a derrick, a tower car and reel car. The reel car was loaded with four reels of ⅞-in. steel cables, as shown in one of the accompanying views. At the point from which the ⅞-in. steel cables were to be pulled the reel car and coach were cut off and anchored by chaining the reel car to the rails. Then the end of each cable was taken to the top of the tower car and connected to an iron plate which had eight holes in it, four for the ⅞-in. steel cable and four for the straps with which the cable was pulled. A ⅝-in. steel cable strap about 6 ft. long was attached to this plate; a second ⅝-in. steel cable strap that reached from the center of the boom of the derrick, provided with hooks on the ends to hook into the plate, held the cable which rested on the tower car while they were being pulled from the reel car to the bridge, and so on from bridge to bridge. After the cables had been attached to the plate the train would move until the tower car was under a bridge. The derrick was then raised and the load line was taken over the top of the bridge and hooked into the shorter ⅝-in. strap. Then the load line was taken up until the other strap was slack. Next the hooks were removed and the train went ahead, the cable being pulled with the load line of the derrick until it was clear of the bridge. Then the derrick was lowered until the plate and cable lay on top of the tower car. Following this the longer strap was hooked into place and the train was run ahead to the next bridge.



TRAIN WITH DERRICK AND TOWER CAR

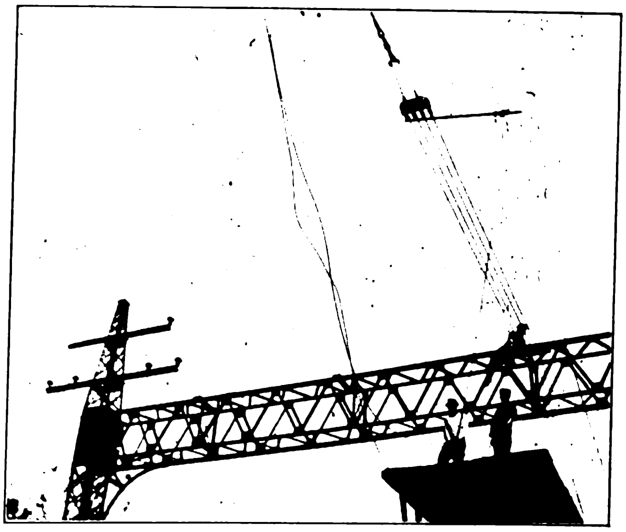


REEL CAR—THE TELEPHONE IS AT THE REAR OF THE CAR ON THE RIGHT



TOWER CAR IN OPERATION BETWEEN BRIDGES

When all the cable was out, sockets were put on and connected to the anchor bridge of the previous run of cable. The cables were then pulled up into the clear, one at a time, by the engine of the train. The movements of the train were controlled over a telephone line that had been distributed by the train from the anchored reel car as the run was made. If the cables were long enough they were dead-ended at the anchor



VIEW OF PLATE, SHOWING ALSO THE LIFTING OF FOUR CABLES OVER A BRIDGE

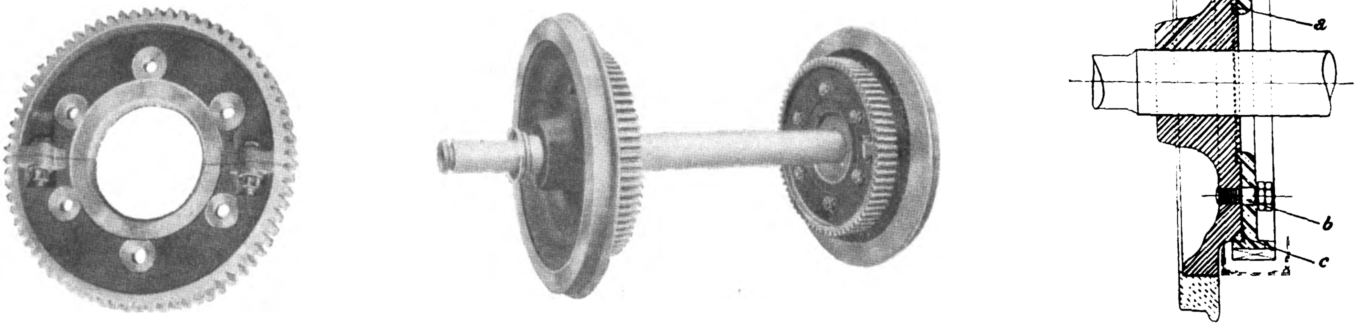
bridge at the other end of the run; otherwise they were dead-ended at the intermediate bridge which had previously been guyed to take the load. After the runs of cables between anchor bridges had been made the wires were separated and put in place over their respective tracks. In some cases we used the boom of the derrick to lift them into place; in other cases the work was done by the field force. Once the cables were in place they were sagged, after which the cables were ready to receive the I-beams, insulators and current-carrying wires.

It may be added that to facilitate the moving of the wires over the catenary bridges and to prevent them from shifting and so fouling other tracks, we installed on the top member of each bridge an iron roller, which was composed of four sections mounted on a wooden block and furnished with a common clamp to hold each wire in place.

Double-Gear Drive for Street Railway Motors

BY C. S. STEAD, A. M. I., MECH. E., ENGINEER TO THE M & G TRUCK & ENGINEERING COMPANY, LTD., LONDON, ENGLAND

With reference to Mr. Blackburn's article in your issue of July 4, relating to the double gear drive, a short description of the method employed to utilize the double gear for street cars operating on a track of 3 ft. 6-in. gage may be of interest. Owing to the amount of space taken up by the motor, it was impossible to fix an additional gear on the axle. It was therefore decided to attach the gears to the centers of the truck wheels. This was carried out in the manner shown in the accompanying drawing.



BIRMINGHAM DOUBLE GEARS AND DETAIL OF INSTALLATION

The wheel centers are of pressed mild steel carefully machined on the inner face to receive the cast-steel gears. The gears are secured in position by turned mild steel studs, *b*, in reamed holes. An annular projection, *a*, on the gear engaging with a corresponding groove in the wheel center preserves the concentricity. The studs are relieved of all driving stresses by two lugs, *c*, situated on the inner edge of the gear rim, which are an accurate fit in machined recesses located in the wheel center. This arrangement is the patented invention of Messrs. Baker and Dickinson of the Birmingham (England) City Tramways.

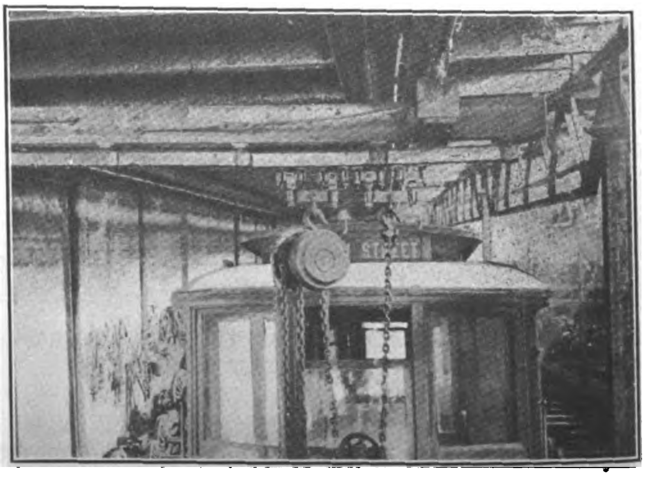
More than 180 car trucks (single and double truck) supplied to the Birmingham tramway system by the writer's firm, have been fitted with wheels upon which this type of double drive has been adopted, and the results obtained during the past two to three years have been exceedingly satisfactory. A distinct advantage obtained by the attachment of the gear to the road wheel center instead of keying the gear to the axle has been found in the freedom from broken axles.

Previous to the introduction of the double drive fractured axles, chiefly at the keyway, were a too frequent occurrence. This trouble is now entirely eliminated. At first sight it would appear as if much trouble would be experienced in obtaining correct alignment of the gears on axle, but by the use of suitable jigs and gages, during manufacture, strict accuracy has been maintained. The gears have seventy-one teeth, the pinions on the Dick-Kerr 19A motor have fifteen teeth.

A second view shows the gear wheel and a third view the wheels and axle with the gears in position.

A Home-Made Traveling Crane

At the Carew Street shops of the Springfield (Mass.) Street Railway effective use is made of two traveling cranes built by the company at a nominal cost. One of these cranes is illustrated in the accompanying halftone, its location being the carhouse storage section adjoining the local forge shop. The crane is built of a main wooden member 7-in. x 8-in. in section, with 7¼-in. x 7½-in. cross pieces near the ends, and a steel bar runway for block and tackle holders at the bottom. The capacity of the hoist is 4 tons, and the runway is 12 ft. long. The cross timbers are each 6 ft. long and are braced against the main member by ⅝-in. tie rods provided with turnbuckles. They are reinforced at the bottom by iron plates 1 in. thick and 6 in. wide. The hoist blocks are carried by hooks and eyes supported from the runway rollers by ½-in. x 2½-in. wrought-iron bars hung from 1¾-in. x ⅜-in. bars by ⅞-in. bolts, the upper bars being attached to the runners by ¾-in. bolts. The runway is attached to the main horizontal member by clamps 30 in. apart. The crane was built at a cost not exceeding $125, including all items relating to labor and material.



HOME-MADE CRANE OF 4-TON CAPACITY AT SHOPS OF SPRINGFIELD STREET RAILWAY

Changes In and Equipment For Car Wiring

BY R. H. PARSONS, ELECTRICAL FOREMAN

If one happens to glance under cars which were wired ten years ago and those which have been equipped within the last six or seven years, most striking differences will be observed. On looking now at the cars in service a decade or more with the original wiring one must wonder how they keep running. The wires and cables are hung around promiscuously in positions where they get the full benefit of the wheel wash or where they are rubbed by the gear cases, motor shells, wheels, etc. The resistors are hung by a couple of bolts down through the car floor, the controllers stand on the platforms with no protection for the cable leads which come in at the bottom and the circuit breakers hang loosely from the bonnet with all the woodwork around scorched from flashes. Further, the cables and wires usually are found to be composed mostly of poor wire, poor splices and screw connectors, while the beams and sills of the car underframe are frequently burned and charred because of short-circuited wires.

On a wet day it was not unusual for passengers to get a bad shock as soon as their feet touched the pavement because of leakage of current through the insulation of the old-time wires; nor was it a rare occurrence for the controller to blow up after seriously burning the motorman and causing panics among the passengers. In almost every one of these cases the controller would be found to have a good-sized hole burned in the cover. The connection board nearly always was found heavily carbonized and covered with many coats of shellac or paint while the wires would be found loose and full of screw connectors.

INTRODUCTION OF CONDUIT

The rules of the fire insurance companies, and still more the desire of progressive railways to avoid burnouts and failures led to the use of conduit and to giving more attention to the location of electrical apparatus for accessibility and safety. Junction boxes and other devices are now used to make watertight joints for the conduit, fire-resisting material is adopted wherever there is any danger from heat or flame, and more care is used in soldering connections. The conduit is grounded to prevent shocks to passengers, and generally the condition of the wiring and other electrical parts is no longer a secondary matter, as was formerly the case.

While it is important that cars fitted for multiple unit control should receive more attention because of the number and importance of the smaller wires, nevertheless if an ordinary car with K control is equipped with conduit completely, using care as to junction boxes, outlets, etc., the investment due to absence of failures and long life of the wiring will also be found to bring ample returns.

Below will be found a list of material, etc., necessary to equip a 45-ft. car with two K controllers and two motors. Although this amount will vary depending on location of apparatus, size of car and equipment, system of lighting, heaters and buzzers, the figures given will generally be found of use when equipping new cars.

WIRING EQUIPMENT FOR A 45-FT. DOUBLE-END CAR WITH TWO MOTORS

Item	Number or Quantity
Lamp receptacles—brass skirt type	17
Lamp receptacles—plain wall socket	2
Lamp receptacles—headlight socket	2

Insulating paint	1 gallon
Solder	5 lb.
¾-in. friction tape	3½ lb.
2-in. friction tape	4 lb.
¾-in. rubber tape	3 lb.

The foregoing material includes all that is used for installing the electrical equipment, to wit, hanging the resistance fastening, all junction boxes, cleating all conduit boards for circuit-breakers and fuse boxes, motor lead brackets, light fixtures, switches, setting up controllers, grounding conduit, placing of heaters, etc.

In connection with the foregoing: As pipe straps and flat washers are ordered by the pound it will be useful to know how many of these make up a pound.

FLAT WASHERS PER POUND

Size	No.	Size	No.
3/16-in.	337	⅞-in.	6
¼-in.	132	1-in.	5
⅜-in.	97	1⅛-in.	5
½-in.	23	1¼-in.	3
⅝-in.	12	1½-in.	2
¾-in.	9		

PIPE STRAPS PER POUND

Size	No.	Size	No.
⅜-in.	33	1-in.	18
½-in.	25	1¼-in.	10
¾-in.	15	2-in.	7

In figuring the weights on a car it will be found useful to know what standard conduit and air pipe weighs per foot.

Conduit Size	Conduit Weight	Air Pipe Size	Air Pipe Weight
⅜-in.	8.4 oz.	⅛-in.	4 oz.
½-in.	14.0 oz.	¼-in.	5 oz.
¾-in.	17.2 oz.	⅜-in.	8 oz.
1-in.	26.4 oz.	½-in.	12 oz.
1¼-in.	34.4 oz.	¾-in.	16 oz.
2-in.	53.6 oz.	1-in.	24 oz.
2½-in.	84.8 oz.		

Insulated wire purchased on specifications best suited for car work weighs per foot as follows:

Size	Weight	Size	Weight
18-strand	0.8 oz.	2-strand	4.0 oz.
14-strand	1.6 oz.	No. 0 strand	7.2 oz.
12-strand	1.9 oz.	No. 4 flexible	4.0 oz.
10-strand	2.0 oz.	No. 2 flexible	5.6 oz.
4-strand	3.6 oz.		

The size of conduit which should be used for various sizes of wires is as follows:

No. of Wires	Size Wire	Size Conduit	No. of Wires	Size Wire	Size Conduit
1	0	¾ in.	1	10	⅜ in.
2	0	1¼ in.	2	10	½ in.
			3	10	¾ in.
			4	10	¾ in.
1	2	½ in.*	5	10	¾ in.
1	2	¾ in.	6	10	1 in.
2	2	1 in.*	1	12	⅜ in.
3	2	1¼ in.	2	12	½ in.
4	2	1¼ in.*	3	12	¾ in.
			4	12	¾ in.
1	4	½ in.	5	12	¾ in.
2	4	¾ in.*	6	12	1 in.
3	4	1 in.	7	12	1 in.
4	4	1¼ in.	8	12	1 in.
5	4	1¼ in.	9	12	1¼ in.
6	4	1¼ in.*	1	14	3 in.
1	6	⅜ in.	2	14	½ in.
2	6	¾ in.	¾	14	½ in.
3	6	1 in.	5	14	¾ in.
4	6	1 in.	6	14	¾ in.
5	6	1¼ in.	7	14	¾ in.
6	6	1¼ in.	8	14	1 in.
7	6	1¼ in.	9	14	1 in.
8	6	1¼ in.*	10	14	1 in.
			11	14	1 in.
			12	14	1 in.

This table is for wire insulated for car work, and is for the sizes mostly used in the equipment of cars.

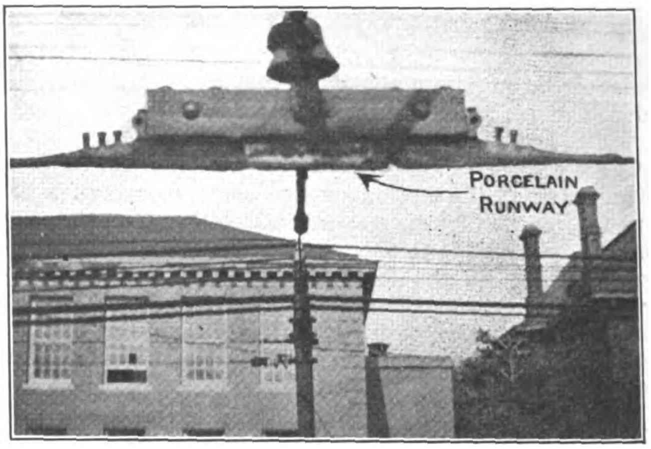
Report on Air in Paris Subways

In a recent issue of *The Engineer*, London, England, is a condensed report on some experiments as to the air in the Métropolitain and the Nord-Sud subways of Paris. The experiments were conducted by the Conseil Hygiene of Paris, and covered a period of two years. The report just issued shows that the air on the Métropolitain is much more vitiated than on the Nord-Sud. The principal cause of the trouble is attributed to the rails. On the Métropolitain the wear is very pronounced, especially owing to braking, in the stations; but on the Nord-Sud the rails are, apparently, of harder steel, and the braking has had little effect. On the former line the brake shoes are of cast iron; on the latter, they are faced with a tar-treated fabric, and, incidentally, the trains on the Nord-Sud stop much more smoothly and with less noise. The report refers to the fact that the floor of the coaches on the Métropolitain has longitudinal strips along the upper surface, so cannot be swept clean, but on the Nord-Sud the floors are covered with a conglomerate material forming a uniform and non-slipping surface, which can be cleaned with sawdust. It is therefore proposed that in these matters the Métropolitain should follow the example of the Nord-Sud, also that the ballast in and near the stations be covered by tiles, which can be swept, so as to reduce the dust.

Porcelain Runways on Section Insulators

BY JAMES SCOTT, SUPERINTENDENT OF OVERHEAD CLEVELAND RAILWAY

As the Cleveland Railway Company had been troubled by the burning and wearing away of the wooden runways on section insulators, it was decided to look around for a substitute. Several different materials were experimented with and finally a porcelain runway of the type shown in the accompanying illustration was adopted.



PORCELAIN RUNWAY IN CLEVELAND SECTION INSULATOR

We have, at present, twelve section insulators equipped with the porcelain runways. These runways have been in use for more than six months and they have yet to show defects. When the wooden runways on the insulators began to wear into "half moons," they caused the trolley to pound and break the wire. The permanent alignment of the porcelain runways overcomes this trouble.

Proposed French Monorail

A scheme for a suspended monorail railway has recently been submitted to the Minister of Public Works in France by M. Mähl, a French engineer. It is claimed that a speed of 150 m.p.h. may be attained with safety on this proposed railway. The track, either single or double, is to be carried 20 ft. to 25 ft. above the ground by catenary suspension. As planned, the trains will be composed of small sections freely articulated and will easily take curves of 1 km (3280 ft. 10 in.) radius and gradients of 1 in 20. Each train section will be suspended from two wheels about 1 m (39.37 in.) apart. There will be only one row of seats, placed longitudinally.

Electric Safety Brake

The Third Avenue Railway, New York, has recently equipped one of its storage battery cars with a new form of electric brake developed by the Electric Safety Brake Company, Philadelphia, Pa. This brake apparatus consists essentially of a pulling or braking cylinder for transmitting power to the truck levers and a controller for controlling the amount of current supplied to the cylinder. The cylinder is a reciprocating or sliding electric motor somewhat resembling an air-brake cylinder. This cylinder is 14 in. in diameter x 42 in. x 50 in. long, with a pulling movement of 12 in. The construction of the cylinder is very similar to that of a d.c. motor, in that it has suitable field magnets energized by separate field coils and a reciprocating or sliding armature with windings, commutator and brushes—imparting a reciprocating instead of a rotary motion. To the armature are attached rods which pass out through the cylinder heads, and attached to these rods is a crosshead to which the usual brake levers are attached.

The winding and arrangement of the cylinder is so proportioned that the movement or pull is smooth and constant throughout its entire length of travel. The amount or strength of the pull is governed by the amount of current supplied, and under normal conditions is from 0 to 1000 lb. for small single-truck cars, and 0 to 1500 lb. for the cylinders of larger truck cars with a maximum current of 75 to 90 amp.

In this type of brake the cylinders either push or pull, as may be most convenient. They are mounted underneath the car body, like an air-brake cylinder, and are connected to the truck levers by any suitable rigging. The cylinder levers are connected to the hand-brake staff and wheel in such a way that at every application of the brake or movement of the levers, the hand-brake staff is operated and all slack is taken up. Hence simply by latching the brake ratchet dog the brake is held applied indefinitely.

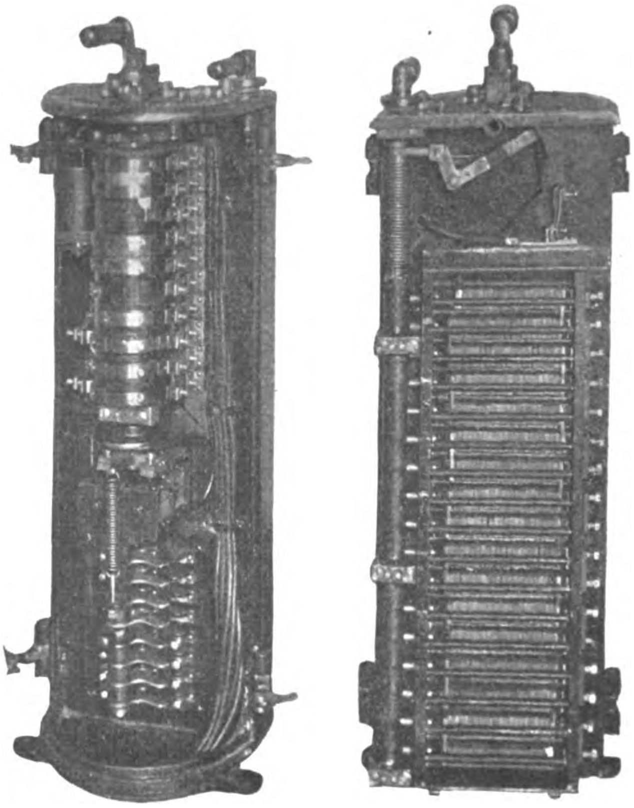
The controller is separate but can be made integral with the main controller. In installing, it is located beside the main controller in the space usually occupied by the air-brake valve and piping. It is connected with the main controller with an interlocking device which prevents the operation of both controllers at the same time. This arrangement prevents the use of power with brake applied or the application of the brake until the power is shut off in the main controller.

The controller consists of two separate parts, the first being the necessary connections, cut-outs, and apparatus for converting either of two motors to a generator to supply energy to operate the cylinder, and the arrangement for controlling this generated current; second, the necessary switches, connections and adjustable variable resistance for the control and application of trolley current for operating the cylinder in emergency, when the car is standing, or at any other time desired. An interlocking arrangement prevents the use of trolley and generated current at the same time.

As the controllers are mounted beside the main controller the only wiring necessary is the circuit for trolley current, one line being from the controller to the cylinder with short connections between the brake and car controllers by which the armature and field leads of two motors are brought into the brake cylinder. All of these wires carry current and are necessary for traction; necessarily any disarrangement would be noticed in propelling the cars and before the need for applying the brakes, thus making the apparatus safe against broken wires.

The apparatus for the control of the generated current consists of a connecting board with a cut-out switch, by means of which one motor is connected for generating use when the switch is thrown to the right, and the other motor connected when thrown to the left. Further, by placing the switch in the center both motors are cut out of the brake controller. From the connecting board and switch suitable connections are made to the fingers and contact points in the controller drum.

The operation is as follows: When the car controller is on the off position, the handle on the brake controller is thrown one notch to the right for car moving ahead, or one notch to the left for the reverse direction. In this position the armature connections to the motor that may be cut in to generate current for braking are broken and are reverse-connected to the field leads from the same motor. Connection is also made with the cylinder, the windings of which are connected in series with the armature, so that all current generated must flow through these windings and be used in the operation of the cylinder. In this position a contact is made which places a short-circuit across the field windings of the motor, thus preventing building up or generating in this position, although all other connections are complete for this purpose.

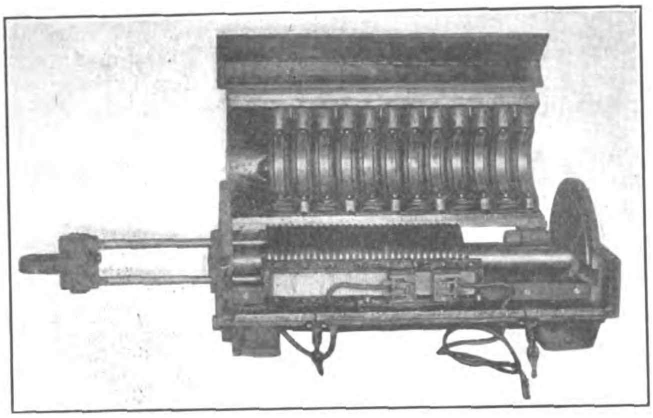


FRONT AND BACK OF CONTROLLER

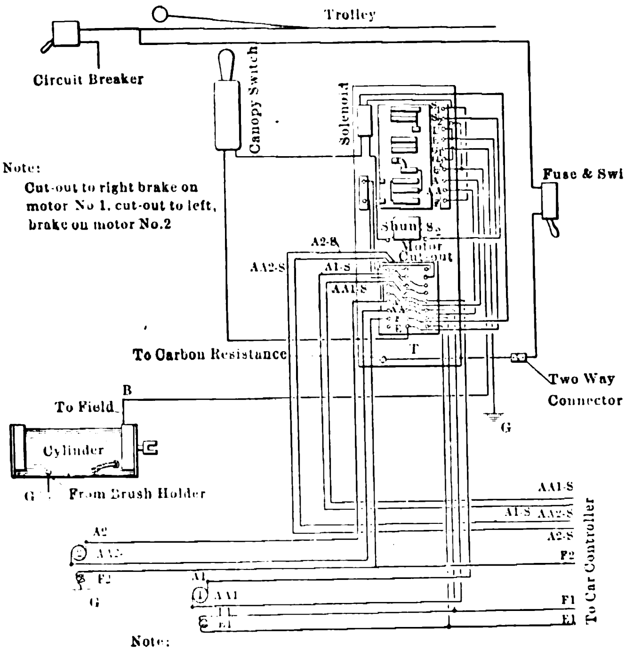
Further movement of the brake handle removes this short-circuit across the fields, which immediately receive current and energize very quickly, and the motor begins to generate current to apply the brake. Wired in series with the armature is a small solenoid set to operate at a low voltage. When the generated voltage reaches this predetermined amount, the solenoid acts to cut in a variable resistance circuit across the field windings. This resistance consists of a small number of clamped carbon blocks, operated by the movement of the controller handle. The movement of the handle causes more or less pressure on the blocks and consequently less of more resistance through them.

At the moment that the solenoid operates to cut in this resistance and current across the fields, the carbon blocks are clamped firmly together to insure little resistance. Hence much current that otherwise would flow through the fields flows through this circuit, with a consequent weakening of the field, and a retardation of the generating of additional voltage. Thus a high voltage is prevented, and the brake is very lightly applied. A further movement of the handle causes a decrease of the pressure on the carbons, and increased resistance in the short circuit. Therefore, more current flows through the fields and higher voltage current is generated to apply the brake to the desired strength.

It might appear that if the brake handle is moved too far, too much current would be generated and the brakes would therefore be applied so hard that skidding would ordinarily take place. This does not occur, however, because the slowing down of the wheels, and the consequent lessening of the speed of the motor armature, decreases the amount of current generated. Consequently, the pull of the brake cylinder would at once be reduced automatically to a point where the two forces would be equalized, and the proper braking of the car would be as rapid as wheel and rail conditions permit. A lesser movement of the handle results in generating a lower current and consequently lower pressure on the brakes. The return of the handle to the first notch again places the short-circuit across the fields, immediately stopping the generating of current and causing the immediate release of the brakes.



ELECTRIC SAFETY BRAKE CYLINDER OPEN



Note: Cut-out to right brake on motor No 1, cut-out to left, brake on motor No.2

Note: A1 s, AA1-s, A2-s, AA2-s are substituted for A1, AA1, A2, AA2 in main controller

Electric Ry. Journal

WIRING DIAGRAM FOR ELECTRIC BRAKE

The short-circuit across the fields prevents current from flowing through or flashing at the various contacts, when the brake handle is brought to the center, the generating connections are broken and the power connections made. The trolley or emergency switch consists of a large number of carbon blocks normally held together with but little pressure. The operation of the switch handle first closes the double switch to close the circuit. As there is little pressure on the carbons and great resistance, very little current flows through at this point. Additional movement of the handle increases the pressure on the carbons by an electric device until the desired pressure with the carbons is obtained to give the current resistance and the amount of current necessary to operate the cylinder.

Test of Oil-Treated Chrome-Vanadium Rolled-Steel Wheels

The Grand Trunk Railway has three lots of tenders, of twenty-five each, equipped respectively with unheat-treated carbon steel tired wheels, oil-treated carbon rolled steel wheels, and oil-treated chrome-vanadium rolled steel wheels, the last two types having been made by the Standard Steel Works Company. Of these three lots of tenders, that equipped with steel-tired wheels went into service between the latter part of January and the first part of March, 1913; that equipped with oil-treated carbon rolled steel wheels in August and September of last year; and that equipped with oil-treated vanadium rolled-steel wheels in November. Comparison is possible because it is stated that though the steel-tired wheels were in service longer than the others, they saw little service during the winter of 1913 and the real test of their merits came last winter.

Careful records were kept by the railroad of the performance of the wheels, particularly as regarded the amount of shelling, as this is stated to be a common defect on the Grand Trunk lines. From these it was found that only three pairs out of 100, or 3 per cent, of the oil-treated, chrome-vanadium, rolled-steel wheels had to be removed on account of shelling. Nine pairs, or 9 per cent, of the oil-treated, carbon, rolled-steel wheels and seventeen pairs, or 17 per cent, of the steel-tired wheels were removed for this cause. In other words, the oil-treated carbon-steel wheels shelled three times as much and the steel-tired wheels five and one-half times as much as the oil-treated, vanadium, rolled-steel wheels.

Further comparison showed that of the oil-treated vanadium wheels only 8 per cent had to be removed from all causes, such as sharp flanges. Of the oil-treated carbon steel wheels 22 per cent, and of the steel-tired wheels 52 per cent had to be removed; in the latter case, the larger number of removals was attributed to their longer service. As regards shelling, however, this circumstance did not affect the comparison with the other two makes. All the cases of shelled steel-tired wheels occurred during the past winter, while none shelled during the short period in which they were in service during the winter months of 1913.

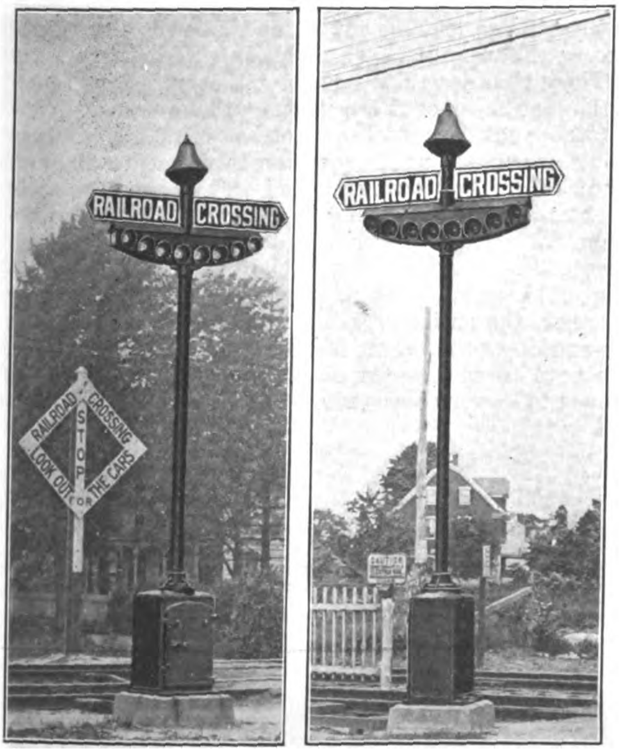
As regards wearing qualities, the oil-treated, chrome-vanadium, rolled-steel wheels showed 68 per cent more mileage per unit of wear than the oil-treated, carbon, rolled-steel wheels. The former averaged 14,500 miles per 1/32-in. tread wear, not including turning, as compared with 8600 miles, the record of the latter. Fair comparison as to mileage and wear without turning with the steel-tired wheels was impossible, owing to the greater length of service of the latter.

Physical and chemical tests of the oil-treated vanadium steel wheels showed a drop-test strength of one specimen wheel in a horizontal position of 1,254,000 ft.-lb. before cranking. The elastic limit ranged between 80,500 lb. and 103,200 lb., depending on location of the test piece in the rim and the elongation ranged between 10 per cent and 18 per cent. Hardness tests showed a practically uniform hardness of 302 Brinnell, and 48 scleroscope throughout the entire section, though a slightly higher degree of hardness was detected in the plate by the scleroscope. The chemical analysis showed carbon, 0.654 per cent; manganese, 0.63 per cent; chromium, 0.992 per cent; silicon, 0.30 per cent; vanadium, 0.16 per cent; phosphorus, 0.039 per cent, and sulphur, 0.047 per cent.

Automatic Flagmen on Long Island Railroad

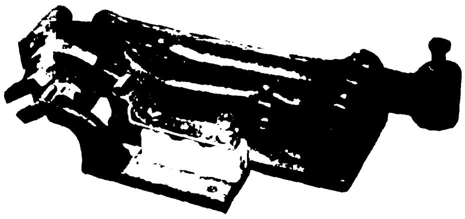
The Long Island Railroad, New York, has recently installed for the protection of two grade crossings the automatic flagmen made by the L. S. Brach Supply Company, New York. The indication consists of the combination of a bright swinging red light imitating that of a man swinging a red lantern and a loud sounding bell of the locomotive type. At Lynbrook, where two of these signals are located, the control is from track contacts, the installation being on the electrified division of the Long Beach branch. The energy for operation and control is taken from the railway's signal service feeder at 2200 volts a.c., and is reduced by transformer to 110 volts, at which potential the signals are operated. The two crossings protected are about 400 ft. apart.

Five track contacts are employed in each direction to start and stop the signal, three of them being starting contacts and two stopping, one at each crossing. The contact arrangement is such that if a train stops within the signal limits the bell will ring only for approximately thirty seconds to a minute. The signal starts as soon as the train is again in motion toward the crossing, and automatically cuts out as the train passes over the crossings. To secure this function, a relay and time element device are employed. These permit a train to come to a stop at a local station within the signal zone and stay there for a period of time without incurring the annoyance of continuous bell or signal operation. Hence the signal indicates only conditions of actual danger.



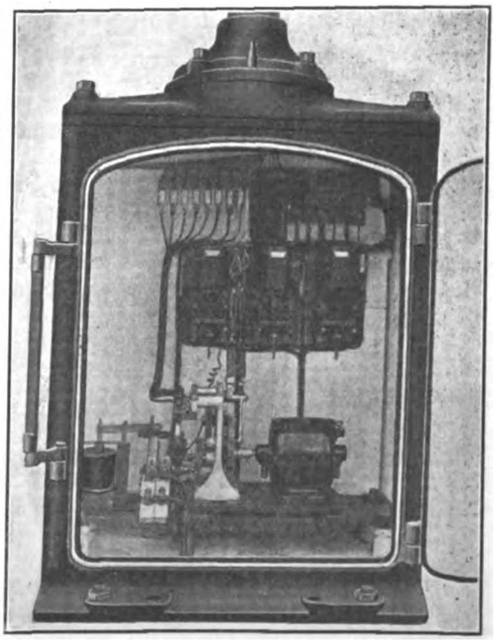
TWO LONG ISLAND CROSSINGS WITH AUTOMATIC FLAGMEN

The swinging red light effect is reproduced by eight stationary lamps located between red lenses, facing both sides of the highway. These lamps are in arc relation and are lighted successively backward and forward from a contact device. The effect of this backward and forward lighting gives the same effect as that of swinging a red lantern, a commonly understood danger warning. By means of concentrating lenses and shadow hoods, the lights are plainly visible in daytime from 1000 ft. to 1500 ft. from the signal under strong sunlight. This visible indication is more powerful and effective than an audible one, although the locomotive type of bell used has greater sound-carrying power than the vibrating type commonly employed.



TRACK CONTACT

Both the bell hammer and the contacts for the lamps are operated from an electric motor in order to avoid the heavy arcing of make-and-break contacts. No movable parts of the signal are exposed. The circuit wiring is such that should any lamp or several lamps go out, the indication will not be affected, because the light would be given by the other good lamps and the indication will skip only the burned-out lamps in its operation. The track circuit wiring is on the "normal danger" plan, so that should a line wire break a continuous danger indication will be given until it has been repaired. At the ends of the signal are two white lenses which indicate the operation to the train motorman. Should the signal fail it can be reported at the end of the trip and prompt repairs made.

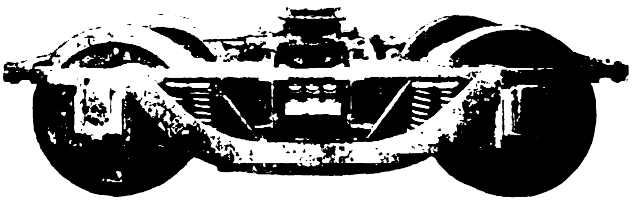


SIGNAL MECHANISM WITH MOTOR

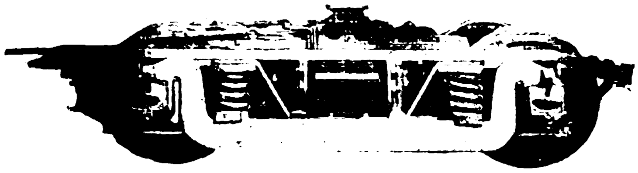
Similar installations of this signal have been in use for some time on the Public Service Railway of New Jersey, the Scranton & Binghamton Railroad and on several steam railroads, including the Central Railroad of New Jersey, Delaware, Lackawanna & Western and the Boston & Maine.

Heavy Service Trucks

The accompanying illustrations show two designs of electric motor trucks, recently built by the Baldwin Locomotive Works for heavy, high-speed service. The truck for the Ohio Electric Railway, designated by the builders as Class AA, is used in interurban passenger service requiring maximum speeds of 50 m.p.h. The track gage is standard, and the sharpest curves are of 45 ft. radius. This truck has a wheelbase of 84 in.; the wheels are of solid rolled steel 36 in. in diameter, mounted on steel axles having 5-in. x 9-in. journals. The transom gussets are of cast steel; they brace the frame and serve as supports for the brakeshoe hangers, and also transmit the greater part of the thrust from the side frames to the bolster when the motors are developing power. The chafing plates on the bolster are case hardened, while those on the gussets are of soft steel. The springs are arranged to insure easy riding qualities, the equalizing beam springs being of the twin coil pattern, while the bolster springs are full triple elliptic. The carrying capacity of this truck is 32,000 lb. on the center plate. The motors are inside hung, one being geared to each axle.



TRUCK FOR MAXIMUM SPEED OF 50 M.P.H.

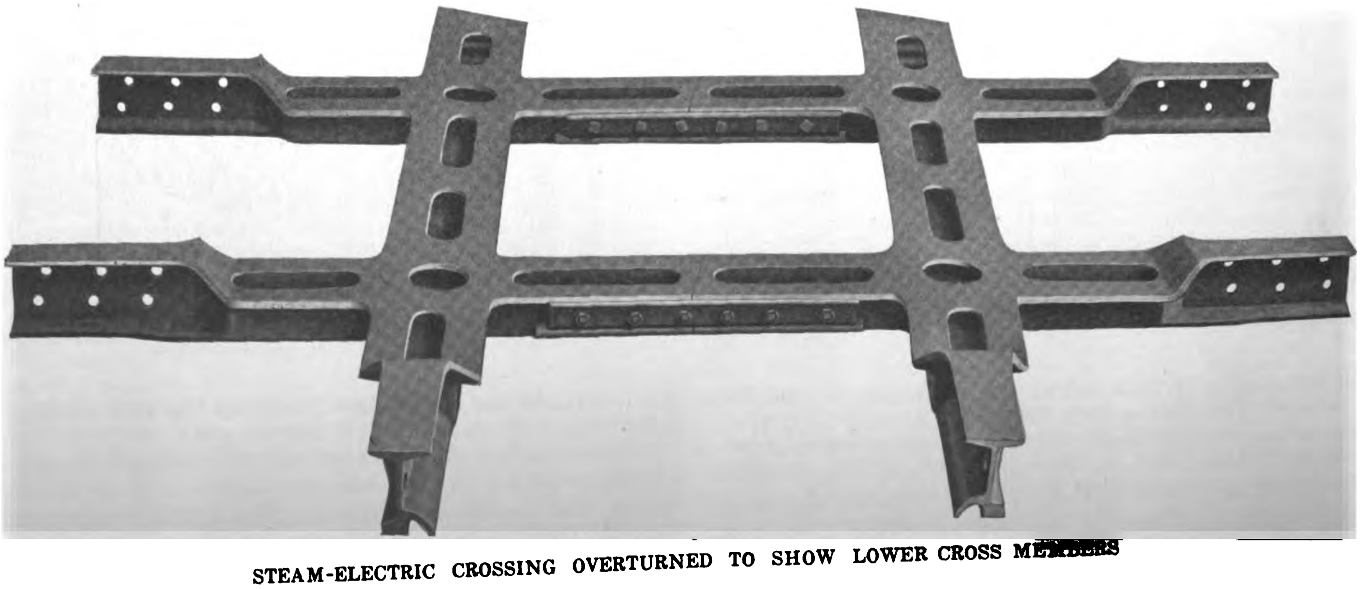


TRUCK FOR MAXIMUM SPEED OF 80 M.P.H.

The truck for the Michigan Railway Engineering Company is specially designed for high-speed service on the new air line shortly to be opened between Kalamazoo and Grand Rapids. The schedule requires an average speed of 50 m.p.h., so that the operating conditions, in this respect, are unusually severe. The track gage is standard, and the trucks are designed to traverse curves of 35 ft. radius. The wheels are of solid rolled steel, 37 in. in diameter, and the axles are of heat-treated steel, with 5½-in. x 10-in. journals. The bolster is a steel casting, equipped with the Bullock swing dampener, a device intended to check the free longitudinal swinging of the bolster in the frame of the truck. The bolster has a central rib, and has openings at each side near each end. A shoe is mounted in each opening and a coiled spring is placed between the central rib and the shoe, so that the latter is forced out against the chafing plate carried by the transom gusset. The shoes are of cast iron with chilled faces, while the gusset chafing plates are of mild steel. The truck frame is unusually strong, and is built as far as possible of commercial shapes so that repairs can be easily effected. The equalizing beam springs are of the double helical type, while the bolster springs are quadruple elliptic. This truck is designed for a center pin load of 50,000 lb., and as far as speed and carrying capacity are concerned it is undoubtedly one of the most notable thus far built for electric railway service.

A New Steam-Electric Crossing

The accompanying illustration shows the latest type of steam-electric crossing made by the St. Louis Steel Foundry Company in accordance with patents which were granted to this company early in July. In the past there have been many failures of solid manganese steel crossings caused by cracks in the bottom of the flangeways at the intersection. While some of these cracks resulted from poor foundry practice, a large part were due to the fact that the crossing was not designed with the proper beam strength across the intersection, some manufacturers leaving out all of the lower cross members in the crossing. These lower cross members are alternately subjected to tension and compression, owing to the movement of the train over the crossing. Without the addition of these bottom members, as here shown, the metal under the flangeway had to carry all this strain. As this metal was only about 1 in. thick and was practically lacking in the neutral motion of the beam, early rupture was sure to occur. The manufacturer of the present crossing believes that with the addition of these lower beam members to tie the crossing together, the entire crossing is made just as strong at the running surface. It is stated that this construction has been in service for about a year, and that it has proved to be very satisfactory.



STEAM-ELECTRIC CROSSING OVERTURNED TO SHOW LOWER CROSS MEMBERS

News of Electric Railways

Bill to Prevent Further Enforcement of Toledo Three-Cent Ordinance

A supplementary bill was filed in the United States District Court on Aug. 7 by the Toledo Railways & Light Company, Toledo, Ohio, asking that the city of Toledo be enjoined from the further enforcement of the Schreiber 3-cent-fare ordinance and that it be restrained from interfering with the withdrawal of cars from the streets on which franchises have already expired and the company be permitted to start them in such places as it may see fit. As Judge Killits is absent on a vacation, it is possible that Judge Clark, Cleveland, recently appointed to succeed Judge Day, will be asked to hear arguments on the supplementary bill. The original bill filed in the Federal Court asked for a receiver for the company, but the court has never been requested to fix a date for a hearing on this request. It has stood as a protection to the company in case any untoward steps were taken by the city.

It is probable that several weeks will elapse before steps are taken by the city in accord with the provisions of the municipal ownership ordinance which was passed by a vote of the electors recently. City Solicitor Thurstin said that the franchise committee should be present when this matter is taken up, in order that the members may take part in formulating plans, but two of the members will be out of the city for some time. Frank L. Mulholland of the Citizens' Franchise Association stated that nothing further can be done by the organization until the city solicitor's department indicates its course. The general understanding is that the city must enact some definite franchise ordinance as a security for the bonds that will be issued to take over the present street railway property or construct new property. The City Council must also take the usual action in providing for the issue of the $8,000,000 of bonds called for by the initiated ordinance. This bond question will then have to be submitted to a referendum vote. The voters apparently took only slight interest in the original ordinance, but when the bond issue comes before them it is expected that practically the full vote will be cast.

Regarding the possibility of disposing of the street railway bonds, various views are taken, but the following extract from a letter from C. E. Denison & Company, Boston, brokers, indicates how one previous bidder for Toledo securities views the proposal passed at the recent election:

"Is it true, as some of our Eastern financial papers write, that your city is proposing to go into the street railway business? We should like to know about this, as we have been recent bidders on your bonds, and in one instance the purchaser of a good sized amount. If you are going into the street railway business we shall probably discontinue bidding on Toledo bonds, as we do not believe in municipal ownership of street railways for United States cities, and we think that the city of San Francisco and the city of Seattle have seriously hurt their credit by going into the street railway business."

This letter was addressed to City Auditor McDonnall, who replied that he felt sure any Toledo bonds held by Denison & Company could be disposed of by his office.

There is still a great degree of uncertainty among those interested at Toledo as to whether a mere majority or a two-thirds vote is necessary in an election such as was held recently. City Solicitor Thurstin himself does not seem certain on this point. At best, he said, a long period will be required in which to take over the property from the present owner.

The following editorial from the Cleveland *Plain Dealer* is interesting in the light of the experience that Cleveland has had in the readjustment of the street railway business:

"Unfortunately for Toledo the approval by the voters on Tuesday of the ordinance providing for municipal ownership will not end the street car war in that city. The fight will be continued with increased bitterness, it is announced. Not only is there a strong element opposed to municipal ownership, but the construction of the ordinance is declared faulty. Claims made by attorneys, whose opinions are entitled to attention, are that the provisions of the ordinance are contradictory and its real meaning obscured.

"It is unfortunate that clearness did not mark the provisions of the ordinance when the city was making so serious an effort to put a troublesome problem out of the way. It is possible to write that sort of an ordinance so misunderstandings are reduced to the minimum. To make clear and definite the language is one step in reaching a solution. It is the foundation on which settlement must rest.

"Much constructive talent in Toledo appears to be arrayed against the settlement on the line of municipal ownership. It is a handicap when such a condition exists. Cleveland found a solution sufficiently troublesome and perplexing even when a great portion of the constructive talent of the city was aiding. A proposition for settlement along the lines of the Cleveland Tayler grant was rejected in Toledo. One wonders if it might have been successful had there been a figure and personality like Judge Tayler to take the leadership.

"Violent opposition to municipal ownership, with a large element of the business interests against the plan, and with legal questions already raised, may serve to hinder and delay the introduction of the policy and will make its adoption and operation exceedingly difficult. With each succeeding contest in other cities where settlement is sought, the far reaching importance of the Tayler plan in Cleveland is shown, and the sound judgment exercised in its adoption is emphasized."

Hearing on Washington Utilities

The committee on the District of Columbia of the House of Representatives held a hearing on Aug. 6 on a bill which directs the separation of the Washington Railway & Electric Company and the Potomac Electric Power Company, Washington, D. C. Those who appeared before the committee were Clarence P. King, president of the Washington Railway & Electric Company; W. F. Ham, vice-president; Capt. Charles Holm, New York, counsel for the company; Paul M. Lincoln, Pittsburgh, and A. K. Baylor, General Electric Company, New York. The Washington Railway & Electric Company owns a controlling interest in the Potomac Electric Power Company.

The principal feature of the hearing was the unexpected proposition advanced by Representative Prouty of Iowa, a member of the committee, that the two companies, instead of being forced by an act of Congress to separate, might be allowed to consolidate. The street railway officials, including Mr. King and Mr. Ham, said that in their opinion such an arrangement would be agreeable to the companies. Mr. Ham, in his statement to the committee, opposed the contention of the Public Utilities Commission of Washington that the Washington Railway & Electric Company has not maintained a proper depreciation account. Mr. Ham said in part: "The facts are that our annual report for the year ending June 30, 1912, to the Interstate Commerce Commission, shows a charge for depreciation of equipment amounting to $93,934. Furthermore, there appeared as a reserve in the report the sum of $550,251, which included a depreciation reserve of $516,290." He presented figures from an auditing company, which said that the railway company is making ample charges for maintenance and a proper provision for depreciation.

The railway officials protested against the separation of the two companies. Representative Prouty's suggestion altered the course of the inquiry, and it is stated that further hearings are likely to be held, with that suggestion in view.

In a letter sent to the company on Oct. 15, 1913, the utilities commission declared that dividends should not be declared without "the creation and maintenance of a sound depreciation account." Mr. Ham informed the committee that since 1902 the dividends paid by the company have averaged only 2.8 per cent. They have been larger of recent years. Mr. Ham questioned the expert knowledge of the commission to prescribe what should be a proper depreciation account for a railway company.

Referring specifically to Representative Prouty's suggestion of a consolidation of the two companies, Mr. Ham expressed the opinion that the time is not far distant when the advantages will be realized of consolidating all the railway companies and the power companies of the District of Columbia. He said this would settle "the transfer problem" once and for all, and would give the companies a sound financial basis, with the prospect of going forward to meet the demands of future growth in the Capital.

A recent attempt to consolidate the railway companies and the power company failed because of public opinion, led by the commissioners of the District of Columbia.

New York Rapid Transit Work to Continue Uninterruptedly

In view of inquiries with respect to the continuation of rapid transit work on account of the present financial situation in this country, Chairman Edward E. McCall of the Public Service Commission for the First District during the week made the following statement:

"The commission will continue to rush the completion of the dual system with all expedition. With so many parts of the system nearing completion or under contract, it is vital that the remaining portions should be constructed at the earliest moment. For example, it is essential that not a moment's time shall be lost on such connections as the Grand Central diagonal station, William Street, Nassau Street and Willoughby Street, Brooklyn. There are now engaged on our work upwards of 11,000 men. I am assured that we will suffer no inconvenience on account of lack of labor. The statements of the financial officers of the city show that while care need be exercised, the rapid transit work may continue to completion. The present crisis shows the wisdom of the dual contracts in so far as complete arrangements were entered into at that time with respect to financial matters."

During the week ended Aug. 8 the commission announced that at its meeting on Aug. 21 it will order advertising for bids for the construction of routes Nos. 43 and 26, the diagonal station at Forty-second Street, connecting the Lexington Avenue subway with the existing subway at the Grand Central Station, bids to be opened Sept. 11, 1914. This is one of the most important contracts yet to be let under the dual system agreements. The contract has now been sent to the Interborough Rapid Transit Company, the operating company, for its criticisms and suggestions, and will be returned by that company within a few days, when it will be put in permanent form by the commission. All contractors submitting bids for this work will be required to deposit a certified check of $75,000 with their bids. The successful contractor will be required to give a bond to the city in the sum of $500,000, and make a deposit, either in cash or securities, of $250,000 to protect the Interborough company. In addition a percentage of all monthly payments will be withheld by the commission until the completion of the work. The entire work must be completed within twenty-eight months from the signing of the contract. The commission's engineers state that the construction of this connection will present many new engineering features, and that it will be one of the most difficult engineering problems in the dual system.

The city has just opened for service the new rapid transit station underneath the gigantic municipal building, in which the heads of most of the city departments and their staffs are located. The station is part of the Centre Street loop line operated by the Brooklyn Rapid Transit System, and is one of the most elaborate of its kind in the world.

The Kansas City Terminal Building Problem

The board of control of the street railway of Kansas City has taken over a part of the duties assigned to it under the new franchise to the Kansas City Railways, but as far as the operating of the system is concerned the company is still the Metropolitan Street Railway, working under the general direction of the federal court and the receivers. P. J. Kealy represents the company and Robert P. Woods represents the city on the board of control, which is also acting under the receivers.

One of the present duties of the board is the selection of a site for the interurban station to be built in accordance with franchise terms. The five interurban lines which will use the station have been unable to agree on a site. The board will hold a public meeting soon and will then make a recommendation to the City Council. The Council, however, may locate the station irrespective of such recommendation. Representatives of four of the five lines have mentioned their preferences for the district within which they wish the station located, and all urge that the site be near the shopping center so that transfers can be avoided.

The Missouri & Kansas Interurban Railway, or the Strang Line, and the Kansas City, Lawrence & Topeka, or the Hocker Line, favor some site between Sixth and Twelfth, Wyandotte and Oak Streets. The Strang Line has its city office at Seventh and Walnut Streets. The Kansas City, Clay County & St. Joseph Railway, which has a ticket office at Thirteenth and Walnut Streets, suggests some location between Eighth and Fifteenth, Oak and Baltimore Streets. The Leavenworth Line suggests one of three sites: (1) Fourteenth and Fifteenth, Main and Baltimore; (2) Thirteenth and Fourteenth, Grand and McGee; (3) Tenth and Wyandotte. The fifth railway, the Bonner Springs line, has not expressed a preference. The Strang, Hocker and Bonner Springs lines enter the business district from the south, the Leavenworth line from the west and the St. Joseph line from the north. In most cases the preferences are for sites that will take the cars through the business district.

Agreement Between New Haven and Federal Department of Justice

The department of justice of the United States and the directors of the New York, New Haven & Hartford Railroad again have reached an agreement on methods for segregating the properties which go to make up the system, and the civil action recently begun by Attorney-General McReynolds has been ended. Instead of standing an action in court the directors have decided to meet the attorney-general half way and return to practically the original arrangement between the government and the road in compliance with the Sherman law. It is said that the entire agreement will be embodied in a decree which will be accepted both by the government and by the railroad officials, and submitted to the United States District Court for approval and record. It is stated that the criminal prosecution of the directors of the company will not be affected by the settlement of the civil action.

At the close of a meeting on Aug. 11 President James H. Hustis, of the New Haven Company, said that an agreement with Mr. McReynolds had been ratified by the directors which was in full accord with the vote of stockholders on April 21, authorizing a settlement with the government. An exception to the first arrangement, he said, was in regard to the disposition of the Boston & Maine stock owned by the New Haven. Mr. Hustis has resigned as a director of the New Haven, as on Aug. 15 he became head of the Boston & Maine. Chairman Elliott has been elected president of the New Haven to succeed him. The resignation of John L. Billard as a director was accepted.

Providence Tunnel Opened

The Rhode Island Company, Providence, R. I., has opened the tunnel from North Main to Thayer Street and discontinued the counterweight system on College Hill. The saving in running time from Swan Point, Butler Avenue, Rumford and Phillipsdale is five minutes, and the Elmgrove Avenue residents gain three minutes over the old schedule. This is due to the elimination of the delays on College Street, the cars now running express from Thayer Street to North Main—a distance of 2165 ft. from portal to portal. Another departure is in sending the west-bound tunnel cars through Exchange Place instead of Market Square and Westminster Street. This adds thirty cars to the ninety-eight previously run during the thirty-five-minute period ending at 6.20 p. m. The time interval is less than seventeen seconds. As traffic increases it is thought that it will be necessary to divert some of the East Side cars through North Main Street to Market Square. This, however, is not contemplated at present, the disposition being to test the new routing thoroughly before taking up the question of relieving the pressure on the northerly tracks in Exchange Place. A third change is the removal of many cars from Westminster Street, the principal retail thoroughfare.

The Los Angeles & San Diego Beach Electrification

Alexander Gordon, of the California Railroad Commission, held hearings recently on a petition to allow an issue of $825,000 in bonds for electrifying the Los Angeles & San Diego Beach Railroad. Raymond B. Talbot, vice-president and general manager of the company, told of the financial affairs of the company and explained the amounts given in the petition as estimates to cover various parts of the work, purchasing of land and erection of new buildings. He said it has been planned to replace the present light rails and erect a power house, a carhouse and machine shop at Pacific Beach. The cost of improvements at Pacific Beach would be about $80,000. The substation at Arctic and Ash Streets, San Diego, will cost about $22,000. The total cost of new equipment will be about $131,000. Mr. Talbot explained that the company, if given permission to issue the bonds, would increase its service materially and fund the present floating debt. A new terminal building to cost about $4,000 will be erected in La Jolla and the company will purchase at least sixteen new passenger cars and seventeen passenger trailers at a cost of about $125,000. The total amount the company expects to expend is $723,198, divided as follows: plant investment, $371,612; new equipment, $131,000; refunding indebtedness, $180,585; interest first year, $40,000.

The Courts and the Toledo Election

The special bench of the Court of Appeals, to which the case against the election for municipal ownership in Toledo, Ohio, was taken after it had been decided in favor of the plaintiff in common pleas court, rendered its decision on July 30, sustaining the decision of the lower court. The question was decided on the grounds that the court did not have jurisdiction and that the petition did not state the cause of action, grounds contained in a demurrer filed by City Solicitor Thurstin in both courts. The decision did not take into account the merits of the case, nor was the efficiency of the proposed municipal ownership ordinance taken into consideration. Judge Winch raised the question twice during the hearing, but the defense contended that it could be taken up on appeal, if the case is carried to the Supreme Court. In making its decision, it is understood that the court did not consider this point at all.

As noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, page 272, the ordinance carried by a plurality of 1100 at the election on Aug. 4. It merely expresses the will of the people who voted and does not carry with it authority to issue bonds. Even now there is doubt as to whether a majority or a two-thirds vote was necessary and the matter may reach the Supreme Court.

Finding for Company in Springfield Arbitration

The arbitration board which has been considering the problem of discipline for improper handling of fares on the Springfield (Mass.) Street Railway has issued a report sustaining the officials of the company in their contention that upon existing evidence three conductors against whom charges had been brought should be discharged from the service. The board found that one other conductor, while somewhat careless and irresponsible in handling fares, should be reinstated without pay for time lost. The board consisted of Gleason L. Archer, dean of the Suffolk Law School, Boston; Henry E. Reynolds, assistant general manager of the Bay State Street Railway, Boston, and M. J. Hennessey of the Amalgamated Association. In a general survey of the situation, Messrs. Archer and Reynolds stated that C. V. Wood, vice-president of the company, acted in good faith and did not desire innocent men to be reported by the inspectors, and that Mr. Wood and R. W. Reynolds, general manager of the Springfield Street Railway, were fully justified on the evidence in discharging the men named. The evidence was presented by eight inspectors. The board found that the evidence had not been discredited. In a brief dissenting report, Mr. Hennessey contended that the evidence was insufficient to warrant the men being found guilty of misconduct, but recommended that the entire award be accepted by the union. This was unanimously done at a meeting subsequent to the announcement of the decision.

Illinois Traction System Issues Newspaper Supplement

The publicity department of the Illinois Traction System has issued a twenty-four page supplement to various daily and weekly newspapers in which it reviews the history of the company and notes the growth and development of the many utility properties controlled by the McKinley syndicate. The many cities and towns through which the lines of the Illinois Traction System and the Chicago, Ottawa & Peoria Railway pass are described and many illustrations are included. The St. Louis terminals and the St. Louis Electric Bridge Company receive much attention, while the new terminal stations and office buildings of the company at Champaign and Peoria are described and carefully illustrated. The freight and express and the sleeping car and parlor car services also receive attention, as do the Decatur shops and storehouses, the block signal system, the many parks and recreation centers and the holiday trips that can be taken on both the Illinois Traction System and the Chicago, Ottawa & Peoria lines. In fact, the supplement reviews the entire work of the company. The supplement was used as an insert in about sixty daily and weekly papers in Illinois on Aug. 6.

Franchise Surrendered for Indeterminate Permits

The Indiana & Michigan Electric Company has surrendered franchises from South Bend, Mishawaka, Elkhart and Town River to the Public Service Commission and will take indeterminate permits therefor. An order of the Indiana Public Service Commission, issued recently, allowed the company permission to issue $150,000 in capital stock to pay debts arising from extensions and betterments of service. The same order rescinded a previous order of the commission which authorized the company to issue $500,000 of bonds. The authorized capital of the company is $3,500,000, and approximately $3,300,000 had been issued before the order of the commission.

Campaign for Hydro-Electric Railways in Ontario

The first meeting in the campaign for hydro-electric radial railways in York and Ontario Counties in Canada was held in Agincourt on Aug. 5 with more than 500 persons present. Reeve J. G. Corbell, Scarboro, was in the chair. He explained that the object of the campaign was to educate the electorate as to the advantages of the proposed new hydro-electric radial railway from Toronto to Port Perry, in order that they could vote intelligently on the by-laws to be submitted by the various municipalities on Sept. 21 to guarantee the bonds for the new line. Sir Adam Beck said that the new road would open many new districts now without any means of transportation and give direct and speedy connection with the city. He expressed himself as confident that a right-of-way could be secured in Toronto giving direct access to the center of the city. He estimated the cost at about $40,000 per mile.

Memorandum by Massachusetts Commission Upon Reduced Rates for Charitable Purposes

The Massachusetts Public Service Commission has issued a memorandum defining the general limitation of free or reduced rate service by steam railroads and street railways for charitable objects. Under Sec. 18, Chap. 784, Acts of 1913, common carriers are prohibited from furnishing free transportation with various exceptions, among which are charitable purposes. The board gave a public hearing to the various companies upon the subject and has reached the conclusion that it would not be consistent with the public interest to permit common carriers to grant free or reduced rate service to any and all kinds of religious and educational institutions. The memorandum says:

"Rather should the operation of this exception to the general prohibition be limited to needy classes, such as the inmates of hospitals, of homes for the aged, of orphans' homes, day nurseries, mothers' outings and other similar undertakings supported by benevolent and charitable societies and intended for the relief of suffering or to furnish opportunities for health to needy children and women and others unable from their own resources to provide the requisite opportunities. Trips for school children, perhaps to visit the

State House, Sunday-school picnics, outings of athletic associations and clubs, and other similar purposes, which are mainly for pleasure and are not intended primarily to relieve any real suffering or need, are not, in the judgment of the commission, charitable purposes to which the carriers ought to contribute by granting free or reduced rate service not available to the general public."

Boston Men in Belligerent Zone

In the last issue of this paper mention was made of a number of electric railway men stranded in Europe. It has since been learned that the plans of several Boston men have been upset by the war. John W. Corning, electrical engineer of the Boston Elevated Railway, is in England. E. W. Holst, superintendent of equipment of the Bay State Street Railway, has returned from Norway. Eliot Wadsworth, of Stone & Webster, was on the *Kronprinzessin Cecilie*, which put back into Bar Harbor. C. S. Sergeant, vice-president of the Boston Elevated Railway, was planning to go abroad this Summer, but has been forced to abandon the idea. His family is now in England.

A special cable to the New York *World* said that the withdrawal of thousands of men from every field of labor has seriously altered transportation in Paris. The underground railway was said to be running only on certain lines, and then only on a much reduced service. The work of the conductors, ticket punchers and other employees called to the front is being done by their wives and sons.

Air Brake Order Asked in Windsor.—The City Council of Windsor, Ont., has applied to the Ontario Railway & Municipal Board for an order to compel the Sandwich, Windsor & Amherstburg Railway to install air brakes on its cars and to provide the necessary equipment for keeping the tracks clear of snow during the winter.

Automobile as Adjunct in Seattle.—If common user rights cannot be obtained soon on the tracks of the Seattle, Renton & Southern Railway on Fourth Avenue, Seattle, Wash., the City Council will consider the operation of a municipal motor bus service connecting Division "A" of the municipal electric railway with the Highland Park & Lake Burien Line, Division "C."

Interstate Commerce Commission Hearing Suspended.—The Interstate Commerce Commission is having at the present time as much of a recess as is possible, for no hearings are scheduled to require the presence of any commissioners during August. Secretary McGinty is visiting the valuation offices of the commission, his first itinerary calling for a trip as far as Kansas City and Chattanooga.

Part of Clover Leaf to Be Electrified.—It is announced that the Clover Leaf Railroad may construct an electric railway from Crawfordsville, Ind., to Cayuga, Ind., where connection will be made with the present tracks of the company, and that the motor car service which extends eastward from Marion, Ind., will be continued west to Cayuga and into Illinois, with the branch from Cayuga to Crawfordsville.

Municipal Ownership Agitation in Alexandria.—The City Commissioners of Alexandria, La., signified their intention of calling an election recently on the question of granting a franchise to the Southern Traction & Power Company on Sixteenth Street from Levin to Marye, and out Marye to the city limits, and on Magnolia and Thirteenth Streets. The advisability of the city endeavoring to take over the property of the company under the provisions of a bill passed recently by the Legislature is being agitated.

Illinois Traction Not to Buy "Black Bridge."—T. W. Gregory, assistant treasurer of the East St. Louis & Suburban Railway, East St. Louis, Ill., has denied that the Illinois Traction System has purchased the "Black Bridge" line of the former company which runs between the Stock Yard district in East St. Louis and Madison, Ill. The Illinois Traction System recently erected a new freight depot at the East St. Louis terminus of the Black Bridge line and is operating express cars to this depot instead of the one at Collinsville and St. Clair Avenues. The Illinois Traction System has trackage arrangements with the East St. Louis & Suburban Railway.

Wage Agreement in Ottawa.—As a result of conferences held recently between the officers of the Ottawa (Ont.) Electric Railway and representatives of the employees, the award of the board of conciliation made in June, 1912, is to be continued for two years from July 1, except that the first and second year men will receive an increase of 1¼ cents an hour and those in the third year of service and upwards a 2-cent increase. This makes the rates as follows: first year, 23 cents; second year, 24 cents; third year and thereafter, 27 cents. Sunday work will be paid for at 2 cents an hour extra over the rates just stated. Increases in wages have been granted in the company's other departments. The rules and conditions of work which have been in force for the last two years remain unchanged.

Through Trolley Trip, Boston to New York.—A trolley trip under the auspices of the Bay State Street Railway will be run between Boston and New York during the week commencing Aug. 16. A through car, said to be the first to cover the entire distance, will leave Post-office Square, Boston, with a party of street railway officials and newspaper men at 8 a. m. on Aug. 17, stopping at New London, Conn., for the night. The car is due at 123d Street, New York, at 6.45 p. m. Tuesday and the distance to be traversed is 282 miles. On Wednesday the return trip will be started with several New York newspaper men as guests. The through service is made possible by the recent completion of a connecting link between Saybrook and New Haven, Conn., and the run is planned to furnish data upon which tourist travel may later be founded.

New Jersey Ferry Fare Case.—The New Jersey & Hudson River Railway & Ferry Company, Edgewater, N. J., as owner of the stocks and bonds of the Riverside-Fort Lee Ferry Company, recently brought suit in the United States District Court against the ferry company, the city of New York and the Board of Chosen Freeholders of Bergen County, N. J., asking that the resolution passed by the freeholders, reducing the fares on the ferry from the foot of West 129th Street, New York, to Edgewater, N. J., from 5 cents to 3 cents for an adult and from 4 cents to 2 cents for children, be declared illegal. The complaint alleged that the reduction would cause a loss to the company of $100,000 annually. Judge Meyer granted an injunction temporarily authorizing the company to continue to collect not less than 5 cents for an adult and 4 cents for a child.

Legislative Expense of the Boston Elevated Railway.—The Boston Elevated Railway has issued the following statement in connection with the filing of its legislative expenses: "The Boston Elevated Railway was interested in upwards of 300 matters acted upon by the Legislature of 1914. The company was not a petitioner for any legislation this year and was represented by counsel and officers of the company only on matters originating on the petitions of others. On some of the matters there were many hearings, the company having been represented at as many as nine hearings upon each of several matters. The statement of legislative expenses for 1914 filed by the company with the secretary of the commonwealth, shows that $7,500 was paid to Gaston, Snow & Saltonstall, and $931.35 to E. P. Saltonstall for legal services, and $659.37 to Edgecomb & Neylan for stenographic reports.

Security Holdings of James Campbell Estate.—According to an inventory of the personal property of the late James Campbell recently filed for probate in St. Louis, Mo., the par value of the securities owned by Mr. Campbell amounts to $16,896,805. It is estimated that the market value of these stocks and bonds is $6,821,237, or $10,065,568 below the par value. The value of the real estate owned by Mr. Campbell is placed at $3,500,000, so that the value of his estate is slightly more than $10,000,000. The stocks in which Mr. Campbell was most heavily interested were 'Frisco common, first preferred and second preferred, Rock Island preferred and Missouri, Kansas & Texas common. In addition to these securities there were included in the list of sixty-eight companies whose securities were held by Mr. Campbell the following: Utah Securities Corporation, par value $4,184,000; St. Louis Transit Company, par value $2,100; North American Company, par value $3,294,500; United Railways Company of St. Louis, par value $118,100; Kirby Lumber Company, par value $90,400; Wagner Electric Company, par value $94,500; Midland Securities Company, par value $50,000, and American Light & Traction Company, par value $43,500.

Financial and Corporate

Holdings of Public Utility Securities

The closing of American stock exchanges has, in its broadest aspect, had no adverse effect on the market for public utilities securities. The prime reason for this is that only a relatively small number of such securities is listed. This, however, has never detracted from their marketability. The bulk of the public utility transactions are through investment houses that specialize in this class of bonds and stocks, selling large quantities of them "over the counter" to the investors. The records of purchases and sales, however, have not been published or even collated.

Certain exact statistics, however, indicate how investors have been turning from other classes of securities to those of public utilities. The report of the Comptroller of the Currency of the United States for the fiscal year ended June 30, 1913, which was referred to in the ELECTRIC RAILWAY JOURNAL at the time of its publication in the spring of this year, presents some illuminating figures concerning the bond holdings of the 26,000 banks of this country. In this fiscal year, as compared to the preceding, bank investments in United States bonds declined 0.2 per cent; in State, county and municipal bonds, 0.9 per cent, and in railroad bonds, 2.1 per cent. On the other hand, the banks' holdings of bonds of public utilities increased 2.1 per cent. The decrease in the banks' investments in steam railroad bonds was $101,400,000 in value, while the increase in public utility bonds held was $118,800,000 in value. This represented an increase of nearly 20 per cent in bank holdings of such bonds.

The largest banking holders of public utility securities are loan and trust companies, with holdings of $334,300,000. National banks come next with $197,400,000; mutual saving banks have about half as much, and state banks hold $52,900,000, or a total of $721,400,000. If United States, state, county and municipal bonds, which form a necessary part of the investments of national and savings banks, are eliminated from the calculation, the holdings of public utility bonds become nearly 22 per cent of the remainder, or more than half as much as the percentage of railroad bonds. The latest available statistics show that the total value of railroad securities in the United States is a little more than $20,000,000,000, while the aggregate value of the operating gas, electric light and traction companies' securities is about $7,500,000,000. From the above statistics it appears that less than one-tenth of the public utility securities are held by the banks, and that the other nine-tenths are in the hands of companies and individuals.

The present popularity of public utility securities bids well to be enhanced during the European war period. Gas and electric consumption and electric railway transportation will continue, which means larger earnings, increased profits and greater stability for the corporations. The general attitude among investment houses regarding the present status of public security issues is shown by the following quotation from the weekly review of Williams, Dunbar & Coleman, New York: "Peculiarly exempt from the various adverse influences now on the financial horizon are public utility securities. Irrespective of the depression in the railroad or industrial stocks and bonds, American public service securities will not be affected. There may be some sentimental reaction in prices, but the attraction for permanent investment will not be impaired."

In accordance with the plan of the Cities Service Company, New York, as noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, to issue a weekly letter to stockholders informing them of the trend of events following the recent deferring of the company's cash dividend, the directors on Aug. 10 issued a statement reading in part as follows: "Many of our stockholders who were not in close touch with the financial condition at the time of the dividend postponement are only now awakening to the severity of the disturbance and may be led to believe that the situation is growing worse instead of better. We believe, however, that the situation is improving daily, and much credit is due to the administration for its prompt supply of emergency currency. Our managers generally report that business continues to be good, but that some difficulty is being experienced in making collections from large customers."

ANNUAL REPORTS

Montreal Tramways

The statement of income, profit and loss of the Montreal (Que.) Tramways for the fiscal year ended June 30, 1914, follows:

Gross earnings	$7,142,804
Operating expenses	4,206,115
Net earnings	$2,936,689
Deduct:	
City percentage on earnings	$527,383
Interest on bonds and loans	787,769
Interest on debenture stock	800,000
Taxes	84,700
Total	$2,199,852
Net income	$736,837
Dividends	242,056
Surplus	$494,781
Less:	
Balance of discount on bonds sold	$82,237
Transferred to contingent renewal account	275,000
Total	$357,237
Transferred to general surplus	$137,544

The gross earnings of the company increased during the year $388,577, or 5.75 per cent; the operating expenses, $173,450, or 4.3 per cent, and the net earnings $215,127, or 7.9 per cent. The ratio of operating expenses to earnings was 58.89 per cent, as compared to 59.71 per cent during the preceding year.

During the year the sum of $417,125 was charged to the contingent renewal account as representing expenditures made for special renewals. An amount of $289,706 was expended on the maintenance of the company's properties, plant and equipment. This amount, taken with the $417,125 noted above, made a total of $1,246,831, or 17.46 per cent of the gross earnings, expended during the year on the upkeep of the company's properties. There was spent on capital account for additional rolling stock, extensions and improvements the sum of $2,711,572. Underlying bonds of the company to the amount of $313,893 were redeemed and cancelled. The amount of the underlying bonds redeemed to date is $838,607.

The report states that large additions were made to the rolling stock of the company during the year, which necessitated extensions of the power requirements. The company also completed a large portion of the rebuilding of its track. The number of revenue passengers carried during the year amounted to 168,472,952. The total number of transfers was 58,120,066, making the number of total passengers carried 226,593,018. The car earnings per revenue passenger were 4.11 cents and the car earnings per passenger total carried, 3.05 cents.

Alabama Traction, Light & Power Company, Ltd.

The Alabama Traction, Light & Power Company, Ltd., New York, which controls the Anniston Electric & Gas Company, Anniston, Ala., the Huntsville Railway, Light & Power Company, Huntsville, Ala., and the Horne Alabama Railway, Power & Manufacturing Company, has issued its first annual report covering the entire period from the organization of the company to Dec. 31, 1913. According to the consolidated balance sheet presented in the report, the property assets of the company as of Dec. 31, 1913, amounted to $27,109,864; investments in other companies, $962,519; bond discount and expenses, $1,783,322, and current and working assets, $463,019, making with a few other small miscellaneous items a total of $30,429,269. Capital liabilities of the company included the following: preferred stock outstanding, $1,000,000; common stock outstanding, $16,975,000, and first mortgage bonds outstanding, $10,902,000. The bonded indebtedness of subsidiary companies not owned by the Alabama Traction, Light & Power Company, Ltd., amounted to $327,800. The current and accrued liabilities totaled $1,129,896; the reserve for accidents and damages, $913, and the surplus, $93,133.

The activities of the company during the period covered by the report were directed principally to construction work on the hydroelectric plant of Lock No. 12 on the Coosa River. A steam plant with a capacity of 15,000 hp was built at Gadsden. It has been operated in conjunction with the company's 2000-hp hydroelectric plant at Jackson Shoals. At present the company has in operation 160 miles of 110,000-volt transmission lines, delivering current through three substations to a distributing system 116 miles in length.

The report does not present any income statement for the holding company or for any of the subsidiaries. It is stated, however, that the earnings at present assured are sufficient to carry the fixed charges on the entire system, including the burden of certain unproductive investments which the company feels it necessary to purchase in order to be in a position adequately to meet future requirements.

Chicago & Interurban Traction Company, Chicago, Ill.—Owing to a misprint, the revenue from transportation of the Chicago & Interurban Traction Company for the year ended Feb. 28 was stated in the ELECTRIC RAILWAY JOURNAL of Aug. 8 as being $209,811 instead of $290,811.

Monterey Railway, Light & Power Company, Monterey, Mexico.—Directors of the Monterey Railway, Light & Power Company have announced that owing to the continuance of the unsettled conditions in Mexico which led to the delay in the payment of the interest on the first mortgage debenture stock due Feb. 1, as noted in the ELECTRIC RAILWAY JOURNAL of March 21, they are compelled to postpone the payment of interest on the first mortgage debenture stock due on Aug. 2, until it is possible to transfer the money on more reasonable terms.

New York, New Haven & Hartford Railroad, New Haven, Conn.—On July 31 the resignation of John L. Billard as a director of the New York, New Haven & Hartford Railroad was announced. This leaves twenty-two directors in the board. As it is desired to reduce the number to nineteen or less, no successor will be elected.

Oakland, Antioch & Eastern Railway, Oakland, Cal.—The California Railroad Commission has authorized the Oakland, Antioch & Eastern Railway to issue $900,000 of three-year promissory notes, bearing interest at the rate of 6 per cent per annum and redeemable at the option of the railway on any interest date at face value and accrued interest on not less than thirty days' notice. The application for these notes was mentioned in the ELECTRIC RAILWAY JOURNAL of Aug. 1. The company is further authorized to issue $330,000 face value of first mortgage 5 per cent bonds and pledge these bonds, together with others heretofore authorized by the commission, as security for the payment of the notes at the ratio of two to one. The notes will be convertible at the holder's option before maturity on the basis of 80 per cent of the par value of the bonds with accrued interest for the par value of the notes with accrued interest. The notes must be sold for not less than 96, provided, however, that the company may pay a commission for their sale of not to exceed 4 per cent. The company will be required to make up by stock assessment during the next three years the discount at which the notes are sold below par. The proceeds are to be used only to pay off floating indebtedness.

Pacific Gas & Electric Company, San Francisco, Cal.—The Pacific Gas & Electric Company is offering the unsubscribed balance of its first preferred stock, amounting to $12,500,000, to the public and is urging its customers to take the new stock. In view of requests from several stockholders the company decided to issue a special circular to its customers dealing with the merits of the stock issue. While the price of the stock to the customers is the same as to the general public, the company points out the advantages to the customers being stockholders in the company supplying them with service. Previous references to this preferred stock financing of the company were made in the ELECTRIC RAILWAY JOURNAL of July 11 and July 25.

The Consolidated Railways, Light & Power Company, Wilmington, N. C.—The Consolidated Railways, Light & Power Company has presented a petition to the City Council for a franchise to change its existing lines. This company is the lessor of the Tidewater Power Company, which recently opposed the granting of a franchise to the Wilmington & Carolina Beach Railway. The City Council on July 29 granted this latter company the right to build and operate an electric road, and adopted a resolution calling for a special election on Oct. 7 to ratify or reject this grant. The proposed city lines of the new company will be about 11 miles in length, and the suburban lines from the city to Wilmington Beach and Carolina Beach will be more than 13 miles. The estimated cost of the lines and the power plant is $750,000.

Toronto (Ont.) Railway.—Seventy-one 4½ per cent currency bonds of $100 each and 322 sterling bonds of £100 of the Toronto Railway, issued under the first mortgage dated Sept. 1, 1892, have been drawn for redemption at par and interest on Aug. 31. Payment will be made at the Canadian Bank of Commerce, Toronto.

United Railroads of San Francisco, San Francisco, Cal.—The California Railroad Commission on July 30 issued a supplementary order authorizing the United Railroads of San Francisco to issue $378,000 of car trust certificates. The original order, which was noted in the ELECTRIC RAILWAY JOURNAL of June 6, provided that the certificates might be paid off in ten years, but the new order enables the railway to pay them off in a shorter time if so desired.

Warren, Brookfield & Spencer Street Railway, Brookfield, Mass.—The foreclosure sale of the Warren, Brookfield & Spencer Street Railway which, as noted in the ELECTRIC RAILWAY JOURNAL of July 25, was set for Aug. 6, has again been adjourned to Sept. 10 on account of the absence of bidders.

Dividends Declared

Central Arkansas Railway & Light Corporation, Hot Springs, Ark., quarterly, 1¾ per cent, preferred.

Connecticut Valley Street Railway, Greenfield, Mass., three-quarters of 1 per cent, common.

Traffic and Transportation

Fare Order of Pennsylvania Commission

In the case of the complaint for a rate of fare over the Lehigh Valley Transit Company's line from Coopersburg to Allentown, Pa., lower than the rate now in effect, the Public Service Commission of Pennsylvania has ordered that the number and extent of the fare zones between Coopersburg and Allentown remain the same as heretofore; that the single return ticket for 25 cents issued at the office of the company at Coopersburg and Allentown continue in effect in the same manner and form as heretofore; that a commutation ticket book containing twenty-five round-trip tickets, good for the calendar month for which it is purchased, be issued as follows: (a) Good between Coopersburg and Allentown, with full transfer privileges in Allentown, for $4.50, thus making it at the rate of 18 cents a round trip. (b) Good between Centre Valley and Allentown, with full transfer privileges in Allentown, for $3.75, being at the rate of 15 cents a round trip.

Coopersburg is a small town located 9 miles from Allentown on the line of the Lehigh Valley Transit Company that extends from the latter place to Philadelphia. The regular rate of fare from Coopersburg to Allentown is 15 cents, but a return ticket can be purchased at the office of the company at Coopersburg or Allentown for 25 cents, thus making the fare each way 12½ cents, or a trifle less than 1.4 cents per mile. These return tickets have no time limit specified on them. The purchaser has the privilege, if he chooses to take advantage of it, of buying one or any number of these tickets at any given time, and is not obliged to call daily at the ticket office to pay his fare for transportation. Moreover, the ticket may be bought by one party and used by another, the ticket being accepted by the carrier from anyone that presents it. The regular one-way fare of 15 cents which must be paid on the car, and the daily return ticket which can be obtained only at the company's office at either end of the trip, are the only rates of fare established by the company between Coopersburg and Allentown.

The commission in its opinion says:

"The complainant avers that respondent issues a monthly commutation fare from other points on its lines about the same distance from Allentown at a much lower rate, and therefore contends that he is discriminated against, and petitions that he be granted the lower commutation rate accorded to the citizens of the aforesaid towns and places located on other divisions of the company's system. While respondent admitted that there are certain towns and places on other branches of its system, located about the same distance from Allentown as Coopersburg that have a lower rate of fare, it also established the fact in the testimony offered that there are other towns and localities on the Coopersburg line situated about the same distance from Philadelphia, Norristown and other centers of population as Coopersburg is from Allentown that have a higher rate of fare than the people of Coopersburg.

"From the various facts and administrative features educed at the hearing, it appeared quite conclusively that existing local conditions are always a factor which must be considered in the work of arranging a correct schedule of rates on the different lines of a transportation plant. The size of the cars operated on a line, the frequency of the service furnished, the density of the population of the adjacent territory, the grades and general alignment of the roadbed, the annual outlay required for repairs and upkeep on the different branch lines, all figure more or less in the rate problem, and must be considered up to a certain point in their proportionate bearing upon the matter.

"Since the hearing held in this proceeding, the company with a view of meeting the wishes of the complainant in part, and of maintaining thereby a spirit of harmony and co-operation with its patrons, has written to the commission that it is willing 'to issue commutation tickets for travel between Coopersburg and Allentown at the rate of 25 cents for a round trip, and between Centre Valley and Allentown at the rate of 16 cents for a round trip, such tickets, in each case, to be bound into books containing twenty-five round trips and to be good for use only on local cars and during the calendar months within which the same were issued, but only when presented by the purchasers in person, accompanied by the book themselves.'

"This proposed change in the rate of fare has been submitted to the complainant by the commission for comment. In his answer to the foregoing readjustment of rates, the complainant contends that the charge of discrimination preferred in the complaint is not removed and asks for a still further reduction in the rates. He requests that he be permitted to purchase for $2.70 'a monthly book containing twenty-five round-trip tickets with full transfer privileges in Allentown,' and for $3 'a book containing twenty-seven round-trip tickets with transfer privileges between Allentown and Coopersburg, good for at least one calendar month,' and that he be permitted to ride between Allentown and Centre Valley on either of two commutation books containing twenty-five and twenty-seven round-trip tickets respectively, which can be obtained at the rate of 10 cents for one round trip.

"It therefore appears that the proposed rates are not satisfactory to the complainant, and the company as intimated in its letter submitting the proposed reduction does not feel warranted to offer any further concessions in the matter. The commission accordingly has made a careful examination of the various local conditions affecting the point at issue, and also of the general principles that must be recognized in the problem of rate making when the transportation service of a general electric railway system is purely local on some lines and interurban and less frequent on other divisions."

After a full consideration of all the different phases and factors involved in the matter, the commission issued an order directing the fare changes previously noted.

Examination of Southern Indiana Employees

Examinations of all the employees of the Insull lines at New Albany in southern Indiana are conducted at regular intervals by James Harmon, safety agent of the company, in connection with the "safety first" work, in order to make sure that trainmen are familiar with the operating rules and other regulations. Ordinarily forty questions are prepared, numbered and typewritten on foolscap paper, with space between the questions for the answers of the men who are examined. A correct and sufficient answer is marked 2½ per cent, the total if the employee has made a perfect record, giving 100 per cent.

Practically all of the questions have a direct bearing on "safety first." A high rating in the examination tells in favor of advancement, while low ratings bring the men who made them into line for special coaching, suspension or dismissal. The sets of questions vary; ordinarily there are special sets for conductors, motormen and trackmen, for city employees and employees of the interurban lines, etc.

Among the examination papers recently turned in by the trainmen of the Louisville & Southern Indiana Traction Company and the employees of the street railway systems of New Albany and Jeffersonville, Ind., across the river from Louisville, was one by J. M. Sams, a motorman on the interurban line, who came through with a perfect score. Some of the questions and answers in Mr. Sams' paper are as follows:

Q—What forms of reading are allowed on duty?

A—Train orders, rule book and instructions, only.

Q—What is a station?

A—A place where trains stop to let off and take on passengers.

Q—What is a dwarf signal?

A—A low, fixed signal with a semaphore arm.

Q—What is a violent signal?

A—Any signal waved violently on or by the track.

Q—What should a motorman do when blowing the whistle is forbidden by law?

A—Ring his gong.

Q—What places should train approach under control?

A—All tongue switches, curves, crossings and special work.

Q—What should be done with a disorderly person?

A—Ask him first to behave himself and be quiet; then, if he will not behave, ask him to get off of car and if necessary put him off.

Q—Should switches be set for opposing train if you were to hold main track?

A—Yes, to save time; but when a switch has been opened for another train and is then left, the switch must be locked.

Q—What should be the speed of a car going over the switch points and frogs on the Big Four Bridge?

A—Four m. p. h.

T. P. Coleman, of the city service, was rated at ninety-seven. All of the answers on Mr. Coleman's paper were perfect except two. These were each marked off 1½ and were as follows:

Q—How should you pass cars at tongue switches?

A—If possible cars should not pass at tongue switches as a switch might split.

Q—How should motormen and conductors look out for passengers?

A—With all possible care.

Some of the other questions and answers from this same paper were as follows:

Q—When should bulletin boards be examined?

A—At all times.

Q—How can you popularize the service in your conduct towards the public?

A—By being polite to all.

Q—What should you do when there is evidence that your car is on fire?

A—Get the passengers off, pull down the trolley and try to put out the fire.

Q—When is conversation forbidden on duty?

A—At all times except when it is necessary to give information.

Q—How should conductors compel passengers to conduct themselves?

A—Like gentlemen or ladies.

Q—How should you report accidents to employees?

A—In no way at all.

Q—What do you use before ejecting a passenger?

A—Everything possible to keep from having to eject him must be done first.

Q—What should motormen and conductors do before assuming charge of their cars?

A—See that everything is as it should be.

A Motorman on Scientific Coasting

About three years ago W. M. Casey, now superintendent of transportation of the Denver (Col.) Tramway, contributed to the *Tramway Bulletin*, published by the company, an article dealing with the economical use of current. Mr. Casey intimated that he thought the motormen were using current until unnecessarily close to their stops. It seems now that a number of the motormen did not at that time agree with Mr. Casey in regard to the economies which he thought might be worked by stricter attention to the ideas he advanced. One of the motormen who disagreed with Mr. Casey in this matter has contributed to the July number of *Tramway Bulletin* his experience after having followed Mr. Casey's advice. The pertinent suggestions made by this motorman in regard to proper coasting methods follow:

"Scientific coasting does not consist solely in keeping the recording clock running the greatest number of minutes per trip, or hours per day, week or month. Scientific coasting is the art of coasting all of the time that you don't actually need to use current to propel your car. For example, A and B are operating cars—each is approaching a street crossing about one block distant; a car, having the right-of-way, is approaching from the opposite direction. A throws off his current and coasts until his car has crossed the street, and proceeds, not having been required to set his brake at all. B keeps current in his motors until near street crossing, makes a heavy application of air, and brings car to a full stop—being compelled, of course, to wait for go-ahead bells. A has saved the power required to propel his car for nearly a block, also the power necessary to replace the air used in making the stop, and the wear on the brakeshoes and wheels. He has also saved his conductor the time and trouble of turning his attention to the car stops and bell-cord.

"The same principle applies to all 'bell,' passenger and regular stops and slow-downs for curves, etc. Coast up to all vehicles or other obstructions on the track, whether moving or not—all current thus saved is clear gain. In my opinion, trying to make a coasting record on an upgrade, where no stop or slow-down is required, is poor economy, as the excess amount of current required to bring car back to speed will offset that saved while coasting.

"The best and most scientific coasting is done by making a good, long coast where a stop or slow speed is called for. The motorman nearly always hears the conductor's bell ring. Beat him to it. Get your current off, and save that much. It is only a little, but means a few ticks on the clock and a considerable saving when practiced on the entire system.

"Get a few ticks on the clock on every stop. I don't care how late or heavily loaded a car may be, it is not only possible but thoroughly practicable to get a few ticks on the clock at almost every stop. Keep your car on time. You lose more coasting getting out of the 'soup' than you do in keeping out. For economy of current get as long a coast as is practicable with the proper handling of a car every time a stop or slow-down is required. Current thus saved is clear gain.

"After all else is said, scientific coasting consists entirely in making an honest effort, being always on the job, and paying strict attention to the task at hand."

Transfer System in Newark

An effective plan of acquainting the public of changes in service rules in public utility operations is illustrated in the method adopted by the Public Service Railway, Newark, N. J., in making known its new general transfer system which went into effect on Aug. 1. Somewhat radical departures from former arrangements such as might easily lead to general confusion and differences among passengers not fully informed were evidenced in the change.

A day or two preceding the installation of the new system, and immediately thereafter, announcements were made in local dailies setting forth just what the various changes embodied. From one general color of transfer for each respective line a change was made to six standard colors, each relating to a particular direction of travel or second transfer, this latter being an added feature of the new system. Further arrangements for these transfers was also perfected in the establishment of zones. All these changes were carefully described in the company's announcement. On the day of the inauguration of the new transfer system only one complaint was registered. The transfer changes were made in connection with the general rerouting of the city lines of the company, as recently sanctioned by the Board of Public Utility Commissioners. The new transfers really extend such privileges, but eliminate the former possibilities of persons "looping" on a single fare. The company intends to continue during August its campaign of educating the public in the improved system along the lines noted.

Cincinnati Fare Case Will Be Appealed to United States Supreme Court

City Solicitor Schoenle of Cincinnati has filed with the United States District Court a petition for appeal to the United States Supreme Court from the decision of the lower court in the injunction case of the Cincinnati & Hamilton Traction Company and the Ohio Traction Company against the city of Cincinnati to prevent the enforcement of an ordinance requiring a 5-cent fare between Cincinnati and Hartwell.

The decision of the District Court was in favor of the companies and the findings were as follows:

That the Cincinnati & Hamilton Traction Company as owner and the Ohio Traction Company as lessee have a perpetual right to maintain and operate a street railway over Erkenbrecher Avenue from the entrance of the Zoological Garden to the Carthage pike, except as to the east 241 ft. of Erkenbrecher Avenue, over which the plaintiffs have the present right to maintain and operate a street railway.

That the plaintiffs have a perpetual right to maintain and operate a street railway over Carthage Pike, from

Ludlow or Erkenbrecher Avenue to the northern terminus of said pike, at or near the Carthage Fair Grounds, by virtue of the grant from the County Commissioners under date of March 23, 1889.

That the plaintiffs have the right at least until Aug. 7, 1919, to operate over Main Street and Lockland Avenue in the former village of Carthage, from the northern terminus of Carthage Pike, to the north corporation line of said former village, by virtue of the ordinance of the village of Carthage, passed on Aug. 7, 1894.

That the plaintiffs have the right to maintain and operate a street railway over Wayne, Rural and De Camp Avenues, in the former village of the Hartwell, at least until Sept. 16, 1921, by virtue of the ordinance of the village of Hartwell, dated Sept. 16, 1896, and May 14, 1900, respectively.

That the plaintiffs have the right to maintain and operate a street railway on the Springfield Pike, from De Camp Avenue to the north corporation line of the city of Cincinnati in the district formerly known at Hartwell, until at least March 14, 1925, by virtue of the grant from the company owning said pike, dated March 19, 1895; and the grant of the Board of County Commissioners of Hamilton County, Ohio, dated March 14, 1900, for a period of twenty-five years.

Illinois Traction System Accident Circular

The Illinois Traction System, Peoria, Ill., has mailed an accident circular over the signature of C. F. Handshy, assistant general manager, to each agent, foreman, head of department and subhead. This circular, which has been posted on all bulletin boards, reads in part as follows:

"The year ended June 30, 1914, shows that there were fewer accidents and personal injuries than during the previous year. This is certainly very gratifying, yet we feel quite well satisfied that the number of accidents can be reduced still further by each employee making it his business to watch not only himself but others in an endeavor to keep down accidents. Employees on trains should watch all passengers, cautioning them, when necessary, as to any possible danger to themselves and the likelihood of accidents or personal injury to others. The number of accidents to persons boarding or leaving cars at railroad crossings has been reduced, but the number is still alarming, and trainmen should give their particular attention to this class of accidents."

Suburban Fare Suit in Cincinnati.—Suit is to be filed by Assistant City Solicitor Constant Southworth of Cincinnati to enjoin the Interurban Railway & Terminal Company from charging more than a 5-cent fare from Cincinnati to Kennedy Heights.

Serving the I. C. C. Order.—The order of the Interstate Commerce Commission in the 5 per cent case, reference to which was made in last week's issue of the ELECTRIC RAILWAY JOURNAL, directs that a copy shall be served upon the carriers directly concerned in the case and also upon a number of agents, including A. L. Neereamer, chairman of the Central Electric Traffic Association.

Interchange with Traction Line.—The Chicago, Ottawa & Peoria Railway, Ottawa, Ill., has begun the construction of a connection with the Chicago, Burlington & Quincy Railroad at Ottawa, Ill. The steam road objected to interchanging traffic with the electric railway, but lost the case before the Public Utilities Commission of Illinois. Traffic rates governing the interchange are now being compiled.

Parking Cars in Indianapolis Streets.—The Indianapolis Traction & Terminal Company, Indianapolis, Ind., has received an extension of the time in which to obey an order made more than a month ago to discontinue parking its cars in the downtown streets of that city. J. Harry Johnson, chief of the Indianapolis fire department, declared that the parking of cars in the streets was a menace to the efficiency of the fire department.

Cincinnati Street Railway Men Enjoy Three-Day Outing.—The annual outing of the street railway men at Cincinnati was concluded on the evening of Aug. 9, having continued for three days. It was held at Chester Park, near the city. The wives and families of the men were present much of the time. A vote of thanks was tendered to General Manager I. M. Martin of the Cincinnati Traction Company and Assistant General Manager J. M. Martin for their co-operation in making the affair a success.

Trespassers on Illinois Railroad to Be Arrested.—With the consent of Governor Dunne the Illinois Public Utility Commission will instruct municipal and railroad authorities to arrest all trespassers on railroad right-of-way. It is believed that people will cease to take such dangerous cut-offs when they realize that they will be fined. A general campaign also will be conducted to educate the public on the danger of grade crossings and to teach them to heed the railroad danger and warning signs. An inspection of all grade crossings in Illinois is now being made, and all dangerous crossings will be ordered protected by the commission and such changes suggested as may be deemed necessary in the cases of crossings already protected.

"Why We Need the Nickels."—The Brooklyn (N. Y.) Rapid Transit System has reprinted in pamphlet form the continued story "Why We Need the Nickels," which appeared as paid advertisements in the Brooklyn newspapers recently. The introductory note printed in the pamphlet follows: "The Brooklyn Rapid Transit System, feeling that a better understanding of some of its problems is necessary to the establishment of that measure of co-operation which the company desires to maintain with its patrons, has issued from time to time chaptered advertisements explaining 'Why We Need the Nickels.' In order that some of our friends may read this story as a whole, we reprint these advertisements and hope that they may be of more than passing interest to all who give attention to the great problem of urban transportation." Some of the advertisements have been reprinted in the ELECTRIC RAILWAY JOURNAL.

Waiting Stations in Manila, P. I.—The *Cable News-American* of June 27 contained the following editorial commenting on the offer of C. N. Duffy, vice-president of the Manila Electric Railroad & Light Company, Manila, P. I., to erect waiting stations for the convenience of the public at the five important junction points in the city: "In another column is published certain correspondence explaining in detail the proposition of the Manila Electric Railroad & Light Company to erect at its own expense waiting stations at five different points in the city, provided the land for the stations owned by the city or the insular government be granted rent free. The company agrees to maintain and provide for the lighting and cleaning of the same. This is good news. The public will appreciate it. When the necessary permission is received, Mr. Duffy promises to commence the construction work at once and estimates that it will be finished within thirty days. The conditions are fair and should receive the immediate attention of the municipal board. The company proposes that the five waiting stations shall be of the same type, dimensions and construction as the one now in service on Calle Taft, opposite the Philippine Hospital."

Regulating Traffic on Fifth Avenue, New York.—Seeking to facilitate traffic movement on Fifth Avenue, the New York City Police Department has recently been experimenting in the half mile between Fortieth and Fiftieth Streets. The problem for all the tests was to move the heavy traffic, principally automobile, simultaneously over this interval in the busy afternoon hours. At each intersection a traffic policeman took orders from a signal flag mounted on a pole in the center of the avenue at Forty-fourth Street. In the first tests arbitrary intervals were chosen—50 sec. for crosstown traffic, succeeded by a period of 2 min. and 10 sec. for Fifth Avenue traffic. Later a change was made by choosing the policeman at Forty-second Street, the principal crosstown thoroughfare in the district, as the key to the system. This officer adjusted the two rectangular movements according to his own judgment, communicating his decisions to the main signalman at Forty-fourth Street, who relayed the signals. Left-hand turns were not allowed during the tests. Though it is stated that the systems tested had aided traffic, the Police Department will carry them further before a decision is made. It has also been suggested that safety zones be established at each street intersection and that all traffic, unless it is going straight, move around these centers counter-clockwise, branching to the right at the desired points. In practice, of course, this system would also be subject to some regulation.

Personal Mention

Mr. George W. Quackenbush has resigned as traffic manager of the Illinois Traction System, Peoria, Ill., effective on Oct. 1.

Mr. James H. Hustis has resigned as president and as a director of the New York, New Haven & Hartford Railroad and will hereafter devote himself to the interests of the Boston & Maine Railroad, of which he is president.

Mr. Howard Elliott, chairman of the board of the New York, New Haven & Hartford Railroad, has been elected president of the company to succeed Mr. James H. Hustis, who continues as president of the Boston & Maine Railroad.

Mr. E. J. Chamberlin, president of the Grand Trunk Railway and the Grand Trunk Pacific Railway, has also been elected president of the Montreal & Southern Counties Railway, Montreal, Que., succeeding the late W. Wainwright.

Mr. Frank Scott, treasurer of the Grand Trunk Railway, and heretofore treasurer of the Montreal & Southern Counties Railway, has been elected vice-president and treasurer of the Montreal & Southern Counties Railway, Montreal, Que.

Mr. Harper Boyd has been appointed superintendent of the Tarentum, Brackenridge & Butler Street Railway, Tarentum, Pa., to succeed Mr. F. C. Hornstein, who has become superintendent of the Lebanon & Ephrata Traction Company, Lebanon, Pa.

Mr. W. M. Hitt has resigned as electrical engineer with the Public Service Commission of Washington to accept a position with Mr. Henry I. Lea, consulting gas engineer of Chicago, who is at present valuing the property of the Seattle Lighting Company.

Mr. Harry G. D. Nutting has resigned as assistant to the president of the Wisconsin Public Service Company, Wisconsin Railway, Light & Power Company, and the Evanston (Ill.) Railway to engage in business for himself as a public utility expert, with offices in Milwaukee, Wis.

Mr. C. C. Trees, who has been auditor and assistant secretary of the Indiana Railways & Light Company, Kokomo, Ind., for the last eight years, has been appointed to the position of examiner of accounts in the valuation department of the Interstate Commerce Commission with headquarters in Chicago.

Mr. J. N. Graham has been appointed to succeed Mr. L. W. Jacques as master mechanic of the Rockford & Interurban Company, Rockford, Ill. Mr. Graham was assistant to the master mechanic of the company for the last three years. Previous to that he was in the employ of the Fort Wayne & Northern Indiana Traction Company at Fort Wayne, Ind.

Mr. Clarke M. Rosecrantz, counsel for The Milwaukee Electric Railway & Light Company and other public service corporations in Wisconsin, has retired from the firm of Van Dyke, Rosecrantz, Shaw & Van Dyke, and will leave Milwaukee to become, on Sept. 1, a partner in the firm of Sullivan & Cromwell, New York, general counsel for the North American Company. Mr. Rosecrantz was formerly employed by Sullivan & Cromwell and since he left eighteen years ago he has been counsel for many public service companies in the West.

Mr. R. L. Rand has been elected vice-president of the Richmond Light & Railroad Company, New Brighton, Staten Island, N. Y., to succeed Mr. H. F. Hazelrigg. Mr. Rand was formerly connected with the Alabama Traction, Light & Power Company, which controls among other companies the Huntsville Railway, Light & Power Company, the Horne Alabama Railway, Power & Manufacturing Company, the Alabama Power Company, the Anniston Gas & Electric Company and the Muscle Shoals Hydroelectric Power Company. He has been engaged in public utility work for more than twenty-five years.

Mr. C. S. Banghart, whose appointment as general manager of the Binghamton (N. Y.) Railway was announced in the ELECTRIC RAILWAY JOURNAL of Aug. 1, was tendered a dinner by the members of the Deportation Club of New York at the Seabourn Hotel, Coney Island, on the evening of Aug. 7. Among those present in addition to Mr. Banghart were W. O. Wood, president of the New York & Queens County Railway, with which Mr. Banghart was connected, and Messrs. W. R. Kerschner, George Robinson, E. R. Mason, Ross Hays, William Wampler, J. H. Denton, Charles Ellicott, Harry Ransom and Edward Smith.

Mr. H. S. Curry, who has been appointed chief dispatcher of the Illinois Traction System, with headquarters at Staunton, Ill., was born in Vinton County, Ohio, on May 30, 1882. Mr. Curry has been in railway work for the last ten years. He started as a conductor for the Springfield (Ohio) Railway. He worked for several city companies previous to 1908, at which time he entered the service of the Dayton & Troy Electric Railway at Tippecanoe City, Ohio. Mr. Curry served this company successively as motorman, dispatcher and timekeeper, resigning on June 1, 1912, to become connected with the Illinois Traction System as train dispatcher.

Mr. F. C. Hornstein, superintendent of the Tarentum, Brackenridge & Butler Street Railway, Tarentum, Pa., has resigned to accept the superintendency of the Lebanon & Ephrata Traction Company, Lebanon, Pa. About six miles of that road are to be constructed to complete the 30-mile run, and Mr. Hornstein will have charge of the construction and will assume the superintendency of the road when it is put into operation. Mr. Hornstein was formerly with the Westinghouse Electric & Manufacturing Company and built the overhead construction of the Tarentum, Brackenridge & Butler Street Railway. When the line was completed he was made superintendent of the company.

Mr. W. W. Waterson, who has been appointed superintendent of the Peoria Division of the St. Louis, Springfield & Peoria Railroad, included in the Illinois Traction System, with headquarters at Mackinaw Junction, Ill., became connected with the McKinley interests at Fort Wayne, Ind., on what was known as the Fort Wayne & Southwestern Traction Company and was employed there in the train service from 1902 until October, 1904. When the Indiana property was disposed of by the McKinley interests Mr. Waterson went to Springfield, Ill., as a trainman with the Illinois Traction System. This was in November, 1904. After being employed a short time in the train service he was promoted to be train dispatcher. He has been connected with the Illinois Traction System continuously since that time and has served in turn as train dispatcher, terminal superintendent, train master, assistant superintendent and superintendent.

Mr. F. R. Edmonston, who has been appointed superintendent of transportation of the Illinois Traction System, Peoria, Ill., having jurisdiction over all lines west and north of Decatur, and south of Springfield, with headquarters in Springfield, was born in Galloway County, Mo., on Dec. 2, 1878. Mr. Edmonston was connected with the Chicago & Alton Railroad at various places on the Kansas City Division, as student-operator and agent from April, 1894, to September, 1896. He was with the Wabash Railroad at various places on the Kansas City Division as telegraph operator, agent, trainmaster's clerk and train dispatcher, from September, 1896, to September, 1907. Mr. Edmonston next entered the service of the Missouri, Kansas & Texas Railroad at New Franklin and Moberly, Mo., serving as train dispatcher and chief train dispatcher from September, 1907, to March, 1913. He was appointed division superintendent of the Illinois Traction Company, Northern Division, on March 10, 1913, and served in that capacity until Aug. 1, 1914, when he was appointed superintendent of transportation with jurisdiction as noted previously.

Mr. John E. Vaughn, general cashier for the Shore Line Electric Railway since July 7, 1913, with headquarters at the general office of the Plant lines in Norwich, Conn., has been appointed purchasing agent of the Shore Line Electric Railway and the Norwich & Westerly Traction Company, both of which are included in the Plant system. Mr. Vaughn was born in Warwick, R. I., on April 25, 1872. He attended the grammar school in Central Village, the high school at Danielson, and was a student at Peddie Institute, Heightstown, N. J., for two years. He entered the service of the dry goods house of the Hartwell-Richards Company in Providence, and worked his way through Brown University. Having completed his studies, Mr. Vaughn went to Boston and passed two more years in the dry goods business. He had overworked his eyes, however, during his studies and was forced to retire from active work for a year. In 1903 he was appointed a conductor on the Worcester & Connecticut Eastern Railway and in May, 1904, was made a clerk on the office of the company. On Jan. 1, 1905, Mr. Vaughn was made cashier and chief clerk of the Consolidated Railway, the successor company. He rendered various services in Webster, Mass., during his term as cashier. He then returned to Dayville and in 1907 went to Norwich and had charge of the office of the Shore Line Electric Railway there for more than six years.

Mr. G. Gordon Gale has been appointed manager of the Hull (Que.) Electric Company. Prior to 1907 he was assistant engineer of the Canadian Rubber Company's electrical plant. From 1907 to November, 1908, Mr. Gale was superintendent of power of the Hull Electric Company and from November, 1908, to 1909 was acting superintendent of the company. From 1909 to June, 1914, Mr. Gale was general superintendent of the Hull Electric Company. He is a graduate of McGill University and an associate member of the Institute of Electrical Engineers, and of the Canadian Society of Civil Engineers. The company of which Mr. Gale has just been appointed manager controls and operates 27.5 miles of electric railway connecting Ottawa, Hull and Aylmer, and furnishes power for lighting. It also owns and controls Queen's Park, Hull. The position of general manager is a new one with the company.

G. Gordon Gale

OBITUARY

Henry C. Wood, associated with the construction of the Aurora, Elgin & Chicago Railroad, Wheaton, Ill., died at his home in Wheaton on Aug. 8. He was a member of the law firm of Wood & Lounsbury, Chicago. Mr. Wood was born in Philadelphia on Oct. 3, 1863, and was graduated from the Columbia Law School in 1886. For two years he practiced law in St. Paul, and in 1888 was appointed United States district attorney at Duluth. In 1892 he went to Chicago and was connected with a number of interurban properties in the Central West during the last ten years.

John R. Bowman, division passenger agent of the Southern Traction Company and the Texas Traction Company, Dallas, Tex., and former private secretary to Governor T. M. Campbell of Texas, is dead. Mr. Bowman was born at Plano, Tex., on April 17, 1876. He was graduated from Southwestern University at Georgetown in 1897. He received his law degree at the University of Texas and studied at Vanderbilt University. He moved to Amarillo and began the practice of law. He was elected to the State Legislature, serving a part of two terms, resigning to become private secretary to Governor Campbell. He became connected with the railways previously mentioned about two years ago.

Henry L. Oestreich, the senior assistant division engineer of the Public Service Commission for the First District of New York, in charge of the Fourth Avenue Subway, died on Aug. 13 in Atlantic City from septic poisoning. Mr. Oestreich was born in New York and was graduated from New York University. He had always been associated in subway building. When the old Rapid Transit Commission began the construction of the original subway in 1900, Mr. Oestreich was assistant engineer to the commission, and had charge of that section from Astor Place to Eighteenth Street. During the next three years he supervised the construction of the sub-surface structures between Fourteenth Street and the Battery, and the Center and Delancey Street subways.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Lehigh-Buffalo Terminal Railway, Buffalo, N. Y.**—Incorporated in New York to build an electric or steam railway in Buffalo. Capital stock, $50,000. Directors: John A. Middleton and Thomas M. Jarvis of New York, and Lyman D. Smith, Brooklyn.

***Ohio River Electric Railway & Power Company, Pomeroy, Ohio.**—Incorporated in Ohio presumably as the successor to the company now operating in Pomeroy. Capital stock, $10,000. Incorporators: I. L. Oppenheimer, J. W. Wolfe, D. W. Hennesey, George Wanger and W. R. Plantez.

FRANCHISES

***Opelika, Ala.**—W. L. Carmack, Opelika, has received a thirty-year franchise from the Council to build an electric railway in Opelika. This is part of a plan to build an electric line between Opelika and Auburn. A company will soon be organized to construct this line, for which right-of-way has been secured.

Los Angeles, Cal.—The Los Angeles Railway has received an extension of time of six months on its franchises from the Council in which to complete its tracks on South Main Street between Slauson Avenue and Manchester Avenue in Los Angeles.

Pomona, Cal.—The Pacific Electric Railway has received a franchise to cross North Garey Avenue and Fulton Road in Pomona. This is part of a plan to build a short cut for the San Bernardino line between Lordsburg and North Pomona.

San Francisco, Cal.—The Daniel O'Day Company has received a franchise from the Council to build an electric railway on the north side of Mariposa Street from the east line of York Street, to connect with the main line of the Ocean Shore Railroad, and to lay a temporary spur track on the west line of Hampshire Street from a connection of the temporary track on Mariposa Street in San Francisco.

Wilmington, Del.—The Wilmington City Railway has received a franchise from the Council to extend its lines to Concord Heights in Wilmington.

***Clearwater, Fla.**—Charles H. Evans, H. A. Murphy and James H. Murphy have received a franchise from the Council to build an electric railway and other public utilities in Clearwater.

Neodesha, Kan.—The Independence, Neodesha & Topeka Traction Company has received a franchise from the Council in Neodesha. This 17-mile line will connect Independence, Neodesha, Altoona and Topeka. T. J. Booth, Independence, president. [E. R. J., July 4, '14.]

Hopkinsville, Ky.—The franchise providing for the construction of an electric railway in Christian County was sold to R. E. Cooper, said to be representing Eastern capitalists who will build the electric line in Hopkinsville. A companion franchise, relating to the city, will be sold on Aug. 22.

Pittsfield, Mass—The Berkshire Street Railway will ask the Council for track locations near the new railroad station in Pittsfield.

Buffalo, N. Y.—The International Railway has asked the Public Service Commission for permission to extend its tracks through Tracy Street to connect the Grant and Elmwood lines in Buffalo.

Ithaca, N. Y.—The Ithaca Traction Company has received the Mitchell Street-College Avenue franchise from the Council in Ithaca, with the stipulation that a double-track be laid in Eddy Street and a ten-minute schedule in either direction maintained.

Schenectady, N. Y.—The Schenectady Railway will ask the Council for franchises to extend its lines in Schenectady to South Schenectady and to the Grand Boulevard. The company will also ask the Board of Trustees in Rotterdam for a franchise.

Wilmington, N. C.—The Tidewater Power Company has asked the Council for a franchise to build several additional crosstown lines in Wilmington.

Wilmington, N. C.—The Wilmington-Carolina Beach Railway has asked the Council for a franchise in Wilmington. This is part of a plan to build an electric line to connect Wilmington and Carolina beaches. Joseph L. Loughlin, secretary. [E. R. J., Aug. 8, '14.]

Wilmington, N. C.—The Wilmington & Fort Fisher Railway has asked the Council for a franchise in Wilmington. This is part of a plan to build an electric line from Wilmington to Fort Fisher Sea Beach, a distance of 18 miles. Lawrence Kure, Wilmington, secretary. [E. R. J., Aug. 8, '14.]

Dartmouth, N. S.—The Dartmouth & Cow Bay Electric Railway has received an extension of time on its franchise from the Nova Scotia Legislature to build this projected railway from Dartmouth to Cow Bay Beach, Halifax County, N. S.

Portland, Ore.—The Portland & Oregon City Railway will accept the franchise for an interurban line on the East Side, to connect up with a line now being built from Oregon City to Portland. The franchise as fixed by the City Council will be advertised for twenty days, after which it will be set up for final passage by the Council. Sixty days after passage, it will go into effect, and the company can begin actual construction and will be given a year's time to complete the work of building the line.

Dallas, Tex.—The Dallas Northwestern Traction Company has asked the Council for an extension of time of six months on its franchise in which to build its line in Dallas. This 50-mile line will connect Dallas, Wichita Falls and Denton. E. P. Turner, Dallas, president. [E. R. J., Feb. 21, '14.]

Danville, Va.—The Danville Traction & Light Company has received a franchise from the Council for an extension of its lines through the eastern section of Danville.

Seattle, Wash.—Councilman Erickson has asked the City Council for a franchise for an extension of the municipal railway into Ballard. The ordinance also instructs the public utilities department to prepare for immediate extension. The extension as proposed will begin at the western terminus of Division "A" and extend in a northwest direction across the recently voted bridge at Fifteenth Avenue Northwest, into Ballard. Provision is made for the construction of the extension by the issuance of public utility bonds. The ordinance was referred to the city utilities committee, which will prepare a definite routing for the proposed railway and work out details of its cost of construction and maintenance.

TRACK AND ROADWAY

Birmingham Railway, Light & Power Company, Birmingham, Ala.—The extension of the Boyles line 1½ miles from Boyles to Tarrant City has been placed in operation.

Edmonton (Alta.) Interurban Railway.—A by-law has been passed authorizing the expenditure of $168,000 by the City Council on electric railway extensions in Edmonton. Plans are being considered to build a line from Edmonton to Fort Saskatchewan, Alta.

Nelson (B. C.) Street Railway.—Plans are being considered to improve and extend this company's lines in Nelson.

British Columbia Electric Railway, Ltd., Vancouver, B. C.—This company has awarded a contract to the Westminster Iron Works to build an ornamental arched entrance to Central Park. The cost is estimated to be about $4,000.

Visalia Electric Railway, Exeter, Cal.—Work has been begun by this company on a 3-mile extension from Woodlake to the base of the foothills in Tulare County.

Pacific Electric Railway, Los Angeles, Cal.—Work has been begun by this company on the extension of the line from Arlington to Corona.

***Niland, Cal.**—Preliminary arrangements are being made to build an electric railway between Niland, Blythe and Seeley. A. L. Faas, Arthur E. Hull, P. A. Raab, G. Ghiglieri and John D. Reavis are interested.

San Francisco (Cal.) Municipal Railway.—The new municipal line in San Francisco from Market Street down Van Ness Avenue to the grounds of the Panama-Pacific International Exposition has been placed in operation.

Norwalk & New Canaan Street Railway, Norwalk, Conn.—This company has awarded a contract to the Conkling & McGrath Company, New York, to build this line between Norwalk and New Canaan. M. W. Conkling, New York, president. [E. R. J., June 27, '14.]

New Smyrna, Fla.—Preliminary arrangements are being made to build an electric railway between New Smyrna, Lake Helen and the St. Johns River. Eventually it will extend on through to the west coast of Tampa. S. E. Carmichael, Lake Helen, is interested. [E. R. J., June 6, '14.]

Lee County Central Electric Railway, Lee Center, Ill.—This company, which purchased the property of the Northern Illinois Electric Railway, operating a 12-mile line between Amboy and Middlebury, plans to extend the line to connect Amboy, Lee Center, Rochelle, DeKalb, Princeton and Dixon. Officers: H. W. Hillison, Franklin Grove, president; William S. Frost, Jr., Franklin Grove, vice-president; S. L. Shaw, Lee Center, secretary; Andrew Aschenbrenner, Amboy, treasurer; C. A. King, general manager and superintendent, and E. S. Virgil, Lee Center, engineer. [E. R. J., July 25, '14.]

Evansville, Chrisney & Eastern Railway, Evansville, Ind.—The bonds of this railway have been disposed of and plans are being made to begin construction within the next two months on the line between Booneville and Chrisney. Eventually it is intended to extend this line to Tell City and Cannelton, Ind. J. P. Chrisney, Chrisney, president. [E. R. J., April 11, '14.]

Evansville & Indianapolis Light, Power & Electric Railway, Evansville, Ind.—Surveys have been completed between Indianapolis and Washington, 80 miles, and surveys are now under way from Washington to Petersburg, 30 miles. This line will connect Evansville and Indianapolis, via Oakland City, Petersburg, Washington, Bloomfield, Worthington and Spencer. Arthur C. Stone, Evansville, president. [E. R. J., Dec. 6, '13.]

Evansville & New Harmony Traction Company, Evansville, Ind.—At a meeting of the officers of this company held at Cynthiana the business men of the town agreed to raise $30,000 to help finance the railway. It is now decided that this line will pass through Cynthiana. [E. R. J., Aug. 1, '14.]

Fort Wayne & Northern Indiana Traction Company, Fort Wayne, Ind.—An agreement was entered into recently between French Quinn, receiver for the Fort Wayne & Springfield Railway, and the Fort Wayne & Northern Indiana Traction Company for the latter to build from Rudisill to McKinnie Avenue in Decatur. The track is to be used by the Fort Wayne & Springfield Railway in Decatur.

***Jeffersonville, Ind.**—Large shipments of cable are being received at New Albany, Ind., preparatory to constructing a high tension line across the Ohio River, to connect the power plant of the Louisville Gas & Electric Company with New Albany and Jeffersonville. It is proposed to lay the cable across the Pennsylvania bridge at Fourteenth Street.

Richmond & Hamilton Traction Company, Richmond, Ind.—Interest in this railway, which was recently incorporated, is increasing, and petitions have been filed signed by the property owners of two townships, one including the city of Richmond, with the county commissioners of Wayne County, asking that special elections be called to vote on the question of subsidies. Eugene Purtelle, promoter. [E. R. J., Aug. 1, '14.]

Sioux City (Ia.) Service Company.—About 1½ miles of track are being relaid in paved streets in Sioux City.

Quebec Extension Railway, Presque Isle, Maine.—Surveys have been completed and plans are being made to begin construction in 1915 by this company for its 100-mile line between Washburn and Quebec. It will extend across the northern part of Maine to connect the existing lines at Quebec and New Brunswick, and across New Brunswick to the Quebec border. [E. R. J., Jan. 31, '14.]

Transcona, Man.—Bids are to be called at once for the construction of the electric line from Winnipeg to Transcona, to be built by J. H. Kern, Moose Jaw. The line is to be completed by December, according to a change effected in the agreement with the Transcona Council. [E. R. J., June 20, '14.]

Winnipeg (Man.) Electric Railway.—The Manitoba Public Utilities Commission has directed this company to prepare plans for the immediate laying of a second track through the St. James subway. The Winnipeg Board of Works has approved of plans for the laying of a second track on Notre Dame Avenue west, to provide a new loop with the Notre Dame, Keewatin Avenue and Logan Avenue lines in Winnipeg. The company has prepared new plans to build a second track on Sargent Avenue and is asking the City Council to approve them.

Grosse Isle Railway, Detroit, Mich.—This company, which was organized several years ago to build a 10-mile electric railway around Grosse Isle, has abandoned the plan to build a railway as it was thought that the transportation upon the island could be taken care of much better in another way. [E. R. J., Aug. 1, '14.]

Michigan Railway, Jackson, Mich.—This company has practically completed its 50-mile line between Grand Rapids and Kalamazoo. H. H. Crowell, 939 Michigan Trust Building, Grand Rapids, president.

United Railways, St. Louis, Mo.—This company has been requested by the Missouri Public Service Commission to extend its Fourth Street line by way of Grand Avenue to the new viaduct entrance to Carondelet Park in St. Louis.

***Bozeman, Mont.**—A new electric railway 150 miles long to cross the Gallatin Valley west from Bozeman and thence to follow Elk Creek over to the Madison Valley, and the Madison Valley south to Yellowstone at the west entrance of the Yellowstone Park is the project now being considered by Eugene W. Dawes, Bozeman, Charles L. Loomis, Kansas City, and associates.

Portsmouth (N. H.) Electric Railway.—The Boston & Maine Railroad, which owns the Portsmouth Electric Railway, is making extensive improvements on this line.

Albuquerque (N. M.) Interurban Railway.—No definite plans have yet been decided upon by this company to begin construction on this line to connect Albuquerque, Jemez Springs, Santa Anna, Almeda, Los Linas and Belen. E. J. Hall, Albuquerque, is interested. [E. R. J., June 21, '13.]

Jersey Central Traction Company, Keyport, N. J.—This company is now engaged in relaying 1½ miles of track in Keyport.

New York Municipal Railway Corporation, Brooklyn, N. Y.—The Public Service Commission has approved a supplementary contract between this company and the George W. McNulty Company, Inc., for the reconstruction of the Sea Beach line. The company is considering plans to extend the Jamaica Avenue elevated line and will soon award contracts for the construction of the branch.

South Flatbush Railroad, Brooklyn, N. Y.—This company, which was incorporated in January, 1909, to build a railroad in the extreme southern part of Flatbush, which never secured a franchise for the route, or issued any stock, was formally dissolved recently, when Supreme Court Justice Van Siclen signed the dissolution order. The proposed route of this line was from Brighton Beach elevated, to West Thirty-fourth Street, to Avenue Q and Flatbush Avenue. The extension of the existing lines so as to serve the territory where the new line was to be operated, caused the abandonment of the project.

Frontier Electric Railway, Niagara Falls, N. Y.—The right-of-way, property and holdings of this company were deeded recently to the International Railway, Buffalo. James S. Simmons, Niagara Falls, president. [E. R. J., Aug. 8, '14]

***Port Jervis, N. Y.**—Plans are being perfected to build an electric line from Port Jervis through Milford, Pa., to the Delaware Water Gap. Plans are being contemplated to purchase the Delaware Valley Railroad and enter East Stroudsburg over that line. The project is said to be backed by Philadelphia capital.

Schenectady (N. Y.) Railway.—Two extensions will be built at once by this company. The South Schenectady extension will extend from the end of the present line in Broadway to the tracks of the West Shore Railroad in South Schenectady. The Grand Boulevard line will be double-track and will extend from the present terminus in Nott Street to the intersection of the Boulevard, and thence to Van Antwerp Road.

Chardon, Jefferson & Meadville Interurban Railroad, Cleveland, Ohio.—Surveys have been completed from Chardon to Jefferson, 30 miles, and are now under way between Jefferson and Linesville, Pa., 18 miles. Grading has been begun. This line will connect with the Cleveland & Eastern Traction Company at Chardon, with the Pittsburgh & Ohio Valley Railway at Jefferson for Ashtabula and the extension to Linesville, Pa., will connect with the Northwestern Pacific Railroad for Conneat Lake, Meadville, Cambridge Springs and Erie. The maximum grade of this line will be 5 per cent. 80-lb. rails will be used and one 100-ft. steel bridge will be built. F. A. Pease, Cleveland, engineer. [E. R. J., June 20, '14.]

Cleveland, Alliance & Mahoning Valley Railroad, Cleveland, Ohio.—The link between Newton Falls and Leavittsburg will be completed by this company within a few months. This will serve as a connection between the group of towns, including Canton, Akron and Alliance, and the group further north, comprised of Warren, Niles, Youngstown and several other important places. Some time ago the line was completed to Newton Falls and it is now in operation from Alliance through Ravenna to this point. When the entire line is completed it will be about 80 miles long. C. R. Morley is president of the company; J. M. Blatt, vice-president, and W. H. Heil, secretary and treasurer, with offices in the Prospect Building, Cleveland. [E. R. J., March 28, '14.]

Toledo, Ottawa Beach & Northern Railway, Toledo, Ohio.—Right-of-way has been obtained by this company for an extension from the present terminus of the railway just south of the city limits of Monroe. It is thought the company eventually will extend its tracks to Monroe.

Interstate Electric Company, Tulsa, Okla.—Application for a charter will soon be made by this company to build a network of interurban electric railways covering the State of Oklahoma. The first line will be from Tulsa to Muskogee and the next one from Tulsa west to Orumright, Cushing and Guthrie. This line will branch at Cushing and go from there to Stillwater, Perry and Enid. C. B. Hale is interested. [E. R. J., July 11, '14.]

***Blenheim, Ont.**—An organization has been formed with Mayor Little, Blenheim, as president, to consider plans to build a hydro-radial railway from St. Thomas to Amherstburg.

Fort William (Ont.) Electric Railway.—It is proposed to build a double track line on Victoria Avenue, as far west as Franklin Street, and a single track from Franklin Street south to Walsh Street in Fort William.

London & Port Stanley Railway, London, Ont.—This railway, the electrification of which the ratepayers authorized last January, is being reconstructed rapidly and will be placed in operation very shortly. The Pere Marquette Railroad has the rehabilitation contract.

Dunnville, Wellanport & Beamsville Electric Railway, Wellanport, Ont.—A resolution has been passed by the Clinton Township Council, asking the Hydro-Electric Power Commission of Ontario to take over this uncompleted line, and incorporate it with a general system of lines to be built under the commission's auspices.

Harrisburg & Mechanicsburg Electric Railway, Harrisburg, Pa.—This company has obtained permission from the Pennsylvania Public Service Commission to apply to the City Council for an extension of its tracks in Harrisburg.

Pittsburgh (Pa.) Railways.—This company is asked to consider plans to build an extension from Avalon to downtown Pittsburgh. The plan is to extend the Avon and Emaworth lines to connect with the West View Park line.

Pottstown & Phoenixville Railway, Pottsville, Pa.—Surveys will be made at once by this company for an extension from Stowe to Reading.

Regina (Sask.) Municipal Railway.—The City Council of Regina has authorized the purchase of one single track, three-part Y with crossover, at a cost of $3,129, which is required for this railway intersection at the north end of the Broad Street subway in Regina.

Wheeling (W. Va.) Traction Company.—Plans are being considered by this company to build a steel and concrete bridge across the Ohio River at Tiltonsville connecting the West Virginia side above Warwood with Tiltonville, Rayland and Yorkville on the Ohio side. It is understood that ground on both sides of the river is now being leased for the purpose.

SHOPS AND BUILDINGS

Birmingham Railway, Light & Power Company, Birmingham, Ala.—The contract for the construction of this company's new building at First Avenue and Twenty-first Street in Birmingham has been awarded to the Realty Construction Company. The Herndon-Mettrick Engineering Company had previously been awarded the concrete contract. The structure will be four stories in height, as nearly fireproof as possible and is estimated to cost about $75,000.

Calgary (Alta.) Municipal Railway.—A proposition is under consideration in Calgary for the erection of a public utilities building, in which would be combined offices, recreation rooms for the employees of the Calgary Municipal Railway and other departments, and a public waiting room.

Pacific Electric Railway, Los Angeles, Cal.—This company has awarded a contract to the Alta Planing Mill Company, Los Angels, to build a new passenger station in El Segundo. The structure will be 58 ft. x 38 ft. and of mission style of architecture. It will have a long platform for loading freight.

Peoples' Traction Company, Galesburg, Ill.—The present passenger station for this company and the Rock Island Southern Interurban Railway will be vacated. It is reported that the new depot will be in the Galesburg National Bank Building in Galesburg.

Brooklyn (N. Y.) Rapid Transit Company.—This company has opened its new station under the Municipal Building for the trains running through the Centre Street Loop in Brooklyn.

Wheeling (W. Va.) Traction Company.—Contracts have been awarded by this company to build a new carhouse at McMechen, for the Moundsville division of this railway. The structure will be of steel, concrete and brick construction.

POWER HOUSES AND SUBSTATIONS

Birmingham-Tuscaloosa Railway & Utilities Company, Birmingham, Ala.—It is stated that this company has closed a contract with the Alabama Power Company to secure its water power for the operation of the electric railway in Tuscaloosa. This company plans to have its line to Tuscaloosa completed by October.

Pacific Electric Railway, Los Angeles, Cal.—This company's power house at Watts was partly destroyed by fire on July 30.

Jersey Central Traction Company, Keyport, N. J.—During the next few weeks this company plans to install at its power house in Keyport 1000-hp Sterling boilers lately purchased from the Babcock & Wheeler Company.

Public Service Railway, Newark, N. J.—This company has awarded a contract to Linde & Griffith, Newark, to build its new power plant at Point-no-Point. The plant will be erected on the banks of the Passaic River, north of Lincoln highway. Contracts have been let to build concrete foundations for a turbine-room, 95 ft. x 160 ft.; a boiler house, 124 ft. x 168 ft.; an outside coal bunker, 48 ft. x 56 ft., and a detached switch house, 70 ft. x 105 ft. The main building will be 160 ft. x 264 ft.

Wheeling (W. Va.) Traction Company.—Plans are being made to build a new power plant and generator station on the site of the present power house on Water Street, near Forty-first in Wheeling. The walls are to be built of brick and reinforced concrete. The building is being constructed about the present structure, and when completed the old walls will be razed.

Manufactures and Supplies

ROLLING STOCK

Empire United Railways, Syracuse, N. Y., which was reported in the Electric Railway Journal of Aug. 1 to be in the market for twelve interurban cars, has awarded the contract for these cars to the St. Louis Car Company.

Calgary (Alta.) Municipal Railway has received from the Preston Car & Coach Company a street sprinkler of 5000 gal. capacity with adjustable sprinkler heads at all four corners and a direct connected centrifugal pump so arranged that it can be used for fire fighting.

Los Angeles & San Diego Beach Railway, San Diego, Cal., will purchase sixteen new motor cars and a similar number of trail cars if the application which it has pending before the Railroad Commission of California for permission to issue bonds to electrify its line is granted.

Pacific Electric Railway, Los Angeles, Cal., is reported to be considering the purchase of forty-four all-steel interurban cars for the new line extending for 59 miles between Los Angeles and San Bernardino. This new line, of which a brief description was published in the Electric Railway Journal for July 25, page 163, is now being operated with rebuilt cars intended only for temporary use.

New Orleans Railway & Light Company, New Orleans, La., has specified the following equipment for the fifty closed motor cars which it ordered recently from the Southern Car Company for delivery in October, November and December:

Seating capacity	55
Weight (car body only),	16,000 lb.
Bolster centers, length	23 ft. 5¼ in.
Length of body	34 ft. 8 in.
Over vestibule	47 ft. 8 in.
Width over all	8 ft. 7 in.
Height, rail to top trolley board	11 ft. 3⅝ in.
Body	Metal
Interior trim,	Wood and metal
Headlining	Agasote
Roof, type	Arch
Underframe	Metal
Bumpers,	Hedley anti-climber
Car trimmings	Bronze
Conduits and junction boxes	Sheroduct
Curtain material	Pantasote
Destination signs	Keystone
Hand brakes	Dayton handle
Headlights	Crouse-Hinds
Motors	G.-E. inside hung
Registers	International
Sash fixtures	Edwards
Seats, style,	H. & K. No. 300 A
Seating material,	Cherry slats
Step treads,	American abrasive
Trolley catchers or retrievers	Earle
Trolley base	G. E.
Trucks, type	Brill 39-E
Ventilators	Railway Utility

TRADE NOTES

Pathé Frères, New York, N. Y., the French moving picture firm, announces that Arthur Roussel and L. P. Bonvillain, its ranking vice-presidents in America, are Frenchmen and that Mr. Bonvillain, together with other employees, is about to sail to join his regiment in France. Mr. Roussel is ill in New York and has not been told about conditions abroad. The immense factory of the company near Paris has been requisitioned by the government as a barrack for soldiers.

Union Switch & Signal Company, Swissvale, Pa., has received a contract from the Indianapolis Railway & Lighting Company, a 600-volt interurban line, for the installation of a.c. automatic block signals between Pit and Junction, 7.2 miles in Indiana. There will be eight model No. 13 electric light signals installed on the TDB system which will permit two trains to follow each other between turnouts but will prevent opposing movements. Vane relays will be used on the line circuits and galvanometer relays on track circuits.

Railway Utility Company, Chicago, Ill., reports orders for its thermostat control to be used on the 228 cars recently ordered by the Chicago Surface Lines, 100 cars ordered by the Pittsburgh Railways and twenty-five cars ordered by the Third Avenue Railway, New York. Utility ventilators have also been ordered for the vestibules of the 228 cars ordered by the Chicago Surface Lines and for fifty cars ordered by the New Orleans Railway & Light Company, and the twenty-five cars ordered by the Third Avenue Railway, New York.

William R. Garton, New York, N. Y., sales engineer, has been appointed as exclusive general sales agent in the United States and Canada for the Zink adjustor and Zink radius, or circle bar brake connection. The Zink adjustor takes the place of all turn buckles used in connection with brakes. It can be adjusted readily and remains in fixed position until readjusted. It is in use on some of the largest properties. The radius or circle bar connection avoids the binding of brake bars and rods on double trucks when the truck is on a curve or standing at an angle.

General Electric Company, Schenectady, N. Y., has received the order for motors on the 100 additional steel cars to be purchased by the New York Municipal Railway Corporation under recent authorization by the Public Service Commission of the First District of New York. This order of 200 motors is a duplicate of the order that was placed for the first lot of cars for operation in new subways in New York City, covering 140 hp equipments of the GE-248 type without control equipment. The General Electric Company has also received an order for one 3000-kw rotary converter from the Transit Development Company for use on the Brooklyn Rapid Transit System. This includes the necessary transformers and switchboards for the converter, which will be a duplicate of the three machines recently ordered by the Brooklyn Rapid Transit System from the General Electric Company.

O. de G. Vanderbilt, Jr., president of the Weir Frog Company, Cincinnati, Ohio, is one of those manufacturers whom President Wilson has interviewed on the state of business in this country. In this interview, which occurred on Aug. 5, the President expressed himself as realizing very keenly the extremely bad conditions in the railway supply business, due to the very stringent economy which the railroads of the country have been forced to put into effect on account of the uncertainty as to future legislation affecting them and because of reduced earnings. He feels also that certain basic legislation is necessary before the business interests of the country can be put on a sound basis. As soon as this is in force it will be the attitude of the administration to remove all uncertainty as to future legislation and the position of the administration toward business. As regards the present situation in Europe, the President, according to Mr. Vanderbilt, feels that this country is in an admirable position to withstand the influences which will be brought about by the conflict abroad.

Harry G. D. Nutting has opened an office as a public utility expert and engineer in the First National Bank Building, Milwaukee, Wis. Mr. Nutting's services will be available for valuations, rates, audits, etc., for electric railway, electric light and other public services. After he was graduated from the College of Engineering, University of Illinois, Mr. Nutting did extensive experimental work for Fairbanks-Morse & Company. Later he was engineer for the Wisconsin Railroad Commission, manager of a municipal plant, district superintendent in charge of operation of eighteen towns in Illinois, and electrical engineer for the Government Arsenal at Rock Island. Mr. Nutting has retired from the position of assistant to the president of the Wisconsin Public Service Company, Wisconsin Railway, Light & Power Company and Evanston (Ill.) Railway to establish his own business. He has been retained by these companies as consulting expert. He is also consulting expert for the Berlin (Wis.) Public Service Company in connection with its rate case now pending before the Wisconsin Commission. He has been a contributor to technical literature and read a paper "An Accounting System for a Small Public Utility" at the January, 1914, convention of the Wisconsin Electrical Association. He is also chairman of the committee on extensions and commercial service rules of the association, and the author of a unique formula for determining the advisability of making extensions of distribution systems.

Walter D. Uptegraff, who has recently been elected president of the Union Switch & Signal Company, is, in point of service, one of the oldest men connected with the Westinghouse interests. He was fourteen years old when he became assistant to Howard Sprague, who was secretary of the Westinghouse Air Brake Company. This was in 1880. He quickly attracted the attention of George Westinghouse, the late inventor, who made the young man his private secretary. As Mr. Westinghouse's activities expanded, the responsibilities and duties of Mr. Uptegraff grew in proportion, and in 1896 Mr. Westinghouse showed his confidence in his secretary's ability by giving him his power of attorney to act for him in financial matters. In this capacity Mr. Uptegraff took an active part in the industrial affairs of the Westinghouse interests and was named by the late inventor as one of the three men to act as executor to his estate, the others being H. H. Westinghouse, his brother, and Charles A. Terry, a personal friend and business associate. Mr. Uptegraff, soon after the death of Mr. Westinghouse, was elected vice-president of the Union Switch & Signal Company and the Westinghouse Machine Company. Of both these concerns he had already been a director for some time. Besides his connection with the Switch & Signal Company as president, and the Westinghouse Machine Company as vice-president, he is a director in the Westinghouse Air Brake Company, president of the Pittsburgh Wall Paper Company, New Brighton, Pa., and president of the Defiance Paper Company, Niagara Falls, N. Y.

Sidney G. Johnson, who has been elected a vice-president and director of the General Railway Signal Company, Rochester, N. Y., with headquarters in New York, was born in Eccles, Lancashire, England, in 1874, and entered Harrowgate boarding school when he was about nine years old. At the age of twelve he came to America and went to Swissvale where his father, Henry Johnson, was works manager of the Union Switch & Signal Company. After about a year he went to Rahway, N. J., where the Johnson Railroad Signal Company had been established, and during vacations he worked in the shops and drawing office to acquire a knowledge of the business. He attended a New York preparatory school and for two years after leaving school he worked in the construction gang of the Johnson Signal Company, without pay, in order to learn the business, and then went into the construction forces of the Union Switch & Signal Company for a year. He was then about twenty years old. In 1896 the Standard Railway Signal Company was organized and Mr. Johnson's father was made president. Mr. Johnson was made signal engineer and had charge of the locking and dog sheets, making estimates, etc. When the company moved to Troy, Mr. Johnson went with it, but after the Trojan Car Coupler Company's interests took hold Mr. Johnson's father left the Standard and Mr. Johnson followed him after a few months, and went to the Union Switch & Signal Company in 1899 in the New York office. Shortly thereafter he was made engineer of construction for the Eastern district. Afterwards he was for two years at Swissvale as signal engineer in charge of the estimating department, and then went back to New York and had charge of installing the signal system for the Interborough Rapid Transit Company, New York, and all the other large installations put in at that time. When the Interborough job was finished he was made Eastern manager in charge of sales and construction. About four years ago he was made general sales manager and early in the present year was elected vice-president in charge of sales and engineering with offices in New York.

ADVERTISING LITERATURE

Hess-Bright Manufacturing Company, Philadelphia, Pa., has issued a twenty-eight page pamphlet "Ball Bearings in Machine Tools."

Chicago Pneumatic Tool Company, Chicago, Ill., has issued a sixteen-page booklet in which the company's Class A. O. Giant fuel oil engines are described and illustrated.

Canton Foundry & Machine Company, Canton, Ohio, has issued "Portable Floor Crane and Hoists," a well-printed and attractive booklet so arranged as to be quite explicit in regard to the company's products.

Ohio Brass Company, Mansfield, Ohio, has issued a folding mailing card illustrating the application of the National railroad trolley guard. The company says that more than 100,000 ft. of the guard is in service protecting grade crossings on many prominent roads.

Dielectric Manufacturing Company, St. Louis, Mo., has published "Data on Dependable Insulation," a forty-eight-page booklet. The information in regard to the goodly number of corelated subjects referred to in the publication is made readily available by a very helpful subject index.

Titanium Alloy Manufacturing Company, Niagara Falls, N. Y., has issued Bulletin No. 7 of the series covering comparative tests of standard open-hearth rails and titanium treated open-hearth rails. This bulletin contains microphotographs, sulphur prints and etched sections of rails of both types which characterized previous issues of the bulletin, new tests on three samples of each type being included.

National Tube Company, Pittsburgh, Pa., has reprinted as "National Bulletin No. 10-C" a paper by Dr. William H. Walker on the relative corrosion of iron and steel pipe as found in service. This paper is an abstract of one read before the New England Water Works Association on Dec. 13, 1911. Dr. Walker concludes after an investigation into the relative life of service pipes that on the average there is no difference in the corrosion of iron and steel pipe. The abstract of the paper is accompanied by two discussions on the subject.

Western Electric Company, Chicago, Ill., has issued a very attractive brochure on the use of the telephone for train dispatching. A brief historical account of the telephone development in train operation is given, together with an outline of the reasons why the telephone has been so largely introduced in railroad work. Numerous illustrations are provided to show methods of using telephone selector equipments and details of different types of apparatus which are used, and a number of letters from operating men regarding the use of the telephone in railroad service are reproduced.

S. K. F. Ball Bearing Company, New York, N. Y., has published a catalog "S.K.F. Ball Bearings as Applied to Electric Motors." Applications of this well-known ball bearing have been made to a great variety of motive apparatus, and electric railway men will be particularly interested in the installations made for the Third Avenue Railway, New York. The publication explains the principles of construction of this bearing and contains a number of interesting sectional drawings showing how the bearings may be mounted in alternators, rotary converters, motors and other apparatus used by electric railways.

The Ronald Press Company, New York, N. Y., has issued a 42-page catalog classifying and briefly describing 100 of the best books on accounting, banking, finance, salesmanship, valuations and other general business topics. In selecting them no endeavor has been made to give all business books on any subject or even all the best books, but to give under each heading the names of books generally accepted in business circles as the most reliable, authoritative and generally useful. The pamphlet should be invaluable to electric railway officials who desire to have readily available a carefully compiled list of general business books.

Ray D. Lillibridge, Inc., New York, N. Y., has designed and written for the Titan Storage Battery Company, Newark, N. J., a thirty-two-page booklet dealing with Titan storage batteries for electric vehicles, both trucks and pleasure cars, and for use with self-cranking systems on gasoline automobiles. The chapter headings follow: "The Titan Storage Battery Company: Its Organization and Purposes," "Storage Battery Parts," "Elementary Theory of the Storage Battery," "Titan Pasted Type Plates," "Storage Battery Measurements," "Titan Ignition and Lighting Batteries," "Titan Starting and Lighting Batteries" and "Titan Vehicle Batteries."

Spencer Trask & Company, New York, N. Y., have issued a forty-four-page pamphlet entitled "Knowledge of Investment," written by Charles Lee Scovil. As the author states, the selection of sound investments is largely a matter of education. The pamphlet discusses in a simple manner some of the intricate problems in connection with the buying and transfer of stocks and bonds. It is divided into four chapters, the first of which discusses such points as security of principle, excessive rates of interest, misleading statements, distribution of securities, and mortgages and deeds of trust. The second chapter takes up the difference between coupon and registered bonds, the proper procedure to be followed when bonds are lost and questions in connection with the redemption, payment and delivery of bonds. The last two chapters are devoted to a short analysis of the management of corporations, the rights of stockholders, the institution of a surplus reserve, the value of preferred stocks and the question of diversification of investments. The chief value of this pamphlet lies in its extremely practical discussion of investment points that are too often left unexplained in the standard books on corporation finance.

NEW PUBLICATION

Where and Why Public Ownership Has Failed. By Yves Guyot, editor-in-chief of the *Journal des Economistes*, president of the Sociéte d'Economie Politique of Paris, former vice-president of the Municipal Council of Paris, deputy to the French Parliament and Minister of Public Works, etc. Published by The Macmillan Company, New York. 5½ in. x 8 in. Bound in cloth, 459 pages, $1.50 net.

The question of what State ownership and operation has generally accomplished in the world receives in this volume the most exhaustive treatment that has ever been given to the subject. M. Guyot, statesman, traveler, editor and economist, is able to speak with special authority on the subject because of his former ministerial position in France, which is surpassed by few countries in its activities along government ownership lines. The comprehensive character of the volume is shown by the following topics, which represent only a few of those covered: Municipal activity of the United Kingdom, United States, Germany, Russia, France, Austria-Hungary, Italy, Denmark, Switzerland, the Netherlands, Belgium, Sweden; State operation of railways; State and municipal bookkeeping and finance; private versus public initiative; housing of the working classes; government monopolies; State insurance; State and municipal employment, and graft and corruption.

M. Guyot's evident familiarity with conditions, together with the extremely complete data which he quotes and explains, makes his treatise extraordinarily valuable to the student of government ownership. The chief difficulty in preparing the book seems to have been to make a coherent arrangement of the material, but the author has attained a fair success in this respect. Specific examples and statistics gathered from every available source are brought to bear upon every theoretical argument usually relied upon by the advocates of State ownership, and the result is an uncompromising and effective attack against this principle.

While space will not permit a full review of M. Guyot's book, it may be interesting to note a few of its conclusions. The author firmly believes that when political or administrative bodies, whether states or municipalities, operate, they are regulating themselves. This to his mind is sufficient reason for the suppression of all public trading operations, because it is necessary that there be a distinct separation between the forces of operation and regulation. Industrial operation is inherently adapted to private enterprise, but the only corresponding function of State and municipality is industrial control. Mr. Guyot's treatment of the labor question is particularly comprehensive and the tenor of his remarks can be judged from the following final statement: "The suppression of the political and electoral rights of all employees of states and municipalities is an indispensable consequence of the development of public operation."

In general the author asserts that the propaganda of public ownership has established more firmly than ever before the truth of the following industrial laws: (1) Neither states nor municipalities should attempt tasks especially adapted to individual effort. (2) In the case of utilities in which public interest is general, as railways, water, gas and electric companies, and tramways, there must be a physically and morally responsible body, accountable to the public on the one hand and to the service on the other hand, and protected by contract against the vacillations of public opinion and the extortionate demands of interested groups, whether employees, consumers or patrons. (3) For individuals the watchword should be action; for local and state governments, control.

Vol. XLIV NEW YORK, SATURDAY, AUGUST 22, 1914 No. 8

"FOR THE GOOD OF THE SERVICE"

The finding of the Springfield, Mass., arbitration board, to which reference is made in our news columns last week, is of more than local significance. It places the seal of approval upon the methods of secret inspection utilized by the company, affirms the good faith of the latter's officials in discharging several conductors for irregularities in handling fares, and closes a controversy between the company and the local union which more than once threatened to involve the community in a strike. The proceedings of the board had been under way for many weeks, and vigorous attempts were made at the hearings to discredit the observations of the inspectors assigned to the unpleasant task of running down leaks in the fares collected, but the company's position was upheld, the guilty parties have been discharged from the service and at a meeting of the union immediately following the award, the decision was unanimously accepted. It is cause for congratulation that in this case the arbitration plan worked out satisfactorily, although it is difficult to conceive of any other result after the charges were proved.

SIGNAL LIGHTS AND LINE VOLTAGE

During the investigation of a recent wreck the point was brought out that, with those types of signal which obtain current for their lights from the trolley line, it was possible for the signals to become dimmed and even to go out when the voltage was reduced by the operation of several cars in the block. The possibility of these conditions is, of course, obvious enough, but this is, so far as we know, the first time that it has been suggested as contributory to a wreck. The lamps for such signals are necessarily subject to the same limitations as are those used for the illumination of car interiors, and the problem of maintaining a reasonably constant light in electric railway cars regardless of fluctuations of line voltage has never been satisfactorily solved. Certainly there is no room in a signal installation for a motor-generator or storage-battery outfit at each mast, to make the voltage of the signal lights independent of that impressed upon the line. Apparently the only practical solution of the difficulty would be the use of separate power wires for signal lights that are located far from substations or at other points where abnormal drafts of current are to be expected. It should not be overlooked, however, that there is absolutely no excuse for a collision due to the temporary dimming or obscuring of a signal light. One of the cardinal rules of signal operation is that a lack of indication must be regarded as a stop signal, and the motorman who runs by a signal in which no light is shown is clearly guilty of disregard of duty.

ECONOMIES OF THE SMALL WHEEL

The success of the experiment carried out by the United Railroads of San Francisco, in which standard motors were replaced by those of the so-called "baby" type developed by P. N. Jones of the Pittsburgh Railways two years ago, is a very gratifying demonstration of real economy. The reduction in power consumption effected by the change, which, according to the report published in the ELECTRIC RAILWAY JOURNAL for Aug. 8, will be introduced on 123 cars, was found to amount to about 0.5 kw-hr. per car-mile. This, at a rate of say 1 cent per kilowatt-hour, would equal about $150 per car per year in ordinary city service, a saving in excess of that prophesied in a recommendation of the scheme which was published in these columns just two years ago. The actual reduction in weight was 6220 lb., and this, on the frequently-quoted basis of 5 cents per pound per year, would amount to $310. As the total cost of the new motors and rebuilt small-wheel trucks was $1,682, the return on the investment would be 9 per cent when taken on the first basis and 18 per cent when taken on the second, and as the step heights of the car were reduced by the use of the small wheel to 12½ in. and 10 in. respectively, there is an indirect gain by the change in addition to that which may be expressed in dollars. That the use of the small wheel and the small motor will even pay for the cost of the change on old cars is a most emphatic argument in favor of their universal adoption for new equipment, and it is to be hoped that the action of the United Railroads will help to overcome the unaccountable slowness with which this important new development is being taken up by the electric railways of the country.

TRADE AND INVESTMENT

The point that undoubtedly stands out more than any other in the review of American export conditions published elsewhere in this issue is that trade follows investment. The two great competitors of the United States in South America are England and Germany, in the furtherance of whose trade one of the chief factors has been the enormous investments of capital, especially in railways and mines. The prominence of a few large English and German branch banks, which have lent active assistance to schemes of trade promotion and handling of credits, has also been an asset that must not be underestimated. At present the moment is propitious for the United States to institute moves along these lines. The home absorption of European capital has left most outside countries stranded without sufficient funds to follow out improvements begun and contemplated. It is true that the administration looks upon the American flotation of loans to European belligerents as a breach of that fine, unwavering neutrality we should exhibit, but our governing officials would certainly find cause for gratification if American capital sought South American or other neutral borrowers in order to strengthen our export trade. If branch banks could stir up American capitalists to the opportunities for investment in South American government bonds and private loans, they would well merit institution, to say nothing of the benefit that would accrue from the resulting closer touch with the fluctuating financial and credit conditions of South America. The National City Bank of New York has already taken the initial step along this line under the new currency act permitting the establishment of foreign branches by federal reserve banks. The imitation of this act by a few other large banks, and the placing of the branches in charge of men who not only speak the native language but also have an intimate knowledge of South American conditions and practices, should place our trade on much more than the incidental and occasional basis that has heretofore characterized it.

REGULATION FROM WITHIN

There is food for thought in the suggestion of President Frederic A. Delano of the "Monon" Railroad, and recently appointed by President Wilson a member of the Federal Reserve Board, that the railroads should form a "board of ethics" to keep an eye upon the doings of the railroad companies, exercising over them very much the same sort of espionage and regulation that a clearing-house committee has over the banks within its jurisdiction.

It is easy to find fault with this plan; easy to point out that such a committee would be regarded by the public as merely a whitewashing institution; that it would have no authority to coerce railroad managements; and in general to regard the whole idea as visionary and impracticable, not to say presumptuous, in view of the fact that we are already oversupplied with regulatory bodies instituted by the public and in which the public has more confidence than it would have in a committee of railroad men. Nevertheless the plan has very substantial merits which grow upon the imagination the more they are considered; and the idea is one that would work out as well in respect to electric roads as to steam lines. In fact, so far as its practicability is concerned, it would probably be easier to apply under the aegis of the American Electric Railway Association than under a general movement on the part of the steam roads.

But whether the situation in either industry is such that Mr. Delano's plan will ever be put into effect, it is highly suggestive as to what railroad men can do to better their positions before the public and in the eyes of governmental agencies. This becomes evident as soon as the plan is applied, by way of example, to some very familiar situations in the railroad world. But before doing this let us see how the scheme would work.

The committee on ethics would be constituted, by common consent, of railroad presidents who have established a reputation for ability as executives and for a high sense of their responsibilities to the public as well as to their stockholders. They would not wait until a railroad management was at the bar of a court, a commission or of public opinion; but if the action or prospective action of a railroad management was such as to threaten it eventually with censure and thus to bring down in some degree upon all railroads public or official condemnation, the committee on ethics would look into such a situation, it would make its representations to the management concerned, stating that the action of the road was disapproved by the committee and recommend that the offending management withdraw from the objectionable position or line of action that it had adopted or was contemplating. If objectionable acts or policies were persisted in, the committee on ethics would then be obligated to state to the public that the consensus of railroad opinion, as represented by the committee, disapproved of and disclaimed any responsibility for the acts of the offending road. This is a species of ostracism and disapproval that hardly any road would care to risk.

The weakness of the plan is not that this would be an ineffective remedy against railroad wrongdoing, but that it would be so harsh and destructive that doubts at once arise as to whether a committee could be found that would take such a position. If not, of course, the whole scheme falls to the ground; but it is to be assumed that if the plan were ever adopted at all, it would be adopted in good faith, and that the men who composed a committee such as that under discussion could not be frightened or influenced.

Broadly speaking, the great merit of some such plan as the one suggested by Mr. Delano is that it would work reformation from within; it would anticipate and prevent acts which have brought all railways into public discredit. If it had been in effect for the past few years it would have prevented, in large part, the difficulties through which the New Haven is now going; it would have made impossible some of the acts that have brought the Rock Island into bankruptcy and disgrace, and it would have prevented such humiliation as the Chicago, Milwaukee & St. Paul recently suffered when called to time by the Interstate Commerce Commission for some of that road's bookkeeping methods.

Another outstanding merit of the plan from the railroads' point of view is that it would prevent the many from being punished for the sins of the few. The main difficulty in the way of railroads getting a square deal at the present time is that the general public thinks that all railroad managements are as bad, or almost as bad, as the worst of which the public knows. A sincere, straightforward and effective movement on the part of railroad men themselves to clean house, to cast out evildoers, and among the railroads themselves to put the stamp of disapproval on practices which the general public condemns, would eventually do vastly more to improve the reputation of the railroads than any amount of coercion from without. The fact that a court corrects a railroad wrong does not improve the reputation of the road concerned or of the industry of which it is a part. But if the same correction was fearlessly applied by the roads themselves, beneficial effect upon public opinion would be immediate and more effective for reestablishing the reputation of the railroads than anything else that has yet been proposed.

THE WAR AND THE ELECTRIC RAILWAYS

Thoughtful electric railway men cannot fail to speculate at this time upon the ways in which the frightful slaughter now in progress in Europe is going, sooner and later, to affect their business. They realize instinctively that wholesale destruction must result in hardship to every citizen in the world, so closely knit together are all lines of industry in the fabric of financial credit. The results of the comparatively insignificant Balkan war showed this conclusively. In fact, the industries and people of a single civilized country like ours respond promptly to any success or disaster experienced by any other. Hence, in endeavoring to analyze the possible effects of the war on electric railways, we need to consider mainly what are to be the effects upon our people. In a recent issue of the *Journal of Commerce and Commercial Bulletin,* Prof. E. R. A. Seligman divides these effects into two kinds, immediate and ultimate. The immediate effect upon our industries will be to stimulate them. Business will be good, but prices high and work plentiful. Living expenses will be high, but wages will undoubtedly compensate for this. The ultimate results, according to Professor Seligman, are very difficult to predict. There must come sooner or later a shortage of capital with correspondingly high interest rates and a hampering of industry. To an unknown extent this will tend to neutralize in this country the stimulating effect already mentioned.

Turning now to the electric railway industry, we may attempt to analyze the effect on it of the war according to the principles derived by Professor Seligman, and considering the matter from the standpoints of gross income, operating expenses and the obtaining of new capital for extensions. From what has been said, it would appear that the operating ratio will not be greatly affected. If there should be an increase in industrial activity, the gross income of the railways should reflect this condition, but it would be counterbalanced probably to a considerable extent by increased operating expenses. But it is in connection with the obtaining of new capital for extensions that the electric railway companies will be most greatly affected. The capital requirements of the warring nations, both during the conflict and after its close, will demand cash, which can be secured most easily by a return of the American securities there held. This condition will glut the investment market to such an extent that only those new securities which are most attractive as regards yield can be floated here to advantage.

EFFECT OF WAR ON IMPORTS

While the war in Europe should ultimately result in great benefit to American manufacturers, especially if it is of long duration, some of our industries already have been forced to suspend business and others must soon follow, owing to their inability to obtain the refined materials necessary in their work. For instance, in the timber preservation industry, which has become an important factor in the railway and paving world, 70 per cent of the supply of creosote oils has become discontinued. Practically 80 per cent of the ferromanganese used in the manufacture of manganese steel is imported from England, where it is merely refined, being imported there from mines in Asia Minor. While there is a considerable supply in this country, the price has advanced so that it is almost prohibitive. On the other hand, most of the American ferro-manganese is owned by manufacturers of manganese steel products. According to Franklin K. Lane, Secretary of the Interior, the United States has great stores of manganese which has been largely untouched because it is of somewhat inferior quality. He thinks that to bring this home supply into use means merely the adoption of methods of purification which are known but which hitherto have not been exploited. In the end, therefore, the United States will be able to continue the manufacture of manganese steel without regard to foreign wars or sources of material.

Other important industries affected include the paint manufacturers, who obtain a large quantity of their pigments as well as colors from Europe. Manufacturers of batteries and carbon brushes also will feel the far-reaching effect of this almost world-wide struggle. Undoubtedly, in the end good will come of it. Where there is necessity there usually is an inventor, and American ingenuity is world-famed.

The creosote industry is a salient example of dependence on Europe, where there is little need for it. Although a sufficient quantity of coke-oven and gas-works tar is produced in this country to yield, if distilled, more creosote than present requirements demand, up to this time it has not been looked upon as a profitable manufacturing venture. With our disappearing timber resources American consumers have learned that they must avail themselves of preservatives. Moreover, this demand, along with the interruption of the supply, should be sufficient incentive to the manufacturers already engaged in producing American creosote oil to enlarge their plants. It is possible that the European situation may clear in a short time, but what has already taken place indicates a long struggle for supremacy, which will have a permanent effect on each of the belligerent countries' industrial relations with the rest of the world while tending to make the United States a "self-contained" country.

Manhattan Bridge Three-Cent Line

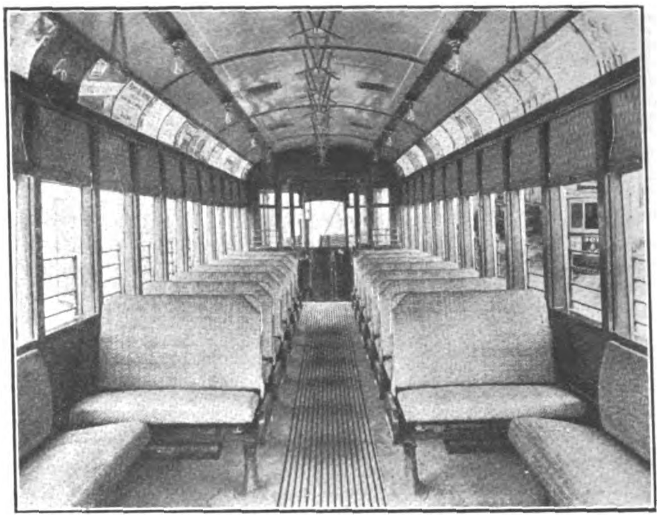
A Description Is Given of the Operation of the Manhattan Bridge Line, with Particular Reference to the Rolling Stock and Carhouse

The Manhattan Bridge Three-Cent Line is the corporate name of the railway which operates over the Manhattan Bridge between the Bowery, New York and Fulton Street, Brooklyn. This company began operation on Sept. 4, 1912, and a brief description of the conditions under which the service was begun was published in the ELECTRIC RAILWAY JOURNAL for Sept. 27, 1912, page 381.

The Manhattan Bridge line now comprises 2 miles of route or 4 miles of single track, exclusive of the tracks in the carhouse. On the Manhattan Bridge the cars are operated over tracks belonging to the city of New York, and on the Flatbush Avenue extension of the bridge into Brooklyn they are operated over the company's tracks jointly with the cars of the Brooklyn & North River Railroad, a corporation formed by the other traction companies of New York and Brooklyn to operate over the bridge and give transfers to the interconnecting lines for a 5-cent fare. The actual amount of non-carhouse track owned by the Manhattan Bridge Three-Cent Line is only 0.88 mile, and this includes four crossings and three crossovers of manganese insert work furnished by the Lorain and the New York Switch & Crossing companies. At present the company is seeking a franchise in Brooklyn to extend the present terminus at Fulton Street about ½ mile via Ashland Place to the Flatbush Avenue terminal of the Long Island Railroad. In the Borough of Manhattan the company is also seeking rights for an extension from the Bowery through Canal Street for about 0.8 mile to the Hudson River in order to give service across town and bring passengers to important ferries and steamship piers.

EARNINGS AND SERVICE

The Manhattan Line operates under a twenty-five-year franchise, paying $4,000 a year to the city out of gross receipts. In February, 1914, the company began to pay its first dividends at the rate of 6 per cent a year. At the present time 14,500 passengers a day are carried, practically all of whom pay fare with tickets purchased at the rate of two for 5 cents. In fact, not more than $8 to $9 a day is received in straight 3-cent fares. During the morning and evening rush hours cars are operated on a two-minute headway; between 10 a.m. and 4 p.m. on a four-minute headway, while the owl schedule calls for the operation of one car on a thirty-minute service from 12 midnight to 5 a.m.



MANHATTAN BRIDGE LINE—INTERIOR OF STANDARD ARCH-ROOF CAR WITH CROSS SEATS

In addition to its practical freedom from maintaining a way department the company has no power station. Energy is purchased from the Edison Electric Illuminating Company, of Brooklyn, at the rate of 1 cent per kw-hr. Should the company use more than 100,000 kw-hr. per month the rate will be reduced to 0.7 cent per kw-hr. The line is fed from the Jay Street substation of the Edison Company, in which the railway has installed one 750-kw General Electric 3300-volt,

sixty-cycle, three-phase rotary converter, transformers, switchboard and other appurtenances.

ROLLING STOCK

The first rolling stock consisted of thirteen longitudinal seat, monitor roof cars, which were originally in the service of the Third Avenue Railway, New York. In August, 1913, however, the company purchased from the Cincinnati Car Company six arch-roof cross-seat cars of modern design, and six like cars were recently ordered from the Southern Car Company. In capacity six of the new cars correspond to eight of the monitor type, so that during the evening rush hours it will be necessary to operate only twelve cars instead of fourteen for the same number of passengers. It is intended gradually to eliminate the original longitudinal seat cars in favor of the new rolling stock which is equipped with the most modern devices for comfort and safety. Illustrations are presented of the first lot of arch-roof cars, from which the lot now under order will differ in

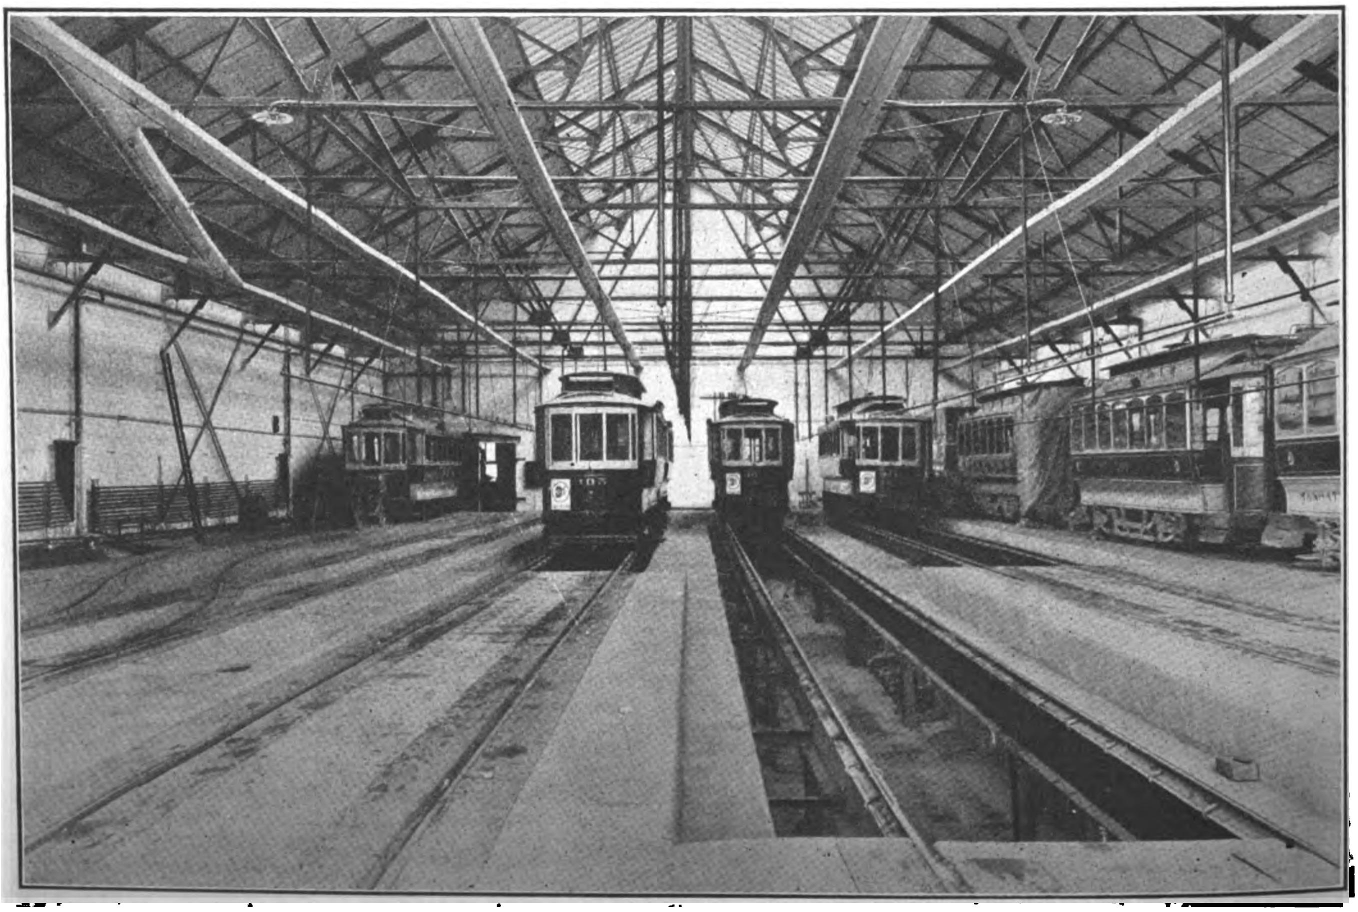
a few particulars. The most important change is that folding steps in connection with four-leaf instead of three-leaf doors will be provided. These cars will be built with a steel underframe and composite body, with interior trim of cherry and with a headlining of Nevasplit. The principal data on the new cars follow:

Seating capacity, forty-eight passengers; weight of car body alone, 16,500 lb.; length over the vestibules, 43 ft. 6½ in.; length of the body, 33 ft. 3 in.; bolster centers, 21 ft.; width over the sills, 8 ft., and height from rail to trolley base, 11 ft. 1¾ in. The trucks will be of Baldwin 54-18 ML-2 design with Symington journal boxes and two Westinghouse 323-A-2 inside-hung motors. The Westinghouse air brakes will be supplemented by "Giant" hand brakes. Other equipment on these cars will consist of Gold heaters, Crouse-Hinds headlights, Lord trolley bases, H.B. wheelguards, Railway Utility ventilators and HL-F control. The wheels for these cars are to be Standard steel drivers and Ramapo special chilled-iron ponies. The longitudinal



MANHATTAN BRIDGE LINE—INTERIOR VIEW OF CARHOUSE, SHOWING LIGHTING, SPRINKLER SYSTEM AND PITS seat cars are equipped with Ramapo 2¼-in. chilled-iron driving wheels which are being changed from ¾-in. to ⅝-in. flanges in order to eliminate chipped flanges.

The remaining rolling stock of the company comprises one Brill sweeper, which served to keep the entire line open during the severe snowstorms last winter.

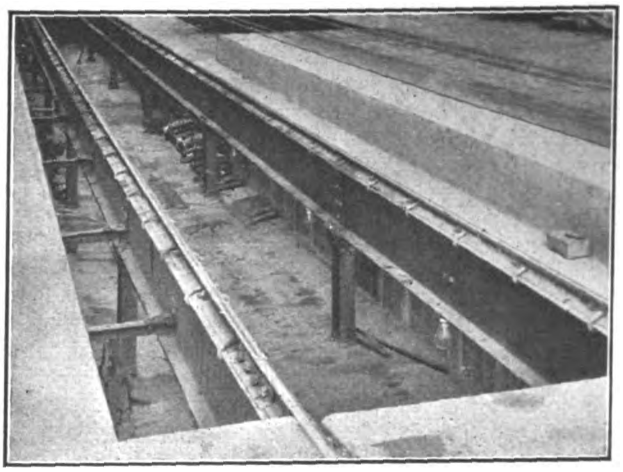
CARHOUSE AND SHOPS

On the east side of Gold Street and 100 ft. north of the intersection of the Flatbush Avenue extension with Myrtle Avenue, the company erected the handsome tile and stucco front carhouse shown in the accompanying illustrations. This structure houses all of the rolling stock and also has a brick-partitioned room at the rear for shop purposes. As shown in the accompanying plan, the entire building is 170 ft. deep x 74 ft. wide, thus permitting the installation of six tracks. Three tracks have pits, one for heavy overhauling and two for inspection.

The piers, pit walls and pit floors and the carhouse floors are of concrete as indicated on the drawings, but the shop floor over the boiler-room is of reinforced concrete. The longitudinal walls are of 12-in. x 12-in. x 12-in. terra cotta blocks built in panels between steel columns and set on reinforced concrete girders. The rear wall, like the shop partition, is of 12-in. brick. These walls are furnished with piers to support the tank installed for the sprinkler system. The roof tiling is of "Bonanza" expanded metal interlocking cement type made by the American Cement Tile Company. This tile is so installed that the whole roof can be taken off, leaving merely the steel framework. A central wired glass skylight, 11 ft. 6 in. wide on each side, extends for the complete length of the car storage section. The effective natural lighting thus obtained is demonstrated by the clear views of the interior.

The neat front of the building has been secured by stuccoing the front girder as illustrated. The stucco finish was made up of one part of Portland cement, two parts of stone and four parts of Peekskill gravel. It was applied only to the panels, the truss outlines being faced with a smooth finish of one part cement and one part fine sand. This front is carried on two ornamental columns which have a molded cap and base.

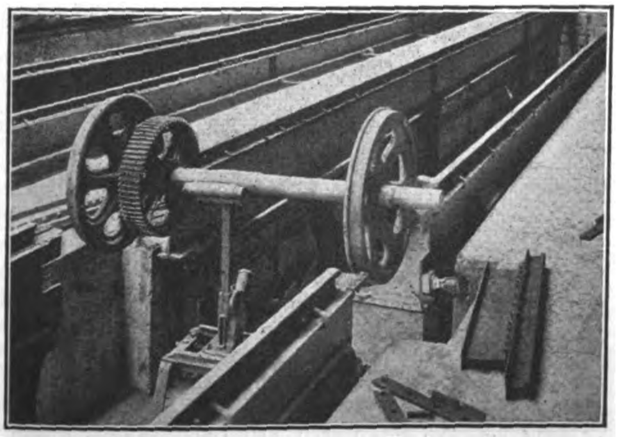
The illustrations of the inspection and overhauling pits show interesting variations from common practice. The main floor of the carhouse is flush with three storage tracks which are bounded by 3-in. x 12-in. spruce timbers on each side of the rails to take up vibrations that would otherwise break the concrete. At the inspection and overhauling tracks, however, the floor, including the devil strips, is dropped 14 in. perpendicularly for the convenience of men working alongside of the cars. At the overhauling tracks the pit walls are set back 14 in. from the pit columns so that a man can stand erect between the columns and the wall to handle any repairs or changes at the sides of the trucks and bodies. All pit tracks are hook-clipped to 18-in. I-beams.



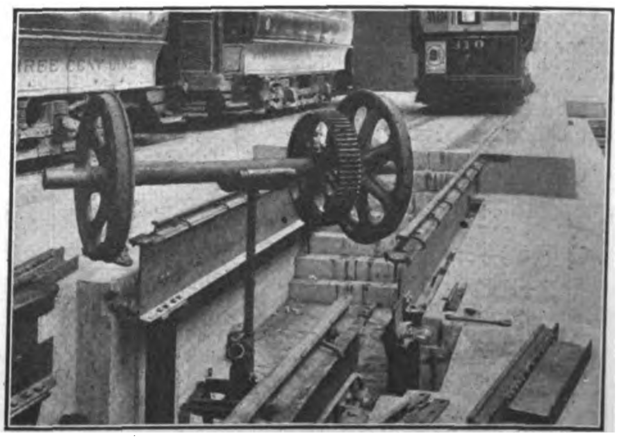
MANHATTAN BRIDGE LINE—OVERHAULING PIT WITH DEPRESSED FLOORS AND STANDING ROOM BETWEEN PIT COLUMNS AND WALLS

Some of the illustrations show the interesting form of wheel pit which was improvised at one of the inspection pits after the carhouse had been in service for some time. The pit was made by constructing an alcove in each wall and by cutting the rails and their I-beam supports, the removable section being reinforced later by smaller intermediate I-beams as indicated. To replace an axle set the car is jacked up, the rails are removed and then the set is lowered to the top of a 10-ton Barrett armature lift, the wheels and axle then being swung around to any convenient angle. A pony set was recently removed and replaced in this way in twenty-nine minutes. The total cost of making the wheel pit was $138.

The carhouse and its contents are protected against fire by Niagara ceiling and aisle sprinklers, furnished by Evans, Almirall & Company. The sprinkler system is connected to an indicator which gives an alarm whenever the water in the tank has reached either the high or the low levels. Hose lines are also installed for fire protection as well as for car washing. The track entrances of the building are supplied with five Wilson steel rolling doors, while approved type Underwriter's fused fire doors are used elsewhere. The fireproof construction of the building, backed by the sprinkler sys-



MANHATTAN BRIDGE LINE—WHEEL PIT AND JACK IN INSPECTION PIT



MANHATTAN BRIDGE LINE—WHEEL PIT, SHOWING REMOVABLE RAIL AND OTHER DETAILS tem, enabled the company to insure the building for only $0.114 and the contents for only $0.336 per $1,000.

The building, including the pits, is steam-heated from a Richardson & Boynton boiler, on the direct system. During the coldest days of the recent severe winter 4 lb. steam pressure was enough to maintain a temperature of 70 deg. Fahr. with closed doors. The boiler is installed in the shop basement, which contains the storage for coal and sand. The latter are delivered from the sidewalk on Prince Street by way of one swinging chute. The sand drier is of the Electric Service Supplies Company's type, with a capacity of 3½ tons for twelve hours.

The carhouse is lighted by means of twelve incandescent clusters hung from the roof trusses, each cluster having five 40-watt lamps with a 20-in. steel reflector. In addition, brackets on each longitudinal wall carry one 40-watt lamp protected by wire guards. There are four similar lamps on the rear wall of the carhouse. The inspection and overhauling pits contain thirteen 25-watt wire-guarded lamps, which are fastened to the bottom flange of the I-beams in staggered relation. Tungsten lamps are also used in the shop. The front of the carhouse is supplied with three five-lamp clusters.

The shop and storeroom located behind the car storage comprises a small smithy, a drill press and a grinder, but the company plans to install a lathe with a 12-ft. bed and 4-ft. swing for simple work. Its wheelwork is done by the Ramapo Iron Works.

The cost of the carhouse, including the steel rolling doors, sprinkler system and other fixed equipment, was $40,000. The building was erected under the supervision of J. M. Johnson, general superintendent, who also had charge of all other construction work in connection with this property.

The Cost of Supplies in Railway Units

S. H. Bennett, auditor Hagerstown (Md.) & Frederick Railway, recently prepared for the information of all employees a schedule which shows the value of a large number of items in terms of the cost of carrying passengers or tons of coal per mile. The list not only relates to supplies in all departments, but also to the equivalents of missed fares, freight losses, personal injury claims, service loss of damaged cars, derailments, broken wires, etc. This instructive schedule and the introduction to it follow:

WHAT IT COSTS!

Did you ever stop to think what carelessness, indifference and neglect cost this company? Do you know that when you lose or throw away a half-used broom, this company has to carry ten passengers 1 mile, or 11.6 tons of coal (inter-line freight) a similar distance, just to get even again, by reason of your act? The table below will tell you what some other items cost this company, figured on the basis of service necessary to offset. Read this carefully.

		Passengers Carried 1 Mile	Tons of Coal Moved 1 Mile
4	Railroad spikes lost or mislaid	2.5	3
1	Spiking hammer handle	6.5	8
¼	Lb. switch rubber	12.5	14.4
1	Dry cell	9	10
1	Trolley rope	20	23.1
1	Trolley feed ear	7.5	9
1	Curve suspension	12.5	14.4
6	Sheets sand paper	1.5	1.6
20	Nuts, ¼ in.	5	5.8
1	Trolley catcher	250	288
1	Car window catch	8	9
6	Lock washers	1.5	1.6
1	Trolley wheel	45	52.2
4	Trolley wheel washers	2	2.3
10	Cotter pins	2.5	3
1	Trolley pole	62.5	72
1	Ball tape	6	6.4
1	Gem lamp	7.5	9
1	lb. waste	4	4.6
1	Tungsten lamp	16	18.4
1	Headlight globe	5	5.8
2	Fuse plugs	3	3.2
1	Pony glass insulator	1.5	1.6
1	Transmission insulator	5	5.8
1	Rail bond	17.5	21
2	Lag bolts, 4 in. x ⅝ in	2	2.3
1	Glass 23 in. x 34 in	26	32
1	Pair Rubber gloves	150	174
1	Fuse—5 amp	8	9.2
1	File, 14 in.	15	17.4
1	Leather register cord	84.5	98
1	Cap badge	30	34.8
1	Air hose gasket	2	2.3
1	Journal box spring	7.5	9
1	Hack saw blade	4	4.6
2	Lbs. nails, 20 d	2.5	3
1	Cash fare missed, 5 cents	2.5	3
1	Cash fare missed, 10 cents	5	5.9
1	Cash fare missed, 25 cents	12.5	14.4
1	Lantern	37.5	43.2
1	Broom—new	20	23.1
1	Broom—half used	10	11.6
2	Postal cards	1	1
1	Stamp—2 cents	1	1
1	Ticket punch	87.5	100
3	Sheets carbon paper	4	4.6
20	Waybills (blank)	3	3.5
20	Conductor's manifests (blank)	3	3.5
30	Conductor's envelopes (blank)	2	2.3
1	Shovel	37.5	43.2
1	Pick	25	29
1	Iron bracket—11 ft	100	115.2
	Overhead line down (simple break)	130	150
	Broken car wheel (cast)	1100	1270
	Switch iron lost	12.5	14.4
	Loss of freight ($5 claim)	250	288
	Loss of freight ($10 claim)	500	576
	Personal injury ($15 claim)	750	864
	Personal injury ($25 claim)	1250	1440
	Personal injury ($50 claim)	2500	2880
	Personal injury ($100 claim)	5000	5760
16	In. of 4/0 trolley	8	9.2
1	Lead pencil	2.5	3
4	Pens	2	2.3
	Labor wasted, 1 hour at 15 cents	7.5	9
	Labor wasted, 1 hour at 20 cents	10	11.6
	Labor wasted, 1 hour at 25 cents	12.5	14.4
1	Oz. rubber bands	7.5	9
1	Phone call (toll), 15 cents	7.5	9
1	Phone call (toll), 30 cents	15	18
1	Armature burned out	2000	2312
	*Derailment—replaced by crew—		
	Time, two men, one-half hour each	8	9
	Time, two men, 1 hour each	16	18
	*Derailment—line car used—		
	Time, four men, one-half hour each	52	60
	Passenger car damaged—		
	Loss of revenue, one day	1500	1728
	Loss of revenue, two days	3000	3456
	Loss of revenue, three days	4500	5184

---

*Damage to car not included.

Production of Pig Iron

The production of all kinds of pig iron in the United States in the first half of 1914, according to the Bureau of Statistics of the American Iron and Steel Institute, amounted to 12,536,094 gross tons, against 14,477,550 tons in the last half of 1913, a decrease of 1,941,456 tons, or more than 13.4 per cent. In the first half of 1913 the output was 16,488,602 tons. Comparing the output in the first half of 1914 with the output in the first half of 1913 shows a decrease of 3,952,508 tons, or more than 23.9 per cent.

The following table gives the production of pig iron in the United States in half-yearly periods for the last ten years:

Years, Gross Tons	First Half	Second Half	Total
1905	11,163,175	11,829,205	22,992,380
1906	12,582,250	12,724,941	25,307,191
1907	13,478,044	12,303,317	25,781,361
1908	6,918,004	9,018,014	15,936,018
1909	11,022,346	14,773,125	25,795,471
1910	14,978,738	12,324,829	27,303,567
1911	11,666,996	11,982,551	23,649,547
1912	14,072,274	15,654,663	29,726,937
1913	16,488,602	14,477,550	30,966,152
1914	12,536,094	....	....

As shown above the maximum production of pig iron in any two half-yearly periods was reached in the twelve months from July 1, 1912, to June 30, 1913, when the output amounted to 32,143,265 tons. The next largest output was in the twelve months of 1913, when 30,966,152 tons were made. The output in the first six months of 1914 was the smallest in any half year since the last half of 1911.

Saving Power on the New York, Westchester & Boston Railway

A Description Is Given of the Methods That Have Reduced the Average Power Consumption of the Cars on This Suburban Line by Nearly 50 Per Cent Through the Use of Recording Watt-Meters and the Establishment of Competitive Records for Motormen

The astonishing economies that become possible through consistent attention to the matter of power consumption by motormen are seldom realized, and as an example of this may be cited the results of a campaign along this line which has been made by the New York, Westchester & Boston Railway. These results show that the power cost on an electric railway may be practically cut in half. As indicated in the accompanying diagram, the power consumption on this road has been reduced approximately from 8 kw-hr. per car mile to 4.5 kw-hr. per car mile. It should be said also that continued instruction of the motormen is expected to result, eventually, in still greater reductions in the amount of power consumed, because the railway officials believe that the best possible results have by no means been accomplished.

On the New York, Westchester & Boston Railway the service is of a typical suburban character. Trains are run at frequent intervals from New York to White Plains and to New Rochelle. On the White Plains line, which is 19.56 miles long, the local trains make twenty-two stops, and the schedule calls for a running time of forty-seven minutes. This gives a schedule speed of 25 m.p.h., with 1.12 stops per mile.

Approximately half of the total number of trains on the White Plains line are run as expresses between Harlem River Station in New York City and Mount Vernon—a distance of 10.33 miles. Over this run three stops are made, and after Mount Vernon is reached the trains continue on to White Plains as locals, making a total of eleven stops over the 19.56 miles of route, the running time being thirty-seven minutes. This gives a schedule speed of 31.7 m.p.h., with 0.56 stop per mile.

Half of the total number of trains on the New Rochelle line also run as expresses over the 10 miles between the Harlem River and Mount Vernon, making three stops as in the case of the White Plains expresses, and the other half of the trains run as locals all the way to New Rochelle. The distance is 12.23 miles and the local trains make eighteen stops, the running time being thirty-four minutes. This gives a schedule speed of 21.6 m.p.h., with 1.47 stops per mile. The express trains on the New Rochelle line make four local stops in addition to the three express stops over the first ten miles of the run, and this makes a total of seven stops in the distance of 12.23 miles, which is covered in twenty-four minutes. The schedule speed for the New Rochelle expresses is therefore 34.6 m.p.h., with 0.57 stop per mile.

In practically all cases the motormen alternate between express trains and local trains, taking an express run one way and returning on a local. These service requirements are not far from the limit of the capacity of the equipment, as the cars are provided with an automatic over-speed control that limits the speed to 56 m.p.h. In fact, the time-card calls for a schedule speed that is close to the absolute upper limit set by the number of stops per mile as generally accepted in engineering practice.

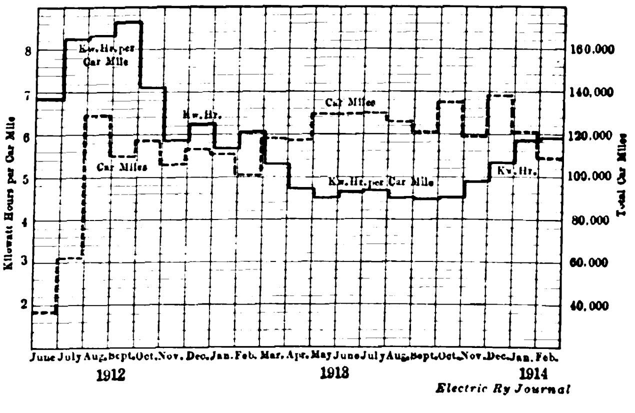
The following table shows comparative figures of theoretical maximum and actual speeds based upon an acceleration of 1.2 m.p.h.p.s. and deceleration during braking of 1.6 m.p.h.p.s., the free running speed being 56 m.p.h.

	Stops per mile		
	0.56	1.12	1.47
Theoretical maximum schedule speed	35 m.p.h.	26 m.p.h.	23 m.p.h
Actual schedule speed:			
New Rochelle expresses	34.6 m.p.h.		
White Plains expresses	31.7 m.p.h.		
New Rochelle locals			21.6 m.p.h.
White Plains locals		25 m.p.h.	

The cars used on this line are 72 ft. long and are equipped with two motors each of 175-hp hourly rating. These are designed to give an acceleration of 1.2 m.p.h.p.s. on level track, and as previously mentioned the running speed is limited to 56 m.p.h. At the present time the road is operating practically without delays of any kind. The cars, completely equipped, weigh about 120,000 lb. and the estimated average passenger load brings the total weight of the car up to about 65 tons under ordinary circumstances.

Record of Reduction in Power Consumption

As shown by the accompanying diagram, the average power consumption increased from about 7 kw-hr. per car mile in June, 1912, to about 8 kw-hr. in July. This increase was caused by the opening of the line to White Plains which occurred in July, 1912. As this line requires all trains to make eight stops in the last 9 miles of the route, the distance operated under local-service conditions was proportionately increased. The effect, therefore, of the express run over the New York end of the line was decreased, raising the average power consumption per car mile. In September, 1912, an increase in power consumption also took place, as shown by the diagram. This was due to the fact that the schedule speed on the New Rochelle division was increased materially with a consequent increase in consumption of power.



WESTCHESTER POWER—UNIT POWER CONSUMPTION SINCE BEGINNING OF OPERATION

During these months no particular attempt was made to reduce power consumption by the motorman, but in October, 1912, a traveling instructor for motormen was employed and the results of this became apparent through the reduction of power consumption to about

7 kw-hr. per car mile during October and to 6 kw-hr. per car mile in November.

In December, 1912, however, a competitive system was introduced by which the power consumption records of all motormen were kept in detail and publicly posted each month, the motormen being held accountable for failure to keep their records close to the minimum consumption. This scheme was placed in active operation in January, 1913, and the results are shown in the diagram by the gradual decrease during the months preceding November, 1913, to a power consumption of about 4.5 kw-hr. per car mile. Based on the weight of approximately 65 tons for a loaded car this is equivalent to 69 watt-hours per ton-mile, the average schedule speed for all classes of service on both divisions being 26.4 m.p.h. with 0.93 stop per mile.

It will be seen that from November, 1913, until February, 1914, a considerable increase in power consumption took place. This is due in part to the fact that the figures as shown include the current used by the lamps, electric heaters and all auxiliary apparatus for the cars. During the month of March of this year the matter was agitated actively, with the result that the power consumption was reduced to an average of 5.35 kw-hr. per car mile for the month, notwithstanding the fact that the cold weather necessitated a liberal use of the car heaters. This consumption, it may be said, is 10 per cent less than that of the preceding month, and now that attention to the matter has been revived it is expected that the records of 1913 will be easily surpassed.

METHOD OF COMPILING MOTORMEN'S RECORDS

The power consumption records are obtained by recording watt-hour meters carried on each car. These watt-hour meters are read by the motorman at the beginning and end of each trip, and the readings are entered in a blank form which is turned in to the chief dispatcher at the end of each day. The form provides spaces for the car numbers, the train numbers, the points between which each of the motormen's runs was made, the reading of the watt-meter at the start and at the finish of each run, the time of starting and of arrival of each train and for the power used during the terminal switching at the end of each run.

As motormen have lay-overs lasting from twenty to thirty minutes after each round trip and the cars are sent back at once, the men generally change cars after each round trip, and, to avoid the possibility of motormen turning in incorrect readings of the watt-meter, the car inspector at the terminal also reads the watt-meter on every car as soon as it arrives and also reads it again when the car is ready to leave for its return trip. At the end of each day the inspectors send their reports to the chief dispatcher, who checks their readings against those of the motormen. Discrepancies between the two sets of readings now seldom occur, but when they are found the motorman involved is promptly advised.

The necessity for taking readings at the end of each trip and at the beginning of the next is due to the fact that while the car is lying in the terminal or being moved around a certain amount of power is consumed by the auxiliaries, by the lights and heaters, and by the switching of the car itself. These terminal power consumptions run from 2 kw-hr. to 4 kw-hr. at each layover, and the power thus used is charged against the inspector and not against the motorman.

The use of watt-meters for establishing power consumption records has been found to be most satisfactory in every respect. The trains on the line are subject at times to delays on account of a drawbridge on the tracks of the New Haven Railroad over which the Westchester cars have to run to reach the Harlem River terminal, and on this account southbound trains are sometimes late at Harlem River through no fault of the motorman. In such cases the fact that the train is late entering the terminal does not affect the motorman's record. No special provision is made for delayed trains, and adherence to schedule is considered of more importance than low power consumption. However, the presence of the watt-meters places a premium upon gradual acceleration and braking, so that the motormen display no tendency to rack the equipment by too rapid starts and stops. As the power used by the car heaters is included in the watt-meter reading it has been found that motormen even take particular care to avoid running the heaters unnecessarily, and in this way a considerable amount of power is saved during the winter season. In fact it is not unusual for motormen to cut out heaters during a trip when the car is heavily loaded and in consequence becomes warmer than necessary, although the adjustment of heaters is ordinarily regulated at the terminals under orders from the chief dispatcher.

The watt-meters are tested about three times a year. At these times the meter is removed from the car and tested on a bench by connecting it across a known resistance through which a certain current is passed. The meter is then replaced, generally on the same car from which it was taken, as a test occupies but a few minutes. The record is entered on a special form which provides space for the meter number, for the number of the car from which it was removed, for the car to which it was applied, for the date of the test and for the percentage of error. In general the error is found to run about 1 per cent above or below the exact figures and in such cases no adjustment is made, although the work of adjustment is a very easy matter. In view of the fact that motormen seldom use any one car for more than one round trip the slight errors in the different meters are averaged up among the various motormen.

METHOD OF REDUCING POWER CONSUMPTION

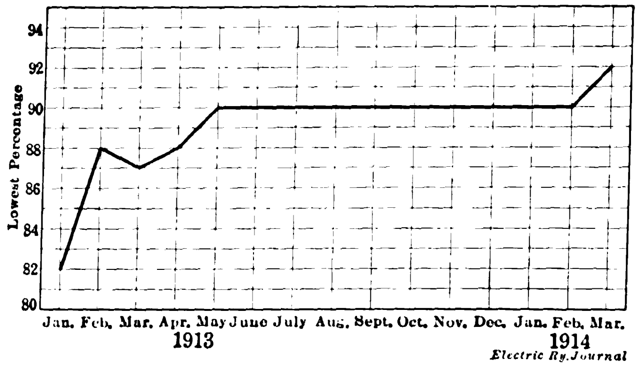
At the present time the operating methods of all motormen are being given special attention. It is customary for the men whose records are poor to be coached by the chief dispatcher, who rides with them and indicates the shutting-off points that are best, under normal conditions, for securing the maximum amount of coasting distance without dropping behind the schedule. No necessity exists for teaching the motormen not to apply power while the brakes are dragging, as the cars are all equipped with an air-brake-and-control interlock which automatically prevents this. The method of making a stop is standardized, as the permanent instructions call for one sufficiently heavy reduction in the train pipe pressure at a predetermined point in advance of a station, the brakes then being graduated off as required to make the stop at the exact point desired. In addition, there are certain places where a motorman can gain thirty or forty seconds on the schedule, and these are pointed out by the chief dispatcher when he is coaching backward motormen. Such places are found between stations where the run can be made in, say, two minutes and thirty seconds, although the time-card naturally has to allow a full three minutes for it. They provide an opportunity for accelerating slowly in case the train is on time, or else for making up time without excessive use of power in case the train happens to be late.

In addition to covering these matters the chief dispatcher, when he rides with motormen, makes a general point of seeing that the trains are not held unduly at the station stops. In fact, it has been found that the rapidity with which bell signals are transmitted makes an important difference in the power consumption. This fact was discovered when some of the conductors were changed around on different runs so that they worked with new motormen. Since their efforts toward reducing the time spent at station stops can affect materially the motormen's records the conductors' names have been included recently with the motormen's names on the competitive list, the same motorman and conductor generally staying together on any given run during the greater part of each month.

The competitive lists show the names of all motormen and the conductors running with them in order of merit, the positions of the men being determined on a percentage basis. These lists until recently have been posted daily in addition to the final monthly reports, as the records for each day can be made up in the chief dispatcher's office by one man in from three to four hours, and can be posted by noon of the day after the records are made. The preparation of the lists includes the work of checking the inspector's reports of meter readings with those turned in by the motormen, together with the calculations involved by reducing the total number of kw-hr. used by each motorman to a basis of kw-hr. per car mile.

However, at the present time these daily lists have been discontinued and the records are now posted to show only the whole month's performance. In this connection it may be said that the bills for power purchased on the New York, Westchester & Boston Railway are based upon the readings obtained from the wattmeters on the cars, the chief dispatcher including, with his records of power used for propelling cars, that used by the inspectors and by the motormen at terminals. He enters all figures in a book, which includes a record of the heaters ordered on or off from the dispatcher's office and remarks as to delays or special conditions.

As an indication of the steady improvement that has followed the efforts of all concerned, the diagram below is shown. This indicates that since the competitive system was introduced in January, 1912, the low men on the list have improved to such an extent that, while the first month of operation under the competitive system indicated a difference of 18 per cent between the lowest man and the highest, the record last month showed a difference of but 8 per cent. This difference between the lowest man and the highest occurred on the New Rochelle branch, while on the White Plains branch the difference was but 7 per cent. The average efficiency of all men during the month of March, 1914, was 95 per cent on the White Plains branch and 97 per cent on the New Rochelle branch, three men being tied for 100 per cent efficiency on the latter line.



WESTCHESTER POWER—DIAGRAM SHOWING IMPROVEMENT OF LOW-RECORD MEN

As before mentioned, the power registered by the watt-meter includes that used by all of the auxiliaries, and these have been found to consume power approximately as follows:

Heaters	23 kw
Main motors in starting	670 kw
Main motors at 40 m.p.h.	192 kw
Transformer	3.5 kw
Air compressor	8.0 kw
Transformer blower	3.0 kw
Motor-generator set	.05 kw

In general the heaters, which are arranged in two groups, take about 15 kw during the winter months, the full consumption of 23 kw applying only to exceptionally cold days. In the summer, of course, no current is used for this purpose. The power used by the transformer is a constant loss, winter and summer, while the air compressor is in use about one-third of the time. The power used by the blower and the motor-generator is constant. In addition to these items there are forty-two 23-watt Mazda lamps which are used at night and also during a short period in each trip while the car is passing through a mile-long tunnel on the route.

Statistics of Steam Railroads

The Interstate Commerce Commission recently issued an abstract of the statistics of steam railroads in the United States for the year ended June 30, 1913, based upon compilations for the twenty-sixth annual statistical report made from the annual returns of carriers having operating revenues over $100,000 and also of railroads owning property operated under lease or other agreement by those carriers. On June 30, 1913, the roads represented 244,418 miles of line, including 11,163 miles used under trackage rights. The aggregate mileage of railroad tracks was 369,580 miles. There were 63,378 locomotives in service, an increase of 2102 over the previous year. The total number of cars was 2,445,508, an increase of 76,566. The total number of employees was 1,815,239, an increase of 115,298, and the total amount of wages and salaries paid during the year was $1,373,830,589.

The par value of the amount of railroad capital outstanding June 30, 1913, was $19,796,125,712, including $8,610,611,327 of stock and $11,185,366,426 of funded debt. The amount of dividends declared during the year was $368,606,327, being equivalent to 6.38 per cent on the dividend-paying stock. The average rate of dividends paid on all stocks outstanding was 4.28 per cent. The investment in road and equipment increased from $15,874,579,926 on June 30, 1912, to $16,351,639,266 on June 30, 1913, or $477,059,640.

The number of passengers carried during the year was 1,033,679,680, corresponding to 994,372,283 for the previous year. The passenger mileage was 34,575,872,980, an increase of 1,536,762,172 over 1912. The average receipt per passenger per mile was 2.008 cents and per ton per mile 0.729 cent. The average operating revenue per train mile was $2.4538 and the average operating expense per train mile $1.7037. The operating ratio was 69.44 per cent. The operating revenues for the year ended June 30, 1913, were $3,125,135,798 and the operating expenses $2,169,968,924, comparing with $2,826,958,366 and $1,959,094,658 in 1912 respectively. The operating revenues per mile of line (including lines operated under trackage rights) averaged $12,873 and the operating expenses $8,939 for the year.

According to information received in Jeffersonville, Ind., from Chester P. Wilson, president of the Interstate Public Service Company, which owns the southern Indiana electric railways and the utilities of New Albany and Jeffersonville, Ind., a pulmotor for the use of the public has been ordered. It will be installed in the Jeffersonville offices of the United Gas & Electric Company and be sent out promptly in response to emergency calls.

Export Trade to South America

Opportunities Offered to American Electric Manufacturers as Result of European War—Transportation Conditions in Individual South American Countries—Interviews with Manufacturers, Shippers and Government Officials Urge Systematic Study to Meet South American Conditions

According to a statement made to a representative of the ELECTRIC RAILWAY JOURNAL by the Acting Secretary of the Department of Commerce, South America is a growing market for electrical machinery and supplies and one in which the United States should have a greater share of business. That this country will be called upon to furnish it more electrical materials will be the natural result of the war now in progress in Europe; but the permanence of this business depends upon a change in certain factors that have worked much to the disadvantage of American manufacturers and exporters. Heretofore, the countries of South America have looked to Europe for capital to develop their natural resources and to utilize their water power in the development of electrical energy. This source of capital is now largely or completely cut off, and the result will be a curtailment of expenditures and the postponement of new enterprises until more auspicious times. The United States will profit, no doubt, through their necessity of getting supplies, but it should be borne in mind that purchases by South American countries will be limited to urgent needs.

The chief factor against the sale of American equipment and supplies is the fact that the source of capital for South American enterprises and the nationality of the engineers have largely determined where they shall be purchased. A project with German financial backing, carried out under the supervision of German engineers, is practically certain to use German materials, as far as they are available at competitive prices. In fact, in recent years it has become a practice for banks furnishing the money for such enterprises to stipulate the use of materials from the country in which the banks are located. Investment of United States capital in South America is small as compared with the amounts invested there by England, Germany and France. Hence, manufacturers of electrical machinery and supplies in this country have been at a great disadvantage. Conditions in the electrical field are similar to those obtaining in the railway field.

The one country that seems to have been most successful in combining the efforts of bankers and manufacturers toward the increase of business and export trade is Germany. Back of the greatest electrical concern in Germany is a group of banks that furthers the interests of the combine in foreign countries by furnishing money for the development of various enterprises. The net result is that the money furnished by these banks is spent largely in the purchase of goods from the manufacturing companies with which they are allied.

It must be borne in mind, however, that the financial resources of the great European nations are being rapidly exhausted by war. It is fair to assume that it will be many years before they recover from its effects. In the meantime they will have great industrial problems to solve at home, and investments in far off South America will be far less attractive to their citizens than they have been in the past.

The time seems ripe, therefore: First, for a more liberal investment of United States capital in South American development; second, for a very considerable business in ordinary electrical supplies and in the equipment necessary for the completion of projects already begun, and, third, for demonstrating to the people of South America the satisfactory character of American electrical apparatus. In common with other American-made goods, apparatus of this kind has been misrepresented by foreign competitors and we ought to make the most of our opportunity to demonstrate their excellence. To take the fullest advantage of the present situation prompt and vigorous action on the part of our manufacturers is needed.

POINTS FOR AMERICAN EXPORTERS

According to a study of the South American export trade just made by Otto Wilson for the United States Bureau of Foreign and Domestic Commerce, poor packing, poor marking, failure to send goods as ordered, an insistence on cash with order or at least cash with documents, and the sending of catalogs and correspondence in English instead of Spanish or Portuguese are charges made against American exporters. Considerable improvement in these matters has been noted in the last few years, however, indicating that Americans are paying closer attention to South American requirements. It is important to remember that the ordinary credit terms of ninety days are usually insisted on even by houses that do not need the credit, for they regard a refusal of the usual terms granted by Europeans as a reflection on their integrity. Besides printing catalogs in native language, American exporters should be careful to use metric weights and measures instead of English and American standards.

As Mr. Wilson points out, numerous opportunities exist in South America for the extension of electric light and electric railway trade. For example, the number of electrical enterprises in Argentina in 1910 was fifty-six, with 2402 employees. One of the most noticeable features of Buenos Aires is its extensive street railway service, in which German and American electrical apparatus is used.

The character of goods demanded in Bolivia may be judged from the following quotation from the report of an American diplomatic official: "Bolivia needs electrical goods and supplies for railway construction, and when Bolivia has real opportunities to become acquainted with what the United States can supply sales will not be lacking. Nearly every city of size in Bolivia has an electric light plant, but the supplies therefor have been procured chiefly in Germany and France. American manufacturers could probably overcome this competition if they could meet the prices of the competitors, because American goods in this line are generally regarded as of superior quality."

The American manufacturers have become more and more interested in Brazilian markets in late years and in 1912 the United States passed Germany, the chief competitor, in the importation of electrical machinery to Brazil. In electrical work, especially railways, electric light and power systems, etc., American products compete as a rule on equal terms with those from Europe and have become very prominent. The mountainous nature of the country to the south makes possible the wide use of hydroelectric power. The market for waterwheels, turbines, electric motors, cables and everything connected with the generating and transmitting of power, says Mr. Wilson, is sure to be steady and growing.

As for Chile, it may be expected that hydroelectric machinery will be in constant demand in view of the mountainous nature of the country and the numerous rivers. Germany has a long lead in supplying electrical machinery, especially for electrical enterprises, but there is no reason why a great part of this trade should not come to the United States with the advantage of shipping distances this country will enjoy at the completion of the Panama Canal.

Mr. Wilson states that a demand is expected for electrical supplies in Peru. In Montevideo, the capital of Uruguay, there are two systems of electric tramways, besides a line of horse cars. One of the electric tramways is British and the other German, the former carrying about 40,000,000 passengers a year. There are few electric railways in Peru, and these mostly run out from Lima. In import trade to Peru the United States occupies a very favorable position. The trade conditions and tramway development in other countries are also mentioned.

INTERVIEW WITH MR. OUDIN

M. A. Oudin, manager of the foreign department of the General Electric Company, and member of the National Foreign Trade Council, in an interview with a representative of the ELECTRIC RAILWAY JOURNAL, declared that the opportunity before American manufacturers as a result of the curtailment of European production is one that concerns all industries. He was glad to give his ideas because he regards it as a patriotic duty to do all that can be done to remove the obstacles which have hampered the growth of export business. The problem is larger than the interest of a single company or of a single industry. The electrical business should share in the stimulation which our exports are bound to experience in the immediate future. The question which most concerns electrical manufacturers is how this trade may be acquired on a profitable and permanent basis.

Mr. Oudin pointed out, however, that while the stoppage of European supplies of all kinds is a factor favorable to a great extension of American trade, there are two adverse factors having an important bearing upon the magnitude of the trade that may be obtained. The first is the financial disturbance which has existed throughout the world for over a year; this economic depression, particularly in South America, has been made much worse by the war in Europe. The second adverse factor, which is of a temporary character, is the dislocation of transportation facilities which now exists.

The two important markets for our goods in South America, namely Brazil and Argentina, have been passing through a financial crisis of the first order. The inability on the part of the former country to obtain the loan which was needed so greatly has accentuated an already difficult situation. This loan was almost closed when the war broke out. The withholding of European funds for the further development of public and private enterprises in both countries will cause a cessation of engineering and other work there. It should also be remembered, Mr. Oudin added, that the purchasing power of South American countries particularly has been greatly lessened by the partial closing of European markets to their products. This undoubtful lessening of exports from South America with the result mentioned will be offset more or less by an increase in prices. For the reasons given above, at least reasonable caution should be exercised in the extension of credits.

Interruption of the shipping facilities in this country would have a most serious effect upon home affairs if prolonged, and a continuation of this situation would go a long way toward nullifying the favorable opportunities for furthering our export trade. But already the situation is much improved. Mr. Oudin expressed pleasure that so far as it has the power Congress has relieved the situation by passing a law admitting under certain conditions foreign vessels to American registry and removing the regulations heretofore applying to our merchant marine which made the employment of ships in our foreign trade an unprofitable venture.

The essential elements in the exploitation of manufactures abroad, Mr. Oudin declared, are representation, price and quality. If the small manufacturer cannot afford to have his own office abroad he must have recourse either to agents as a medium through which his goods may be sold or to commission houses or brokers in his own country. Another method by which the small manufacturer can acquire a market is through association with other manufacturers of allied lines. What we need most abroad is American business houses. Until our small manufacturer can sell his goods through such concerns established abroad, his business is bound to be more or less intermittent, for it is obvious that he cannot depend upon the permanency of an agency arrangement with a European firm, nor can he secure the highest effectiveness from an arrangement with a native concern.

As to prices, the prices of American manufacturers are higher ordinarily than those of European competitors. This is due to the higher costs of labor which prevail in this country. The influence of the war will operate in the direction of overcoming that handicap because it will have a tendency to increase labor costs in Europe. As to quality, American goods in general are superior to those of European countries, especially of Germany, but they are not always sufficiently superior to overcome the differences in cost. In many lines American engineering is recognized as superior to European engineering, but this advantage is not regarded as sufficiently great in some countries to overcome differences in cost; particularly is this true in countries whose financial resources are limited and where the people are more concerned about low first cost than about future maintenance and operating expenses.

Already two factors have been mentioned prominently as bound to influence our foreign trade favorably. One is the increase in our merchant marine, and the other the establishment of American banks abroad. Mr. Oudin believes that it is easy to overestimate the influence of these activities in creating new business. The establishment of American banks abroad will have certain advantages which must affect our foreign trade favorably, but is not likely to have as great an influence upon it as the other factors which have been mentioned. If American banks established abroad could have branches in different parts of the country there is no doubt that such banks would assist to a very large extent in securing more reliable information as to the financial standing of prospective purchasers than it is possible to get under the present banking conditions. The great potential influence cited by Mr. Oudin in connection with our foreign business in the establishment of banks in foreign countries is that thereby American capital will be encouraged to seek investment abroad. If American banks abroad could arouse American investors to the opportunities for investment in these foreign countries, both in issues of government bonds and the loans of private enterprises, their usefulness because of this consideration alone would be established beyond any question.

INTERVIEW WITH VICE-CONSUL OF BRAZIL

The vice-consul for Brazil at New York, who is thoroughly familiar with business and political conditions in Brazil and has gained the American viewpoint by residence here of more than twenty years, said to a representative of the ELECTRIC RAILWAY JOURNAL that the United States had for some time gradually been becoming a factor in the commerce and trade of Brazil and that the war in Europe would work greatly to the advantage of Americans if they were judicious in the use of the opportunity now presented to them. In the past Brazilian projects had been financed very largely in England and Germany, but this did not indicate any prejudice on the part of native Brazilians or the government. As an instance of this he referred to the joint English and American traction promotion in Sao Paulo and Rio de Janeiro. While practically all the large public utility projects had been floated abroad, the small ones were being taken care of by the local Brazilian capital and were officered by natives, many of whom had been educated in the United States.

The vice-consul said that the machinery in use in the industries of Brazil was largely English and German, but this was mostly a matter of expediency, those engaged in promoting any given work giving preference to the machinery made in their home country. For instance, practically all mining machinery was of English manufacture, the mine promoters and engineers engaged in Brazil being English. That there was absolutely no prejudice against American machinery was attested by the fact that much American machinery was in use in Brazil although few Americans were engaged in industry there. On the whole, American machinery in use in Brazil had been found very satisfactory compared with that from Europe. For some time past most of the electrical students from Brazil had studied in the United States, and this in itself would likely result in advantage to the American manufacturers on account of the familiarity of such men with American machines and American manufacturers when they entered active work.

Transportation between the United States and Brazil was inferior in many ways to that between Brazil and the European countries. This has naturally told in favor of Europe. This gentleman was enthusiastic in regard to the possibilities for America in developing coal trade with Brazil. He said that in this trade America would have to contend with the already well established English market, but felt that Americans could profit by turning their attention to such trade.

The vice-consul said a great deal of discretion would have to be used by Americans seeking business in Brazil. With the European market unsettled Brazilians would naturally turn toward America, but the American who showed any disposition toward being avaricious or exacted extortionate prices could not hope to keep the Brazilian trade after the settlement of the European conflict. He said that the Brazilians feel that the stoppage of commerce to Europe means an excess of American manufactures and that the excuse could not be advanced that increased demand from other sources had caused a natural increase in prices. The present unsettled conditions in the United States would seem to indicate that prices could be made to Brazilian ports low enough to compensate for the high freight and the insurance. On the other hand, those Americans who dealt with Brazilians judiciously would probably find a permanent market for their wares in Brazil irrespective of the outcome of the war. It would be advisable for Americans who hope to do business in Brazil to arrange to extend to their Brazilian customers the same credit terms that have been accorded Brazil in the past by European firms. Americans should try to anticipate the Brazilian need and cater to the Brazilian taste. The vice-consul gave the value of the imports of machinery into Brazil in 1911 as $28,660,000 and in 1912 as $36,292,000. He said that in 1913 Brazil imported from the United States $3,000,000 of electrical supplies, $1,074,000 of iron goods, $800,000 worth of coal, $167,000 of zinc and approximately $700,000 of lubricating oils. The value of the imports of rails in 1913 was approximately $1,500,000, while that of locomotives for 1913 was $1,600,000.

INTERVIEW WITH MR. TRIPP

Guy E. Tripp, chairman of the board of directors of the Westinghouse Electric & Manufacturing Company, returned from Europe on the steamship *Celtic* on Aug. 15. When war was declared by Germany on France Mr. Tripp was in Paris. Foreigners were ordered to leave the country and he went to London. Although his voyage was taken for business and pleasure combined, it was interrupted in France, and for that reason he did not have much opportunity of observing commercial conditions abroad. He thinks that it is impossible to form any conclusive opinion at this time as to the effect of the war on ultimate commercial conditions in Europe. Both the French and the Austrian subsidiary Westinghouse factories have been closed. It was necessary to do this because the operatives left to go to war. The plant in Italy is still in operation. The plant at Manchester, England, is operating on full time. Up to the time that Mr. Tripp left England comparatively few of the men at the Manchester plant had left to go to war.

The export business of the Westinghouse company to South America, Japan and China is handled from this country, and Mr. Tripp mentioned the opportunity presented to American manufacturers to meet the needs of consumers in those countries. In order that trading relations may be developed the principal necessity is to establish banking facilities and, following the practice of German manufacturers, to give buyers longer time for payment. The German manufacturers have been borrowers at low rates and were satisfied with small margins of profit. There is no reason, Mr. Tripp believes, why this country should not follow the practices to which South American buyers have been accustomed.

Mr. Tripp believes that as a result of the present situation this country should become a creditor nation instead of remaining a debtor nation. By the development of a larger export business it can get a steadier load for factories and reduce the overhead cost. The great bugbear which confronts manufacturers in this country is the fluctuation in the volume of business. When the business is stretched over a larger area the fluctuation in volume is likely to be less.

INTERVIEW WITH SENOR NAON

In an interview Señor Ramulo S. Naon, Argentine Ambassador to the United States and one of the recent A-B-C mediators in the Mexican trouble, expressed to a representative of the ELECTRIC RAILWAY JOURNAL the hope that American manufacturers would respond promptly to the commercial needs of his country. As evidence of her desire to trade with us he cited the emergency foreign exchange system which his government had established. He warned American manufacturers, however, that South American trade customs must be studied if headway is to be made. It is almost useless to expect any inquiries from pamphlets delivered by mail. Traveling salesmen equipped with letters of introduction and other credentials and familiar with the South American ways and manners, are necessary if goods are to be sold.

Engineers and engineering contractors should also realize that bids are generally delivered in person by a representative and not by mail, as is customary in the United States. In advertising for bids on construction work the interval of time given before opening proposals is often as long as six months, so as to enable representatives of foreign firms to forward specifications and other data to the home office and allow adequate time for the preparation of careful estimates.

Extensive commercial relations depend on good banking facilities, a fact that has been readily appreciated by the Argentine Senate and Chamber of Deputies. On Aug. 11 a law was passed empowering the executive to receive and deposit in the Argentine legations sealed gold from commercial and banking houses. The treasury department upon receipt of telegraphic advice from a legation will then issue a bond in favor of the Caja de Conversion for the amount of gold deposited. Against the delivery of this bond through the Banco de la Nacion Argentina, the Caja de Conversion will deliver to the same bank the equivalent in paper pesos, to be credited to the proper person. The Argentine government, Señor Naon said, has thus made foreign exchange easy. It is for Americans to supply the ships. They can enter the South American trade in force assured that they will be most cordially received by the nations to the south.

INTERVIEW WITH W. E. PEARSON

W. E. Pearson, of the Pearson Engineering Corporation, New York, believes that there is an excellent market for American goods in South America, if the manufacturers in this country will pay attention to the requirements of South American buyers. The Pearson Engineering Corporation is interested in a number of South American properties, as it is the purchasing agent of the Brazilian Traction Light & Power Company, which owns the Rio de Janeiro Tramway, Light & Power Company, the Sao Paulo Tramway, Light & Power Company, and the Sao Paulo Electric Company. Of these properties, that at Rio de Janeiro is the largest, the tramway department operating about 270 miles of track, 342 passenger cars and 202 freight cars. The car mileage made last year was 24,830,760 and the passengers carried 195,783,634. This same company had a lighting load last year of 683,937 incandescent lamps, 10,821 arc lamps and 63,539 hp of motors. The company also controls the gas business in Rio de Janeiro, and the telephone business there and in several neighboring cities. The Sao Paulo tramway company has 141 miles of track, 386 passenger cars and 84 freight cars, and the gross receipts from its light and power business were more than $5,000,000. The Sao Paulo Electric Company supplies power to the Tramway, Light & Power Company. Dr. Pearson, president of the Brazilian Traction, Light & Power Company, is also interested in the Bahia Tramway Company in Brazil. This system is now operated from London and its purchases are not conducted by the Pearson Engineering Corporation.

Mr. Pearson said that since the period of hostilities had begun in Europe there had been a large increase in freight rates from New York to Brazilian ports, namely, from about $8 a ton to about $21 a ton for electrical materials. This increase has been practically uniform on all of the fifteen or sixteen transportation lines between New York and South America, all of which, except one, are owned by foreign interests. He believed this was to be temporary only. Continuing he said:

"One question which the manufacturers in this country will have to take up in developing the sale of electric apparatus in South America is that of credits. Most South American purchasers have received long credits from Europe, especially from Germany. These credits are usually cared for by financial institutions, working in conjunction with the manufacturers, so that the latter receive their pay promptly. The usual terms of payment are sixty and ninety days, but these are often extended, one case, for example, being a gas plant in one of the cities of Brazil costing about $1,000,000, for which payment was not demanded for three years. These long credits are necessary owing to the recent development of the country, and are asked especially by purchasers in smaller towns. This is a matter in which the bankers in this country can render great assistance to American manufacturers.

"Another important matter is that of good packing for all shipments on account of the many times a package has to be trans-shipped. The large American manufacturers of electrical apparatus, like the General Electric, Westinghouse and Western Electric, understand the necessity of this, and their shipments rarely are received in bad condition. It would seem as if they had learned how to pack lamps, for instance, by trying different ways and then throwing the packages out of the window until one kind of packing has been devised which would stand such treatment. But most American manufacturers have not yet learned how to pack their goods for South American delivery. Thus, in a shipment of glass which we received some time ago from an American manufacturer, 99 per cent of the glass was broken. We could get no redress from either the shipper or the shipping company. I know of only one manufacturer of gas stoves that can pack these goods so that they will be delivered in Brazil in good condition.

"Most of the electric apparatus used by our properties in Rio de Janeiro and Sao Paulo comes from the United States. We buy practically everything in America except repair parts for apparatus originally built in Europe. The cars are built locally, because Brazilian wood withstands the climate better, but all the car trimmings and other metal parts, such as trucks and steel underframes, come from the United States. Of our coal we buy about 75 per cent in England, the rest in the United States. The English coal is not better, but England can offer lower freight rates, because the steamers get the return freight.

"Outside of Rio de Janeiro and Sao Paulo the principal electric railway properties in Brazil are at Bahia, Campinas and Santos. These originally were installed by German capitalists and necessarily buy most of their repair material in Europe. In the smaller cities in Brazil which have street railways, mules are used in many cases."

INTERVIEW WITH MR. CHILSON OF THE J. G. WHITE ENGINEERING CORPORATION

According to E. N. Chilson, purchasing agent The J. G. White Engineering Corporation, New York, 75 per cent of South American imports in transportation materials, power house apparatus, coffee machinery and agricultural machinery is either manufactured by Europe or sold by Europe. The countries mostly concerned in this are Argentina, Brazil, Chile and Venezuela. The credits of the South American consumers or dealers have been so long established in Europe that it is only natural that they should buy there what goods they need.

The usual credit given is ninety days' draft through European markets. This gives the purchaser an opportunity to place an order and have it delivered to him for consumption before actual payment. On the other hand, the American method provides for spot cash or a three days' sight draft, thereby making the purchaser assume all of the risks. If we are to establish trade with South America on a firm basis, however, we must bring about an amicable credit adjustment so that South Americans can come direct to our markets, get good shipments and start actual disposition of goods before payment is made.

A Brazilian paper dealer recently endeavored to buy 10,000 tons of paper through New York brokers. He had formerly paid German exporters by a ninety days' draft, but New York brokers refused to sell except on a confirmed bankers' credit or a gold basis. If some of the American paper companies had had agents here in Rio de Janeiro to look up the customer's credit, it should have been possible to make a satisfactory adjustment instead of losing this customer's trade.

It has been suggested that a sufficient trade balance be established in New York to allow the South Americans to purchase all goods needed. In Mr. Chilson's belief, were this condition once established, Europe would not be able to take trade back after the war. It is the prevailing opinion here that if the war continued from twelve to eighteen months, industrial and agricultural pursuits in Germany, England, France and Russia will be so demoralized that it will take an equal or longer time for these countries to recuperate. Hence, American manufacturers will probably have a period of about three years in which to place themselves on a firm basis with South American consumers. The countries engaged in South American trade were ranked before the war in regard to the volume of trade as follows: (1) England, (2) Germany, (3) France, (4) Belgium and (5) United States. If American manufacturers make the proper use of their opportunities America should secure a firm position much higher in the list.

In regard to proper transportation facilities, Mr. Chilson said that the Brazilian government has a government-owned steamship line, the Lloyd Brazileiro, of 100 vessels, and with the trade balances coming our way, the line will no doubt be placed in the American trade. Ineed, Ambassador Edwin V. Morgan has already cabled from Rio de Janeiro that the Minister of Finance of Brazil is arranging to dispatch to the United States five vessels of this line with consignments of coffee from Santos and Rio de Janeiro and rubber from Para, and these vessels are to bring back cargoes of prime necessities.

American manufacturers, however, must take a long-sighted view of the present situation and not endeavor to make abnormal profits by boosting prices. South American manufacturers would feel that they were being fleeced on account of the almost compulsory trading with this country, and after the war they would turn back instantly to their former producers. The rail market, for instance, has been quiet for the last two or three years. Orders from South American trade could be easily handled by American steel manufacturers and would only serve to make up for part of the present depression in trade here. South American consumers are well aware of this fact, and any attempt to run up the price through a falsification of the facts of present demand and supply would only result in irretrievably losing the South American market when the present war restrictions on European products are removed.

INTERVIEW WITH MR. SCOTT OF W. R. GRACE & COMPANY

A. L. Scott, assistant manager W. R. Grace & Company, New York, in an interview with a representative of the ELECTRIC RAILWAY JOURNAL, declared that the increase in freight rates that has been evidenced since the beginning of hostilities in Europe had averaged 50 per cent, although some advances have ranged as high as 100 per cent or more. His own company has not yet put any increase into effect, although it expects to make soon an increase of from 15 to 20 per cent. Mr. Scott did not believe that American manufacturers would be so short-sighted as unnecessarily to increase prices to South American purchasers, and he was inclined to believe that such an assertion made by some was due to a lack of understanding concerning the effect of the increased freight rates caused by the war. The extra war rate has necessitated increased freight rates, which have caused seemingly greater increases in the prices of goods carried. For example, a freight rate of $10 per ton increased according to the average figure of 50 per cent, would amount to $15, or 12 cents a cubic foot. This might cover an article which may be worth only 50 cents a cubic foot, causing an increase of nearly 25 per cent in the quoted price of the article.

W. R. Grace & Company is one of the firms known as banking and shipping lines. According to Mr. Scott, this means that the company in transmitting its shipping to western South American ports has become familiar with the credit conditions of the best-known merchants in these localities. The company is desirous to be of service to shippers by means of any information that is at hand or obtainable as to the responsibility of prospective clients and by taking care of the banking transactions between the shippers and the buyers. Mr. Scott believed, however, that efficacious as this method may be, the up-to-date manufacturer is not relieved from the responsibility of taking active steps himself for the development of trade in the field.

The problem is not so serious for the extensively organized companies, for these can afford to have traveling salesmen, and also local representatives in the South American countries who can act as bureaus for getting information concerning South American buyers and also serve to place American products before the eyes of these buyers. For the smaller companies who cannot afford a traveling agent or a representative, it would be highly desirable to establish a combined representative for five or six companies of allied character. American banks can also participate in commerce with South America by establishing branch banks, as the National City Bank of New York has done. The credit that would usually have to be given to South American purchasers will not be less than ninety days, and on contracts up to large amounts the time may extend as long as two years.

A vital point for American manufacturers to realize is that American goods need to be only seriously exploited in South America, under the proper knowledge and appreciation of South American conditions, in order to have a substantial and lasting export trade from America with these companies built up. It is not difficult to show the inhabitants of the West Coast the superiority of American goods at the same price. While the temperament of the South American may lead him to consider the first cost more than the question of maintenance and operating life, the only thing needed in order to rectify this is to educate him in regard to approved American ideas on such subjects. In order to do this it is necessary that catalogs and prospectuses should be written by men who have a knowledge of conditions in South America and men who are able to tell their story to their prospective buyers in the latters' native language.

INTERVIEW WITH MR. FLINT

Charles R. Flint, of Flint & Company, New York, has stated to a representative of the ELECTRIC RAILWAY JOURNAL that he believed that the placing of foreign ships under American registry during war times, which is forbidden by the terms of the Declaration of London, can undoubtedly be overcome by some means and that the danger of seizure by the British of former German liners flying our flag and vice versa can be obviated. In Mr. Flint's opinion, there is now a remarkable opportunity to enlarge the merchant marine of the United States and give to American manufacturers the opportunity to send their products to neutral markets under the American flag. His idea is that conditions under which American corporations can buy and run foreign-built vessels should be relieved from embarrassing restrictions. In order to bring this about American corporations should have the right to compensate foreign shipbuilders in bonds and other obligations of American corporations and should not be compelled to pay cash in order to effect American ownership. There should not be any reason why purchase should not be made of ships of any age, nor should there be any uncomfortable restrictions as to the character of the crews which might be employed.

According to Mr. Flint, the outcome of the present opportunity depends entirely upon the industry with which American manufacturers take advantage of the opening afforded them. The financial depression that has been existing in certain South American countries, notably Brazil and Argentina, will undoubtedly prove slightly embarrassing to the immediate institution of increased trade relations between these countries and the United States, but this condition cannot be at all permanent. While the present administration has taken a position against the making of loans by American capitalists to belligerent buyers, as exemplified by the recent turning down of the proposed French loan, it is Mr. Flint's opinion that the administration officials of the country would be gratified to see our export trade increase as a result of loans to neutral countries.

Electric Construction Locomotives

In connection with the construction of the 3-mile Mt. Royal tunnel of the Canadian Northern Railway at Montreal, six small storage-battery locomotives are being used to haul 175 tunnel dirt cars. The storage batteries are carried on trail cars, there being two batteries for each locomotive. These locomotives were originally operated by gasoline. It was hoped that the carbon monoxide in the exhaust could be changed to dioxide by passing over lime, but this was only partly successful. The fumes finally became so objectionable that 110-volt electric motors were substituted for the engines, the locomotive gearing being left practically without change, and the trail car with a sixty-cell storage battery being added to each locomotive to supply the current.

Recently, since the hauls have become longer and a larger tunnel cross-section has been available so that a trolley wire could be used, these same locomotives have undergone still another change. A trolley pole and another 110-volt motor have been added, the two motors operating in series and being supplied with 220-volt power from the trolley wire.

In addition to these six gasoline-storage-battery-trolley locomotives there are one 6-ton and two 10-ton 250-volt General Electric trolley locomotives, and two 7-ton trolley locomotives built in the job machine shop.

First Valuation Regulations

The Interstate Commerce Commission recently promulgated the first regulations to govern the valuation of the physical properties of railroads subject to the Interstate Commerce Act. The commission orders that every common carrier shall in each year, beginning with the year 1914, take an inventory of all extensions and improvements or other changes in physical property and report to the commission. The regulations follow:

1. Intent.—In order that the Interstate Commerce Commission may investigate, ascertain, report, and record the value of property of every common carrier, subject to the provisions of the act to regulate commerce, as such property may be extended, improved, or changed, after June 30, 1914, it is essential that certain records shall be prepared and kept by the carriers in their offices, and that certain reports shall be filed with the Interstate Commerce Commission. It is the intent of these regulations to prescribe a uniform method of recording and reporting the investment in extensions, improvements, or other changes, including retirements of physical property.

2. Records to be kept by common carriers, authorities.—Each extension and improvement or other change in the property of a common carrier shall be covered by an authority setting forth clearly and explicitly the general character and location, quantities, and amounts involved in the extension and improvement or other changes. These authorities shall be issued by executive or other responsible officers of carriers in numerical order and separately for owners and states, territories, and the District of Columbia.

3. Detailed records of cost.—The records of common carriers, covering investment in extensions, improvements, or other changes, including retirements, in the physical property shall be kept by jobs, and separately by owners and states, territories, and the District of Columbia in such complete detail as to units and quantities of the material and labor entering therein so as to show a unit of analysis of their cost.

4. Reports of completed work.—Reports of authorized jobs which have been completed shall be made within six months after the completion thereof upon special forms which will be later prescribed by the commission. Such reports shall be summarized, showing distribution by primary accounts, in accordance with the commission's classifications. Reports and summaries shall be made by jobs, and separately by owners and states, territories, and the District of Columbia. The completion reports for such jobs as extend over two or more fiscal years shall be made in full detail for the entire period covered by the work, and the amounts expended in each fiscal year shall be stated in summary form.

5. Reports of uncompleted work.—Reports of authorized jobs which have not been completed by June 30 of each year shall be made in summary form only, showing the cost thereof to said June 30, and distributed by accounts, in accordance with the commission's classifications. Separate summaries shall be made by owners, states, territories, and the District of Columbia, and filed with the commission not later than six months after said June 30.

6. Reports of extensions.—Reports of extensions shall be accompanied by such maps, profiles, plans, or diagrams as are required by the commission's specifications applicable to such extensions.

7. Reports of improvements or other changes.—Reports of improvements or other changes, including retirements, shall be accompanied by such maps, profiles, plans, or diagrams as may be necessary to show their general character.

COMMUNICATIONS

Three-Wire System and Electrolysis Mitigation

ELGIN, ILL., Aug. 12, 1914.

To the Editors:

The articles on electrolysis mitigation which have appeared in recent issues of the ELECTRIC RAILWAY JOURNAL have not contained any reference to the three-wire system and its possibilities in the reduction of the cause of electrolysis. The Brisbane Tramways Company, of Brisbane, Queensland, Australia, has had a plan of this kind in operation for some two years, and, under the local conditions, it has given good results and has kept the drop in potential in our rail return to 3½ volts per mile, as required by the regulations. Complaints of electrolysis of water pipes were formerly very frequent but, since the adoption of this system, there have been no such complaints.

In applying the three-wire principle, we do not have one overhead wire of a double track road positive and the other negative. Instead, our system is divided into several sections, in some of which the trolley wire is positive while in others it is negative. The positive and negative sections are separated by pairs of ordinary trolley-wire section insulators placed several feet apart with, therefore, a short insulated section of trolley wire between. This insulated section is sufficiently short to allow a car to secure current from either side by reversing the trolley pole and it is grounded through a set of five series, 110-volt lamps which will light up if one or other of the section insulators breaks down. This plan for breaking the line up into sections is used because it is unlikely that both section insulators will break down at the same time, and the indicating lamps give a positive notification of trouble.

The positive and negative sections are arranged so that, as nearly as possible, the two sides will carry equal loads. The switchboard is so constructed that sections can be fed either from the positive or the negative busbars by means of interlocked switches. At times of light load the three-wire principle is not used.

A successful method of applying the negative booster principle to the return feeders when the drop in the rail return is excessive has been used with good results in Brisbane. When a number of generators are operating in parallel they are forced to produce the same voltage and the equalizer connection maintains the proper subdivision of load among them. With our system of negative boosting the negative terminal of one generator is disconnected from the negative busbar and is connected directly to certain outgoing return feeders. When carrying its proportion of the total load it will automatically run at 25 to 50 volts higher than the other generators, depending upon the drop in the return feeders and will automatically regulate the voltage at the points of connection to the track with the load drawn. As many points can be connected to this high-voltage generator as its capacity will allow. On the other hand, if the load demand at the negative feeding point is not sufficient to take up the full-load output of the generator the latter can be connected in parallel with the other generators through an equalizing connection having considerable resistance, the value of the resistance being determined by the proportion of load which is to be diverted from the high voltage feeders. I believe that this plan is original with our company.

Positive and negative feeders are carried on the same poles and there has been no trouble in providing the necessary insulation. For convenience of the linemen the negative feeder is painted red. The linemen do not experience any difficulty in handling the feeders, as it is impossible for them to receive more than 550 volts except by touching positive and negative feeders at the same time. We use standard 550-volt generators in the power plant, and they are connected by pairs in series, with the neutral connection going to the rails. We have about 35 miles street length, most of which is double track, and we operate from 100 to 140 cars.

While I realize that the three-wire system has been proposed in the past and that it has been found undesirable under most conditions, I have no doubt that there are places where the principle can be utilized along lines somewhat similar to those here described. The use of parallel positive and negative trolley wires is not desirable, but the division into alternate positive and negative sections has been found, by us at least, to be entirely practicable.

J. S. BADGER,
Manager Brisbane Tramways Company.

Kansas City Franchise

NEW YORK, Aug. 15, 1914.

To the Editors:

In Mr. Kealy's reply to my communication published in your issue of July 18 relating to the new Kansas City street railway franchise, he states that I was "engaged to come to Kansas City during the campaign preceding the election by the local newspapers opposing the franchise." He refers to the Kansas City *Star*. This statement is unimportant, though untrue.

Referring to the forfeiture clause Mr. Kealy says that it was taken from the terminal franchise, and that in my book on "Municipal Franchises" I referred to the terminal franchise as a "most comprehensive and carefully drawn document." The provisions that make this recent forfeiture clause a joke are not in the terminal franchise at all. Moreover, Mr. Kealy's quotation from my book is a misquotation. Instead of using the language he attributes to me, I referred to the terminal franchise as "one of the most comprehensive and elaborate terminal franchises on record in this country." The ridiculous thing about this new forfeiture clause is not its assurance that the company shall have a fair deal when it unwittingly violates some requirement of the ordinance, but its assurance that after the company has wilfully violated the ordinance and has persistently and wantonly refused to make good its delinquency, even after a decree of court, the ensuing forfeiture shall merely put the property into the hands of city trustees, who will have to carry the entire burden of operation with the obligation still to pay the company, in addition to the full return on the full capital value, three-quarters of the company's share in the surplus profits, although the only reason for giving the company any share in surplus profits at any time is to enlist its zeal in efficiently carrying out the purposes of the franchise.

Mr. Kealy refers to my statement in regard to the provision for personal injury claims as "a very curious error, to say the least." I was fully aware of the fact that the provision making personal injury claims a special operating expense subordinate to return upon capital was devised for the alleged purpose of taking care of old tort claims antedating the receivership, but as I read the ordinance it seems clear that all future personal injury claims are included under this provision. In quoting the clause Mr. Kealy conveniently omits the comma which appears in the original after the word "property" and also cuts his quotation short before he gets to the end of the sentence. What the ordinance says is this:

"3. All liabilities for personal injuries and damages to property, including claims due the city up to the time of the adoption of this contract, whether same accrued before, during or after the receivership, shall be paid as a special operating expense, subordinate only to the payments provided for in paragraphs 1 and 2 of this section, and prior to any participation by the city or company in net income."

If this language means what Mr. Kealy says it does, we shall have to exercise unusual caution in the interpretation of this ordinance, following the old adage: "Take a Dutchman as he means, not as he says."

Mr. Kealy argues at some length that there is no chance for the inflation of capital, but he misses entirely the point of my criticism. I will try to make it clear. The ordinance provides that in replacing portions of the property as they are worn out, the additional cost of the new parts over and above the depreciated value of the old parts as set down in the Inventory-Appraisal, shall be added to capital account. Assuming that the entire physical property goes into the Inventory-Appraisal at an average of 79 per cent of cost new, is it not perfectly clear that when this property has been gradually replaced, although the property as a whole will not be increased in value, still the recognized capital value or purchase price will have been increased to the extent of this 21 per cent? The amortization of intangibles provided for in the ordinance extends only to the intangibles already in the valuation, not to those that are to be put in by the renewal process.

In a recent address before the Commonwealth Club of California, Mr. Arnold referred at some length to the intangibles in the capital value recognized under the Chicago ordinances. According to his estimate, the capitalization at the end of the twenty-year franchise period in 1927 will be about $204,000,000, while the real value of the property will be only $140,000,000 or $150,000,000. He explained that $11,000,000 of junk value was included in the original appraisal as the price of peace, and that in the subsequent rehabilitation of the system the intangible value was so increased as to make the purchase price to-day about one-third higher than the real value of the property. "The mistake we made when we passed that franchise was in not providing some sort of an amortization fund for the purpose of gradually retiring that intangible value," says Mr. Arnold.

The amortization provision of the Kansas City franchise takes care only of the original intangible value in the $30,000,000 valuation, which is figured at $7,500,000. The 21 per cent inflation of capital that I am talking about is the additional intangible value which will be put into the capital by the process I have described, much as it is now being done in Chicago.

Mr. Kealy is entirely wrong when he refers to me as alleging that the city was not in a position to effect a favorable settlement. What I really said was very different, namely, that "the city was not in a position where it was necessary to settle on unfavorable terms."

This Kansas City ordinance is so long and so complex that it would require a great deal of valuable space to prove any one of a hundred points as to its meaning which might be asserted in a few lines. But the main point of the Kansas City episode, as I see it, is that it represents a successful attempt by a company, in a resettlement of its own seeking, to induce the city to make good past losses as well as to assume future risks. I agree in principle that the city should assume future risks and thereby change the public utility investment from a speculative to a non-speculative basis, but I cannot agree that this undertaking for the future should be weighted down with the losses of the past.

The overvaluation in the Kansas City case is found in the overvaluation of the existing franchise. The company went into a receivership and predicted all sorts of calamities to itself and to the city if it were not relieved of the existing franchise, and yet this very franchise was appraised by various engineers as being worth from $10,000,000 to $13,000,000, and the company actually got an allowance of $7,500,000 for it in addition to the boost of the guaranteed return from 5 per cent to 6 per cent. It seems curious that the payment of tort claims accruing under a franchise with a future net earning power, over and above a fair return upon the value of the physical property, of $13,000,000, should be treated as alms.

I may be a "soldier of fortune," as Mr. Kealy dubs me, but I am quite scrupulous not to allow myself to be misquoted with impunity in support of a big franchise deal which I do not approve.

DELOS F. WILCOX.

Technical Schools and Electric Railways

PUBLIC SERVICE RAILWAY COMPANY,
NEWARK, N. J., Aug. 17, 1914.

To the Editors:

It seems to me that the general criticism of the inadequacy of the technical schools to meet present-day conditions may be largely justified. Our technical schools have not advanced at the same rate as the special industry. The personnel of the college faculty could do a great deal to keep abreast of the industry by more closely identifying itself with practical work and the deliberations of the various national engineering organizations.

College professors should make a particular effort to engage in actual or consulting engineering work outside of their regular duties. Faculties should encourage outside employment, and members whose services were so sought should be recognized.

Again, take the question of membership in the engineering societies. Speaking of the American Electric Railway Association as one of which I have some personal knowledge, this association represents approximately 80 per cent of the electric railway business in the United States and about $2,500,000,000 of capital. The "Engineering Manual," issued last year for the first time by the allied engineering association, is an example of the great work that is being accomplished. As one indication of the value of this work it may be pointed out that the 7-in. standard rail that was decided upon by last year's convention at Atlantic City has already been adopted by four representative electric railway properties in the United States and Canada.

In looking over the membership list I find fewer than twenty representatives of college faculties. Certainly there are a number of leading colleges that purport to teach something about electric railroading with its various ramifications. How colleges can expect to keep in pace with modern practice without being firmly entrenched with technical organizations that are helping to mold the destiny of the industry I leave for others to answer. Many successful engineers who are locally spending all of their time in electric railroading believe it essential to take active part in the deliberations of the association in order to keep in touch with the best modern practice. The graduate, sooner or later, must compete with these men. Is the graduate prepared if his tutor has not at least laid a foundation for him? Will the college receive words of praise for not turning out such men as the industry requires?

I, for one, am of the firm opinion that colleges, at least as far as the technical association is concerned should encourage the members of the faculties to get outside the college halls. Professors who broaden them selves in this manner should be encouraged and substantially rewarded. Then there would be some competitive instruction introduced in the college, and efficiency will never become dormant where competition exists. The final results would be better for the teacher and better for the graduate and bring greater popularity to the technical schools.

MARTIN SCHREIBER, Engineer Maintenance of Way.

WORCESTER POLYTECHNIC INSTITUTE
WORCESTER, MASS., Aug. 20, 1914.

To the Editors:

I read with interest in a recent issue your editorial under the heading "The Convention and Technical Education." There can certainly be no better way for the college professor to keep in touch with the rapid development in the electric railway field, with the expenditure of a minimum amount of time, than regularly to attend the conventions of the American Electric Railway Association, and this is especially true in the case of the teacher who does not combine his educational work with professional connections which regularly keep him in touch with practical work. In my own case, the habit of regular attendance at the railway conventions was formed long before I attempted any teaching, but in connection with my duties at Worcester Polytechnic Institute I have fully realized the benefits obtained from such attendance, both in the way of keeping closely in touch with current practice and in meeting the men who are responsible for its development.

ALBERT S. RICHEY,
Professor of Electric Railway Engineering.

Los Angeles as an Interurban Center

PACIFIC ELECTRIC RAILWAY COMPANY
LOS ANGELES, CAL., Aug. 11, 1914.

To the Editors:

In connection with the discussion in your paper on the subject of which city runs the largest number of interurban cars or trains per day, the question having been brought up by Mr. Ankeny in the issue of the ELECTRIC RAILWAY JOURNAL of July 25, 1914, I inclose statement showing, by divisions, the number of interurban trains and cars operated by this company in and out of the city of Los Angeles:

NUMBER OF INTERURBAN TRAINS AND CARS OPERATED INTO AND OUT OF LOS ANGELES DAILY

	Trains	Cars
Northern Division	807	1,098
Southern Division	424	598
Western Division	395	566
Totals	1,626	2,262

J. MCMILLAN, General Manager.

Electrolysis Studies in Springfield, Mass.

For the past few months the United States Bureau of Standards has been conducting tests to determine the present condition of the underground pipes and cable sheaths and of the return system of the local electric railway. A preliminary report was recently made to the Public Service Associates, an organization of representatives of public utility company and city officials, at the instigation of which the study has been made. A more formal report giving experimental data and definite recommendations will follow soon. In the final report will be discussed also the question of the cost of delivering power to the cars under the present distribution system, the effect upon such costs of making certain changes in the distribution system and the advantages to the railway company in making the proposed changes.

The Bureau of Standards believes that when the full details of the proposed plan are examined it will be found to the advantage of the railway company, as well as to the owners of underground utilities, to carry out the changes which will be recommended. While the Bureau found that some deterioration of underground pipe is going on the danger from electrolysis of such structures in Springfield cannot be considered as acute or alarming. At the present time there seems to be too much negative copper in certain districts and a better distribution of the return current could probably be secured by a rearrangement of the negative copper. In these districts it is the opinion of the officials of the Bureau that satisfactory electrolysis conditions could undoubtedly be secured with considerably less total copper than is now already installed and at the same time the energy losses in transmission could be very greatly reduced.

Dr. E. B. Rosa, acting director of the Bureau of Standards, expressed his appreciation of the courtesies extended by all of the local interests and of the hearty co-operation received from all of the utility companies participating in the investigation.

ASSOCIATION NEWS

MEETING OF THE COMMITTEE ON STANDARDS

At the meeting of the committee on standards which was held in New York on Aug. 6 and 7, and which was reported briefly in a recent issue, action was taken upon the recommendations of four of the standing committees of the American Electric Railway Engineering Association. The first of these submitted for the consideration of the committee by Chairman H. H. Adams were contained in the report of the committee on power distribution. In this report a specification for rubber-insulated wire and cable for power distribution purposes was recommended for adoption as a standard, Chairman G. W. Palmer, of the committee on power distribution, presenting a brief outline of the work of the committee on this subject for the past year and stating that the points of difference between the proposed specification and that of the underwriters' association had been overcome. During the discussion which followed it was brought out that the Association of Railway Electrical Engineers had a substantially similar specification except that only one grade of cable was covered, the less expensive grade for which provision had been made in the proposed specification not having been included, and that the same thing applied to the practice of the New York Central Railroad. It was finally decided to adopt the recommendation of the committee as the standard, including the two grades of insulation as proposed.

The specification for round and grooved high-conductivity trolley wire was then taken under consideration, the committee on power distribution recommending that the present specification covering No. 00 round, hard-drawn copper trolley wire be expanded to cover No. 000 and No. 0000 round and grooved trolley wire. After the reading of the proposed specification it was moved for adoption as a standard and the motion was carried.

A number of other recommendations of the committee on power distribution were then approved, including a request for further time to investigate the subject of reinforced-concrete poles and to prepare a specification for sundry line materials. The suggestion to discontinue investigation of the influence of large short-circuit currents on multiphase cables and the dynamic force exerted between conductors during the time that short-circuits existed was approved owing to the fact that a representative of one of the member companies was giving the subject thorough study, with the expectation of presenting his conclusions in the form of a report. A minor correction was made in the specifications for high-voltage, three-conductor, paper-insulated, lead-covered cable as recommended by the power distribution committee.

REVISED SPECIFICATION FOR GALVANIZING

The revision of the present standard specification for galvanizing iron and steel so that it would include sherardized materials was then approved, as was a recommendation that the standard copper wire tables be revised by correcting the values of the resistance to provide for the physical changes in the wire due to the assumed temperature changes. Minor changes were approved in the standard stranding cable and in the wire and cable terminology. Changes were also approved in the present recommended specification for 600-volt d.c. overhead trolley construction, these including the installation of span wire on tangents, the suggested sags for trolley wire, formulas for dressing trolley wire at curves, and the location of lightning arresters; but a suggested change regarding the method of grounding lightning arresters was referred back to the committee on power distribution for further consideration.

The clearances for overhead structures which were submitted at the last convention by the committee on heavy electric traction were presented to the committee on standards for adoption as a recommendation of the association, it being stated that the American Railway Engineering Association had already adopted similar clearances as standard. The recommendation of the committee was adopted.

The committee on way matters then submitted drawings covering four types of foundation for use in paved streets for adoption as recommended designs, each of these designs being intended for use only after consideration of the sub-soils and other conditions obtaining. These drawings were discussed at length and referred back to the committee on way matters for further consideration.

The session on Friday was devoted largely to a consideration of the recommendations of the committee on equipment, presented by F. W. Phillips, chairman.

NEW DESIGN OF JOURNAL BRASS

Among the new subjects brought to the attention of the committee on equipment during the past year was that of the necessity for a new design of journal brass for high-speed heavy electric traction. The committee on equipment recommended that the matter of developing a new standard journal brass to replace the present M.C.B. standard in high-speed service should be referred to the ensuing committee on equipment for consideration jointly with the Master Car Builders' Association, and this recommendation was concurred in by the committee on standards.

In the matter of wires and cables for car equipment, the recommendation of the committee on car equipment to postpone consideration was approved, but the suggestion was made that the general subject should be referred to the ensuing committee with special reference to fire protection, and that a specification for car wiring should be prepared, giving consideration to the specifications on wires and cables for power distribution which had already been adopted.

Several minor changes in the present specifications for solid wrought carbon steel wheels for electric railway service which were recommended by the committee on car equipment were approved by the committee on standards, placing the specifications in form for adoption as a standard of the association. Proposed new specifications for air-brake hose were then discussed at length. The recommendation that the study of the subject of lightning protection should be continued was also approved by the committee on standards.

Mr. Schreiber, as a member of the committee on the "Engineering Manual," then made a report on this subject, speaking about the probable necessity for culling out miscellaneous practices in the near future to provide room for the large amount of material that would soon have to be included among the standards and recommendations of the association. After a discussion of this matter the meeting adjourned.

INDIVIDUAL MEMBERSHIP

Secretary E. B. Burritt wishes to call attention to the following fundamental matter regarding individual membership in the American Association. To be eligible for individual membership an applicant must be an employee of an operating company which is a member of the American Association or an employee of a member of the Manufacturerers' Association. This announcement is made to avoid possible disappointment at Atlantic City. The rule does not apply, of course, to individuals, like college teachers, outside the immediate railway business whose employers are not eligible to membership in either association.

MANUFACTURERS' ASSOCIATION

Mr. McConnaughy's latest circular emphasizes the necessity for prompt shipment of goods in order to allow for all freight delays, possible bad weather conditions in Atlantic City previous to the convention and the further fact that all goods must be delivered on the Pier before Saturday, Oct. 10, to be set up, as no work will be allowed on Monday. All night and Sunday work, also Saturday afternoon, should be avoided, as this will cost double time. Manufacturers should arrange to have their men on the ground a day or two earlier so that all electrical and other mechanical work can be completed without overcharge and everyone may be given a chance to rest up Sunday. With this circular letter are enclosed order blanks for drinking water.

The Pier has been put in unusually fine shape for the convention, which is now only seven weeks off.

New members secured by the Association during the past week are S. Abrahams & Company, Philadelphia, Pa., and the Detroit Graphite Company, Detroit, Mich.

Some Safety Rules in St. Louis

The Union Electric Light & Power Company, of St. Louis, has promulgated additional safety rules, some of which follow:

Railings are to be erected where, on the company's properties, preventive measures are necessary to keep pedestrians from stepping on railroad tracks.

Picket doors are to be installed at stations so that solid wood doors may be left open in warm weather without possible danger to public.

Switchboard guards are to be erected wherever such construction is of advantage from the standpoint of safety.

Walkways on crane and other apparatus are to be equipped with railings wherever needed.

Pole ladders are to be equipped with chain at the top so that ladder rests firmly against pole to lessen danger from the ladder turning when it is subjected to weight.

Equipment and Its Maintenance

Short Descriptions of Labor, Mechanical and Electrical
Practices in Every Department of Electric Railroading

(Contributions from the Men in the Field Are Solicited and Will be Paid for at Special Rates.)

The Return Circuit—General Considerations

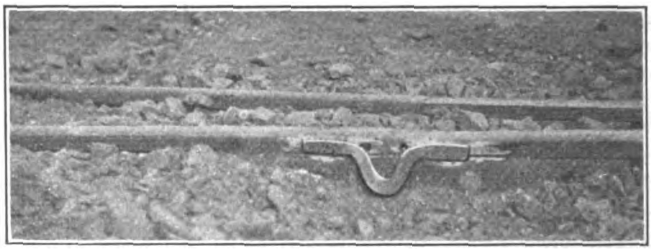
BY HOWARD H. GEORGE, ASSISTANT ENGINEER MAINTENANCE OF WAY, PUBLIC SERVICE RAILWAY, NEWARK, N. J.

The fundamental principle in bonding is to secure a rail which is electrically a continuous conductor from the power house to the end of the line. The great importance of properly designing the return circuit is now arousing more interest every day among operators of street railway properties, and is being generally recognized, not only from the standpoint of saving in energy consumption, but also from that of minimizing electrolytic action.

REQUIREMENTS OF A GOOD BOND

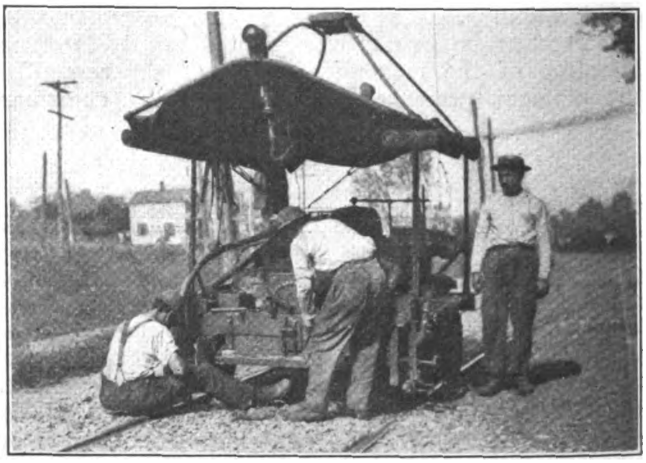
Poor bonding has been generally emphasized as the most important defect in the return circuit. Of course, other elements such as an increase in the temperature, higher percentage of carbon or manganese in the steel, etc., tend to increase the resistance of this circuit, but the principal resistance factor is offered by the joints. A satisfactory bond must fulfil at least three conditions, namely, mechanical strength, electrical contact for conductivity, protection from injury or theft.

Here it might be well to show why mechanical bonds installed in connection with bolted joints do not retain their efficiency as a conductor indefinitely. It may seem an easy matter to secure a perfect return circuit, but practically the reverse is true. The trouble is not so much in bonding a joint properly in the beginning as it is to maintain the same for any great length of time. The only way to maintain a mechanical joint properly is to go over it at frequent intervals, tighten up the bolts and keep the ties tamped up well under the joints. It will at once be realized that this would not be practicable in the case of track laid in city streets and inclosed in an expensive type of paving; and as a result, any mechanical bond is bound to suffer more or less. The cost of properly maintaining such a joint, and consequently the bond, under these conditions would be prohibitive, and would very soon amount to more than the saving in power which would result from the better bonding across the joint. The Public Service Railway has very largely solved the problem of maintaining the rail bond by making extensive use of an electrically-brazed bond. The apparatus used for the installation of this bond as illustrated on this page is that of the Electric Railway Improvement Company, Cleveland, Ohio. The three or four men required for its operation can install from eight to fifteen bonds per hour, depending upon traffic conditions, power, etc., the entire expense including cost of bond being only about 50 cents per bond. Of course, where plates and paving must be removed and replaced, the total cost per joint will be much more than this figure. The second illustration shows a portable grinder in use for polishing the surface of rail to which the bond is to be applied, while a third view shows a complete bond installation. This grinder is of the Electric Railway Improvement Company's type, but our company has also purchased a somewhat similar portable grinder from the Pneumatic Tool Company.



RETURN CIRCUITS—BRAZED BOND AS INSTALLED ON PUBLIC SERVICE RAILWAY

RETURN CIRCUITS—GRINDER FOR BRAZED BONDS



RETURN CIRCUITS—CAR FOR APPLYING BRAZED BONDS

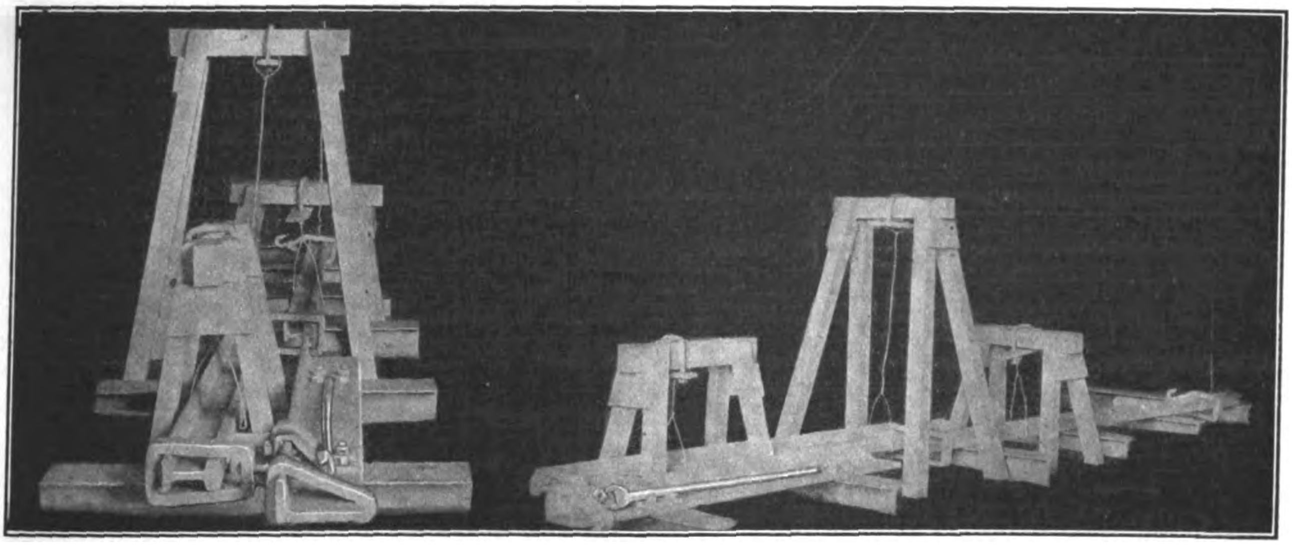
THEORY OF MECHANICAL JOINT FAILURE

In view of the statement that it is not practicable properly to maintain a mechanical joint indefinitely in paved streets, an explanation of the generally accepted theory of the plate joint and why it cannot be kept tight indefinitely without constant attention, with the possible exception of track carrying the lightest kind of traffic, may prove interesting. Outlined as briefly as possible, the solidity and permanence of a joint depend upon the thorough, continuous and tight contact of the two plates against the rail ends. In any form of rolled steel the two sections are never uniform, and consequently, in the case of rails, the two abutting ends are not of the same section, the variations sometimes being as much as 1/16 in. This is also true of the plates themselves. Yet even if it is assumed that sections of both the plates and rails are exactly the same, rolled steel surfaces are not perfectly smooth but consist of very small elevations and depressions; consequently instead of having a continuous contact between the rails and plates, only an intermittent or point contact is obtained. Under car loading only, the plates would have to resist the vertical and lateral movements, but in addition to these movements there is also the bodily or longitudinal movement of the rails themselves, due largely to temperature changes. There is also a wave motion in the rail itself as the wheel loads pass over it. These movements act on the small irregular surfaces like a file. While such movements are only ¼-in. to ⅜-in. (even in severe changes of temperature), yet the point contacts are so small compared with the extent of the rail movement that the action is the same as that of a file. Hence no matter how tightly the plates may have been adjusted originally, they quickly work loose and the ends of the rails soon begin to hammer and pound under the wheel loads. In addition to these causes, the nuts are continually being jarred loose by vibration. The nuts also work loose due to stretching of the bolts themselves, since with the nut-lock now in general use, a very slight loosening or stretching of the bolt immediately destroys its usefulness.

The only permanent solution of the joint and bond problem lies in the adoption of some form of welded joint to make a practically continuous rail. The Public Service Railway has adopted the Lorain electric joint as standard on all new construction and reconstruction work. Where five years or more additional life can be obtained from the old rail by welding this is done, and much rail has thus been saved from the scrap heap. During recent years this welding has been applied even to several miles of T-rail in both open and closed track, expansion joints being placed approximately every 1000 ft. with very gratifying results on joint maintenance and power return. Up to the end of 1913 approximately 60,000 electrically welded joints had been installed. The fact that such large railway companies as those in St. Paul and Minneapolis, Cleveland, Chicago, Philadelphia, Brooklyn, Pittsburgh and Buffalo, as well as our own, have reduced the use of bolted joints in city streets to a practicable minimum is the strongest evidence of the modern tendency to get farther away from the joint maintenance problem by the adoption of some type of welded joint or a combination of weld and riveted joint. Were it not for the high cost of welding a comparatively few joints at any one isolated location, many other smaller companies now using plate joints would at once abandon them for some form of welded joint.

Determining the Proper Length of Wrench for Track Bolts

BY P. NEY WILSON, ROADMASTER CONNECTICUT COMPANY



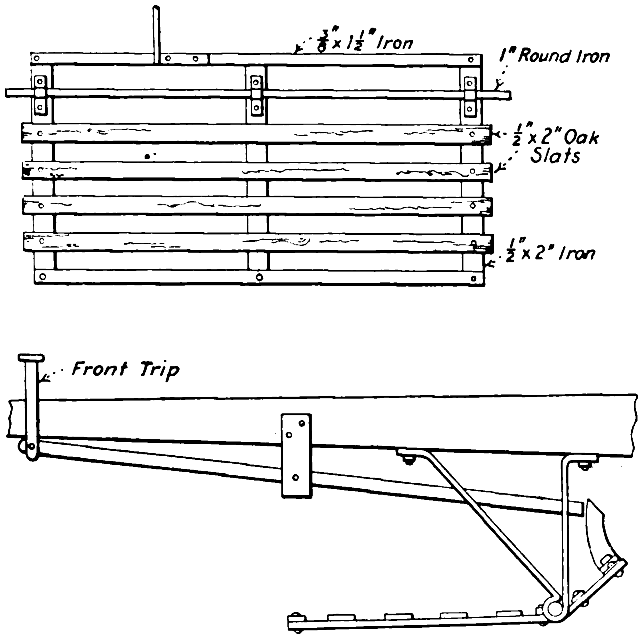
VIEWS OF CONNECTICUT COMPANY'S MACHINE FOR DETERMINING PROPER LENGTH OF WRENCH FOR SETTING UP TRACK BOLTS—WRENCH AND NUT OF BOLT UNDER TEST ARE IN FOREGROUND

In investigating the proper length of wrench to use in setting up track bolts the maintenance of way department of the Connecticut Company has devised a novel apparatus for this purpose. In taking the problem to the department a wide difference of opinion was shown. The experience of other electric railways as well as manufacturing concerns was then solicited without satisfactory results. No conclusion based upon actual existing conditions seemed to be available. We felt that some of the factors entering into the problem were assumed, and the device as shown herewith was the result of much study on the subject. Tests on this machine eliminate friction of the nut when it turns on a Harvey grip thread as well as when the nut sets against the joint plate. The actual stress on the track bolt as manifested by the lateral movement of the beams, is registered on a spring scale which is attached to a hook welded to a shackle iron on the second beam. The fulcrum points are knife-blade edges made from a short section of 7-in. T-rail, the head being cut off and the web sharpened to an edge. They are bolted securely to the base of 7-in. T-rails placed at right angles under the beams and imbedded in concrete. Both beams are made of low T-rails, ratio 1 to 10, slotted at fulcrum points and at the shackles. Accurate results can be obtained by having a track man set up the bolts as he would in the track, using wrenches of different lengths, and measuring the bolts before and after to determine whether or not this elastic limit has been exceeded. The scale in each test will show the stress on the bolts. A spring scale may also be attached to the upper end of the track wrench, showing the pounds pull on the wrench. This machine was made at a nominal cost and with it very interesting results can be obtained without resorting to any assumed factors. With reference to the wires shown in the views the following may be added: The wires attached to the two wooden horses, including the vertical wire at the end of the second beam, suspend the beams in such a way that they are free to move at the slightest pressure.

A Good Home-Made Fender

BY J. N. GRAHAM, SHOP FOREMAN ROCKFORD & INTERURBAN RAILWAY, ROCKFORD, ILL.

The accompanying diagram shows a good home-made fender which has been in use for the past few years on the Rockford & Interurban Railway's city cars. The frame of the fender is made of three pieces of ½-in. x 2-in. iron 30 in. long, bent to an angle of 45 deg. 6 in. from one end. The rest of the frame comprises two pieces of ⅜-in. x ½-in. iron 6 ft. long. The five pieces are put together with ⅜-in. rivets. The fender is hung on a piece of 1-in. round iron 6 ft. 6 in. long by means of three clips which are riveted in the angle of the 1½-in. x 2-in. frame at the sides and center. This 1-in. round bar is held up by two brackets made from ⅜-in. x 1½-in. iron which are bolted to the bottoms of the vestibule knees. The frame of the fender is covered with ½-in. x 2-in. oak strips 6 ft. 4 in. long which are bolted to the sides and center pieces with ¼-in. x 1¼-in. stove bolts. The trip is made of a piece of ½-in. x 1-in. iron bent to a right angle on the end that supports the fender, a piece of ⅜-in. x 1½-in. iron bent as shown in the sketch being riveted to the top piece of the fender frame which rests against the trip. A very slight pressure on the trip with the foot will drop the fender. A damaged fender is very easily repaired, as the irons are seldom broken.



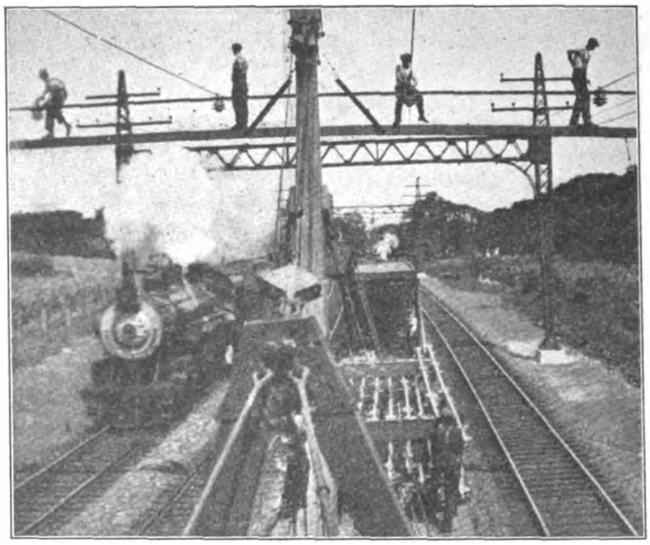
FENDER MADE AT THE SHOPS OF THE ROCKFORD & INTERURBAN RAILWAY

A trial trip was recently made on the newly electrified London & South Western Railway in London, England. The trip was made between Wimbledon and East Putney with one of the new electric trains to be used on this railway. The new coaches will each carry about 200 passengers.

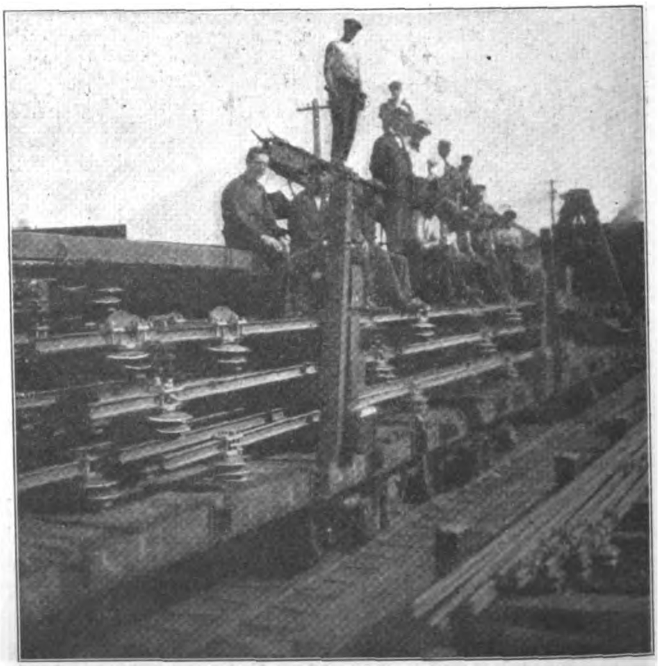
New Haven Railroad Construction Notes—Putting Up I-Beams

BY A FORMER INSPECTOR

In putting up the intermediate transverse I-beams for the electrification of the New Haven Railroad we used a train which was composed of an engine, derrick, tool car and coach, and two to four flat cars to carry the I-beams themselves. These I-beams and their insulators, etc., were assembled in the storehouse preliminary to their erection, those for four-track construction having four main-line insulators spaced to correspond with the track spacing. As shown in a view of one of the flat cars, the I-beams were placed on racks which could be added or taken off as fast as the beams were loaded or unloaded. These I-beams were erected with the help of a cradle about 40 ft. long and supplied with racks to hold two members. The load line of the derrick was attached to a steel strap in the middle of this cradle. After the cradle was loaded, the derrick lifted



INSTALLING I-BEAMS, SHOWING CRADLE AND DERRICK; ALSO PASSING TRAIN UNDER THE CRADLE WHILE MEN ARE WORKING



COMPLETE LOAD OF I-BEAMS WITH INSULATORS ATTACHED READY FOR INSTALLATION the cradle, the I-beams and the four erectors up to the ⅞-in. steel messenger. The men put the clamps in the ⅞-in. messenger and then the end men dropped a plumb line which was sighted to a mark previously made on the outside rails at the location intended for the I-beam. After the first I-beam had been attached to the ⅞-in. messenger the cradle was lowered so that the cradle and racks were clear of the beam. Then the train moved ahead to the next location where a second I-beam was installed in the same way as the first one. As the upper view shows, this method of installation blocked only one track.

Results of a Brush Test for Interpole Motors at Montreal

BY KEITH MACLEOD, MONTREAL TRAMWAYS

The brush test hereinafter described was made on two of the newer types of motors recently purchased by the Montreal Tramways. These motors are of the fully ventilated, interpole type with slotted commutators, all features which did not belong to the motors formerly in use on this road. As the commutation was so different, it was thought advisable to make tests to find a suitable brush for these motors when operated under Montreal conditions.

The test was begun early in the winter of 1913 and continued till the middle of June, 1914, two sets of measurements being taken to determine whether the rate of wear increased in proportion to service or not. As all the motors were new, with uniform spring tension and commutators, it was expected that reliable results could be obtained in a shorter time than is usual with old motors. On the first type of motor, "A," we tried five types of brushes (which we can call 1, 2, 3, 4 and 5), but two of these (1 and 2) proved so unsatisfactory that they were removed after a few weeks. On the other motor, "B," brushes 2, 3, 4 and 5 were used throughout the entire testing period.

To obtain the same conditions for each type of brush they were distributed among the motors so that two or more types appeared on each car. Cars were inspected at the regular intervals and no special attention was given to the brushes except to see that none of those on test had been removed. No attempt was made to discover the effect of variation in spring tension on the wear. With motor "A" the minimum allowable tension was 8 lb. per spring, or 10.5 lb. per sq. in., the high pressure being necessitated by the tendency of this motor to flash over when running at high speed over rough track. The 5 lb. per spring (5.3 lb. per sq. in.) used in motor "B" is the manufacturer's standard and was adhered to as closely as possible.

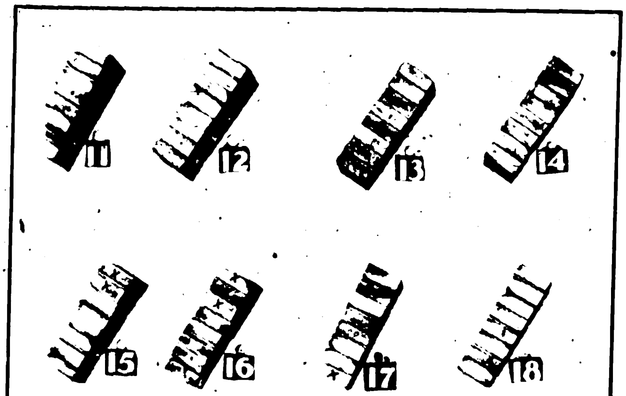
SUMMARY OF MONTREAL BRUSH TEST ON NEW INTERPOLE MOTORS, 1913-1914

					First Period		Second Period		Entire Test				
Type Brush	Type Motor	Number Brushes Tested	Number Brushes Broken or Worn Out	Number Brushes Chipped	Average Mileage	Average Wear per 1000 Miles, In.	Average Mileage	Average Wear per 1000 Miles In.	Average Mileage	Average Wear per 1000 Miles, In.	Estimated Life of Brush, Miles	Cost per Motor per 1000 Miles, Cents	Remarks
1	A	32											Bad chipping and side wear test discontinued.
2	A	8	8										Test discontinued.
2	B	32	3	30	13,170	0.0104	7,620	0.0077	20,790	0.0094	120,000	0.38	Brush unsatisfactory, too much chipping.
3	A	48	6	20	*16,510	0.0198	**8,080	0.0210	21,700	0.0194	45,000	1.98	Considerable chipping, brushes otherwise very good.
3	B	16	0	15	11,780	0.0094	7,960	0.0074	19,740	0.0085	132,000	0.75	Some motors had 0.040 in. mica: more brushes chipped in these than in motors with 0.025 in. mica.
4	A	16	0	9	7,530	0.0205	8,250	0.0173	15,780	0.0185	47,000	2.1	Brushes very good.
4	B	16	0	6***	12,250	0.0096	7,480	0.0102	19,730	0.0098	115,000	1.04	Brushes very good.
5	A	16	0	7	14,640	0.0236	7,920	0.0255	22,560	0.0243	36,000	0.96	Brushes very good.
5	B	16	0	2***	14,080	0.0078	7,780	0.0074	21,860	0.0077	146,000	0.24	Brushes very good.

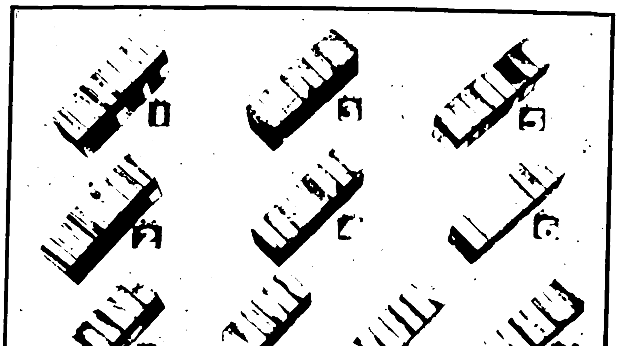
Average cost, all brushes—Motor "A" 1.68 cents per 1000 miles.
Average cost, all brushes—Motor "B" 0.60 cents per 1000 miles.

*48 Brushes.
**32 Brushes.
***Very slightly.

The accompanying table and halftones show the principal results. Brushes marked with black crosses are those replacing brushes which were worn out or broken before the completion of the test. It will be seen that the main trouble encountered was bad chipping at the edges of the brushes. Practically all cars are equipped for single-end operation and there are loops at the ends of most runs, so that the brushes wear all one way and develop very sharp edges. Fortunately the most eco-



BRUSHES OF MOTOR "A"—GROUPS 11 AND 12 (NO. 4); GROUPS 13 AND 14 (NO. 5); GROUPS 15, 16, 17 AND 18 (NO. 3)



BRUSHES OF MOTOR "B"—GROUPS 1 AND 2 (NO. 4); GROUPS 3 AND 4 (NO. 3); GROUPS 5 AND 6 (NO. 5); GROUPS 7, 8, 9 AND 10 (NO. 2) nomical brush (No. 5) was remarkably free from chipping, but it was found that it could be prevented in all types by an occasional beveling of the edges. This trouble is one that has appeared with the introduction of slotted commutators, as formerly we did not have it to any extent.

Another condition that developed was the hammer wear on top of the brush, particularly in motor "A." Appearances indicate that on motors with slightly eccentric commutators or other causes of hammer movement, deep wear and breakage on the tops of brushes would result before they had attained their full life. This applies about equally to each type of brush.

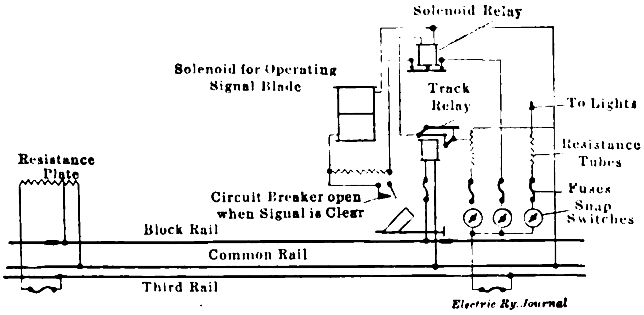
The effect on the commutators was practically the same with all brushes, the wear being entirely negligible as compared with the probable life of the motor. The surfaces were perfect except in two or three motors where the mica had not been thoroughly removed.

The selection of the most suitable brush was made on a basis of cost per 1000 miles. There is no remarkable difference in life of the various brushes as applied to the same type of motor, but a large difference between the two types of motors, evidently due to the different spring tensions, was observed. On this account the decision was largely a question of the relative costs of the three types which give satisfactory service, and as the most satisfactory was also the cheapest, selection was easy.

It was decided some time ago to undercut the mica of all our armatures, and a similar test is now in progress to find the best brush for the non-interpole motors with slotted commutators.

Solenoid Signals of Interborough Rapid Transit Company

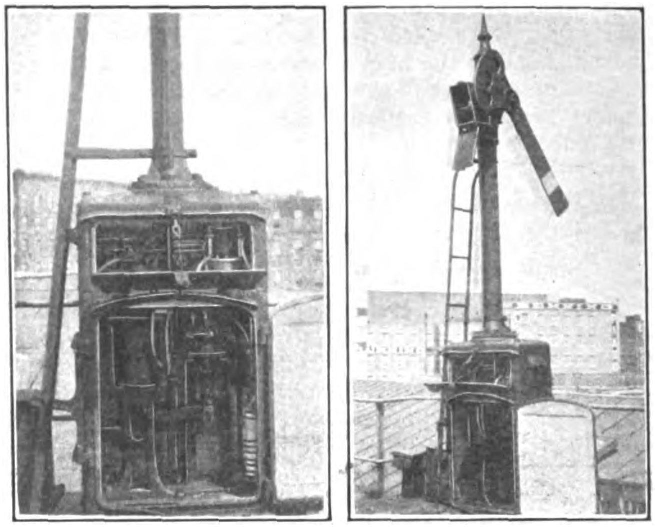
An ingenious modification of the standard semaphore type of signal has been in use for some time on the Manhattan Elevated division of the Interborough Rapid Transit Company in New York City. In this device the operating mechanism for the semaphore blade is replaced by a solenoid which is normally energized from a resistance tap from the third-rail feeder, the signal being held in clear position against the attraction of gravity while power is on. A track circuit is made up by insulating a section of one of the running rails, and this is also supplied with current at reduced voltage from the third-rail, a d.c. track relay completing the circuit at the opposite end of the block from the point of feeding.



Electric Ry. Journal

SOLENOID SIGNALS—DIAGRAM OF CIRCUITS

The track relay, when energized, holds closed another relay which controls the circuit to the solenoid. When the presence of the wheels of a train within the block short-circuits the track relay, the solenoid relay is deenergized and breaks the main solenoid circuit, permitting the counter weight of the semaphore blade to fall and raise the blade to stop position. In this position of the blade a circuit breaker, directly connected to it, is closed, and when the train leaves the block, permitting both relays to pick up, the main solenoid is subjected to full third-rail voltage. As the blade clears, however, the circuit breaker opens and puts the current through a resistance in parallel with it so that, normally, only a small flow of current exists, this being enough to hold the blade clear, although not enough to put it in motion.



SOLENOID SIGNALS—VIEWS SHOWING INTERIOR OF MECHANISM CASE AND CIRCUIT BREAKER ON BLADE

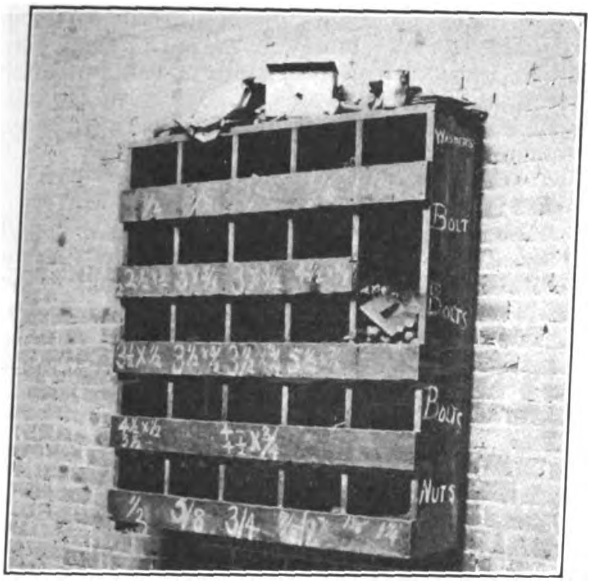
These signals, which are very inexpensive to install and to maintain wherever propulsion current is as plentiful as it is on the Manhattan Elevated Railway, are installed at all bad curves on the line, an accompanying photograph of a typical installation showing the severe conditions. All operations are, of course, for double track, protection being required for following movements only. The signals are home-made in so far as erection and construction of the solenoids go, but standard semaphore blades, masts, casings and relays are used.

SOLENOID SIGNALS—VIEW OF TYPICAL INSTALLATION AT SHARP CURVE ON ELEVATED RAILWAY

Two Handy Boxes for Supplies

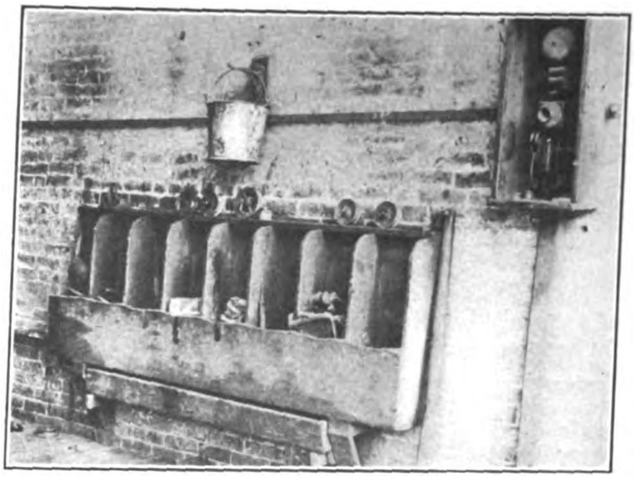
The two accompanying halftones illustrate two convenient receptacles for supplies used by the operating department of the Springfield (Mass.) Street Railway at the Carew Street carhouse.

The first view shows a bolt and nut storage box of twenty-four compartments, located on the wall of the inspection division of the carhouse. The standard bin size is 8 in. x 8 in. x 9 in., the front strips being about 4 in. high, and the box practically 4 ft. square and 9 in. wide over all.



HANDY BOLT AND NUT BOX, SPRINGFIELD, MASS.

The second illustration is a view of a handy box 6 ft. 9 in. long and 3 ft. 8 in. high, divided into eight compartments 9¼ in. wide and 28 in. high, with partitions 6 in. deep, the box being mounted against the wall of the carhouse within a few steps of the street, so that replacements of trolley wheels, controller parts, contactor fingers, terminal blocks and other fittings can be made quickly without withdrawing a car from service. A drawer 4 ft. 8 in. long, 3½ in. deep and 5½ in. wide at the bottom carries the smaller repair parts, the bins holding journal box covers, brasses, light truck parts and trolley wheels. The partitions are ⅞ in. thick, and the planking at the bottom of the bins is 12 in. high, to prevent stock from dropping out on the floor and rolling into the pits. A shelf 2½ in. wide at the top is also found a convenience.



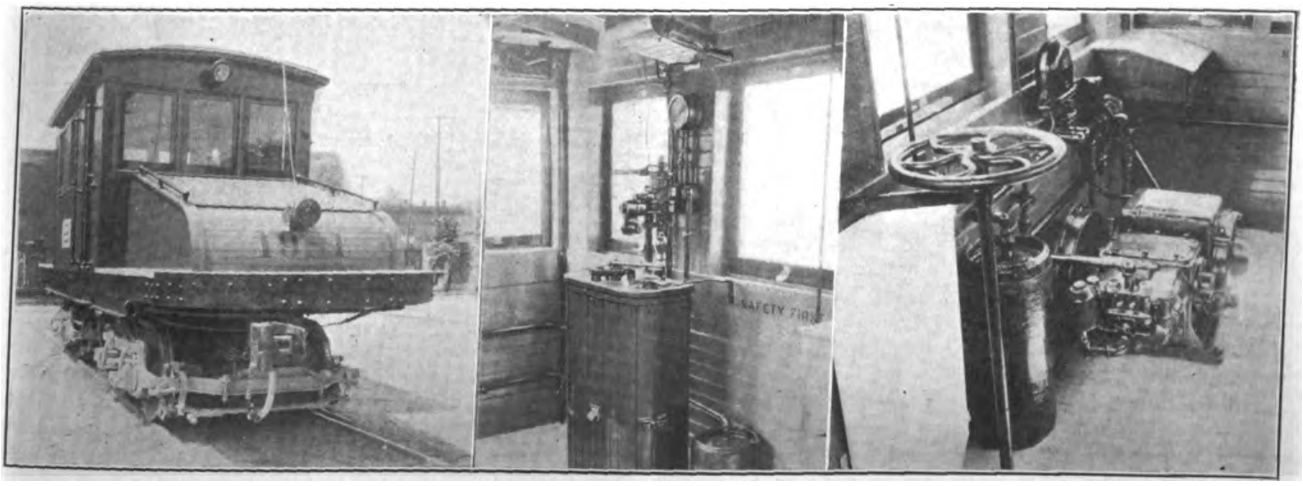
CONVENIENT SUPPLY BOX, SPRINGFIELD, MASS.

Although both of these boxes are of rough construction, their location close to the track has saved a great deal of time in light maintenance work.

Detroit Switching Locomotive

The Detroit United Railway has recently completed the sloping cab type switching locomotive for double-end operation shown in the accompanying illustrations. This locomotive, which is used for handling cars at power houses "A" and "B," is 31 ft. 1½ in. long, 8 ft. 6¾ in. wide over all, 12 ft. long over the body, 6 ft. 7¼ in. clear inside width and 11 ft. 10 in. high from the head of the rails to the top of the trolley board. The locomotive is mounted on two Brill 27-F trucks, spaced 14 ft. centers, with 4-ft. wheelbase and 33-in. diameter cast wheels. The operating equipment comprises four Westinghouse 56 motors geared 14:68, K-14 controller, with resistors under the locomotive, Westinghouse quick-acting automatic air brakes, Peacock hand brakes and Tomlinson M. C. B. drawbars. The weight of the locomotive complete is 42,000 lb.

The underframe has 7-in.—9¾-in. channel outside sills and 7-in. 72-lb. grooved girder rails for center sills. The subsills are also 7-in. 72-lb. grooved girder rails. The sloping ends of the cab are provided with trap doors. The front compartment contains the air tanks, while the rear compartment can be used for tools, etc., in case the locomotive is ever put to any other service.

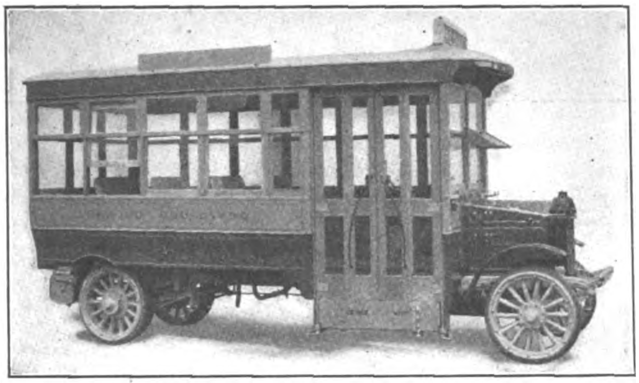


END-VIEW AND TWO INTERIORS OF DETROIT SWITCHING LOCOMOTIVE SHOWING DISPOSITION OF CONTROLLER, AIR-BRAKE, CIRCUIT BREAKER, HAND BRAKE AND COMPRESSOR MECHANISM

Entrance and exit are provided by a solid wooden door on each side, an angle-iron step and grab handles being provided for each door. The illustrations of the interior show how the braking and control equipment is distributed. It may also be added that the slogan "Safety First" is stenciled both inside and outside the locomotive as a constant reminder to the operators and yardmen to exercise caution.

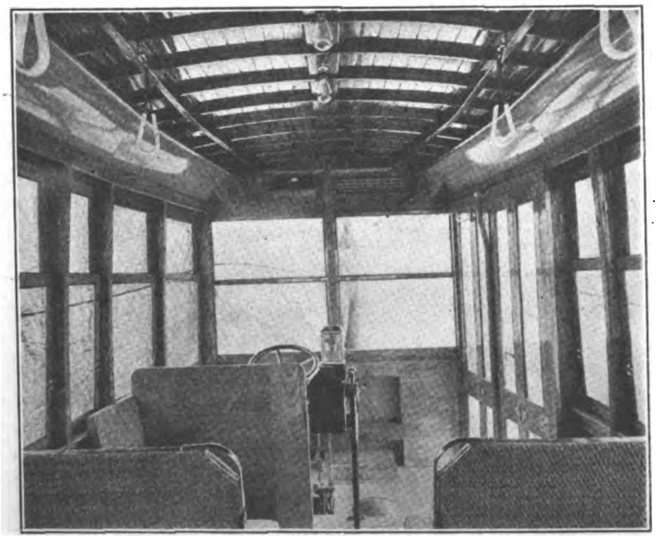
Near-Side Buses in Birmingham

The usefulness of the motor bus for the development of suburban territory is exemplified by the purchase of four motor buses by the Birmingham Realty Company, Birmingham, Ala. These buses were built by The J. G. Brill Company.



VIEW OF NEAR-SIDE BUS WITH FOLDING DOORS CLOSED AND STEP RAISED

The buses are now in service on a regular schedule between the downtown section of Birmingham and a high-class residential realty development known as the "Norwood Property," located 3¼ miles from the center of the city. A condition very favorable for the operation of buses is that the entire route is over asphalted streets. The vehicles have been in service since the third week of July and have proved a popular solution of the problem of carrying people to and from this section.



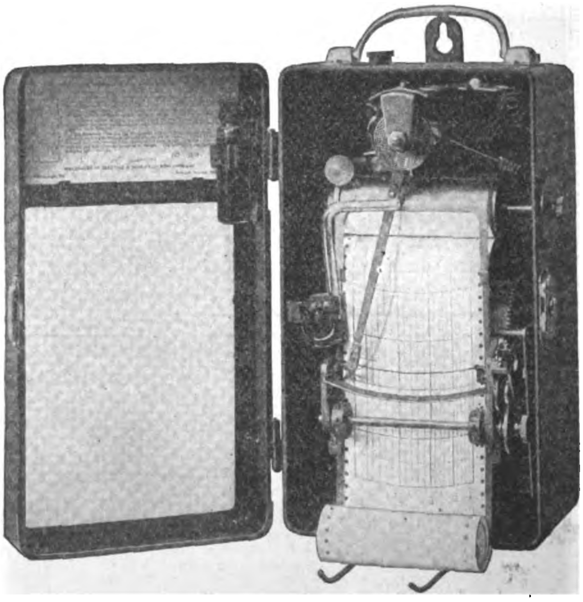
INTERIOR OF BUS AT ENTRANCE

The buses are 15 ft. 6 in. over the body, 6 ft. 11¾ in. over the sills and 7 ft. 4½ in. over all. The body is constructed of wood with plain arch roof and composite underframe. The interior trim is of clear ash with exposed carlines. A two-ton Pierce-Arrow chassis is used. The bus steps are of the folding type, arranged to operate in connection with double-leaf glazed folding doors on the near-side car principle. A vertical stanchion separates colored from white passengers. The height from the roadway to the first step is 14¼ in., from the step to the platform 10 in. and from the platform to the bus floor, 10 in. The conductor collects fares with the aid of a Dayton fare box. The seats are of Brill cane style with pressed steel frames. Perry ventilators are used on all buses. Heaters connected with the exhaust from the engine will maintain satisfactory temperature during the winter months. The lamps are lighted from a storage battery. Standing room conditions have been provided for not only in furnishing seats with corner grab handles, but in supplying Rico sanitary straps. The buses have push buttons as in standard prepayment cars.

Graphic Meters

The graphic meter has a wide field of usefulness, especially for locating leaks and theft of current, determining most economical hours for operating generators of various sizes and checking up the distribution of load between units. The Westinghouse type U graphic meters of the style shown are intended primarily for purposes where graphic meters that are easily operated, light in weight, comparatively low in price and reasonably accurate are required. The continuous records of the type U meters, covering a week's time on a single chart, make it possible for central stations to secure at a reasonable cost a number of records much desired, but not previously obtained because of the expense. The extended uses to which graphic meters of this class have been put have brought out points of improvement that have lately been made in the above-mentioned meter.

The meter consists of a solenoid and core acting directly on an arm that carries the recording pen, and a continuous strip of paper moved uniformly by a high-grade clock mechanism. To overcome the slight friction of the pen on the paper, the solenoid is made very powerful in action. This action is controlled by a heavy spring, which also minimizes inaccuracies due to slight errors in leveling. An oil dash-pot is provided to damp the action of the meter's fluctuating current or voltage. On circuits not subject to excessive fluctuations, the oil can be left out of the dash-pot.

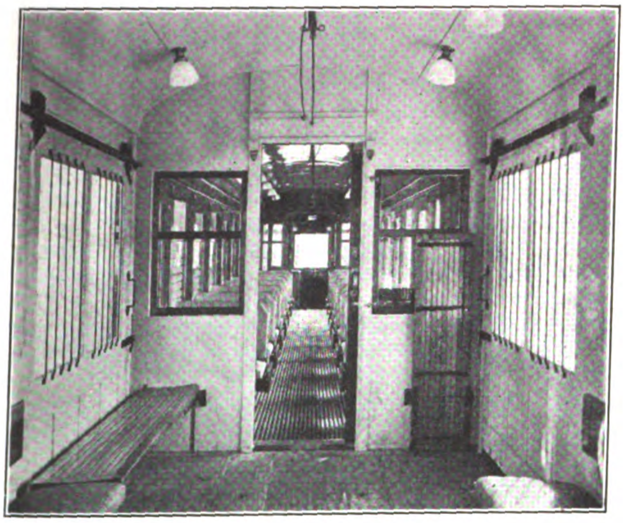


GRAPHIC METER WITH COVER OPEN

A glass ink reservoir, a new feature, which will hold a supply sufficient for three weeks or more of ordinary use, is mounted in such a way that a wick, one end of which is in the reservoir and the other in the V-shaped pen, will feed the ink into the pen as used. The ink is furnished in liquid form and is specially prepared to give good results with the pen and paper supplied. A small clip inside the meter case serves to hold the ink phial, so that the ink is always on hand when wanted.

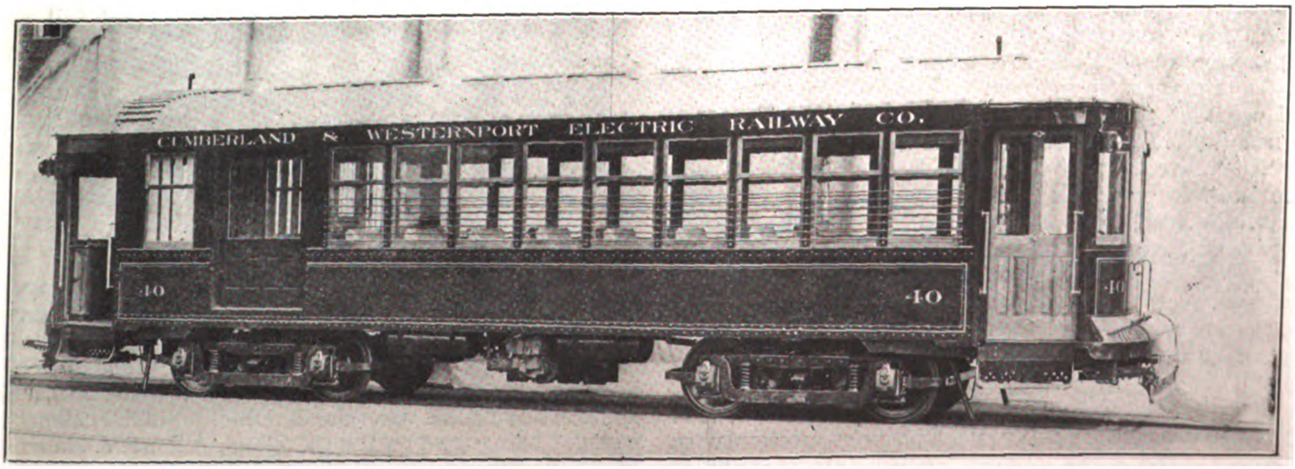
The record paper for these meters is of stock specially selected for satisfactory records and is accurately ruled. The hours are stamped on one margin, and an accurate drive is assured by perforations in the paper in which pins on the driving mechanism engage. The paper is 3¼ in. wide, 2½ in. being occupied by the calibrated part of the scale, which has well spaced legible divisions throughout 2¼ in. in its width.

Combination Cars for Maryland



INTERIOR OF CUMBERLAND CAR AT PARTITION

The Cumberland (Md.) & Westernport Electric Railway has lately received from The J. G. Brill Company two arch-roof cars built for combination passenger and express service. These cars are 43 ft. 3 in. long over the vestibules, 34 ft. 3 in. over the body, 8 ft. 5 in. wide over the sills and 11 ft. 11⅝ in. from the rails to the trolley base. The constructional materials are steel underframe, composition wood and metal body, with agasote headlining and bronze interior trim. The main passenger compartment is fitted with Hale & Kilburn cross seats for thirty-six passengers. The seating in the baggage-smoking compartment is somewhat unusual inasmuch as rattan seats are used along the sides in addition to removable slat benches alongside the door. It will be noted also that the upper part of the doors of this compartment is glazed with clear glass, grilling being used to prevent breakage, and that the partition between the two compartments is also of clear glass. The lamps are equipped with inverted bowl shades. The bodies are mounted on 27 M.C.B-2 X trucks with hammered steel axles and Carnegie steel wheels. The motor equipment is of the GE 201-G type. Both Peacock hand and Westinghouse A.M.M. automatic air brakes are employed.



COMBINATION PASSENGER AND BAGGAGE CAR FOR THE CUMBERLAND & WESTERNPORT RAILWAY

Protection of Pit Steps and Columns Against Chipping

The Trussed Concrete Steel Company, Youngstown, Ohio, has recently brought out a form of reinforcement called a curb bar which is designed specifically to protect the edges of concrete steps and columns against chipping or other breakage. In the case of electric railway structures, the new form should prove especially useful for pit steps on which brakeshoes and other heavy parts are liable to fall and do damage. The curb bar is made from a special steel section which is punched and expanded by powerful machinery. The form of the plate is such as to give a neat edge, while the anchorage is integral therewith. The bars are of open hearth steel and are galvanized after forming.

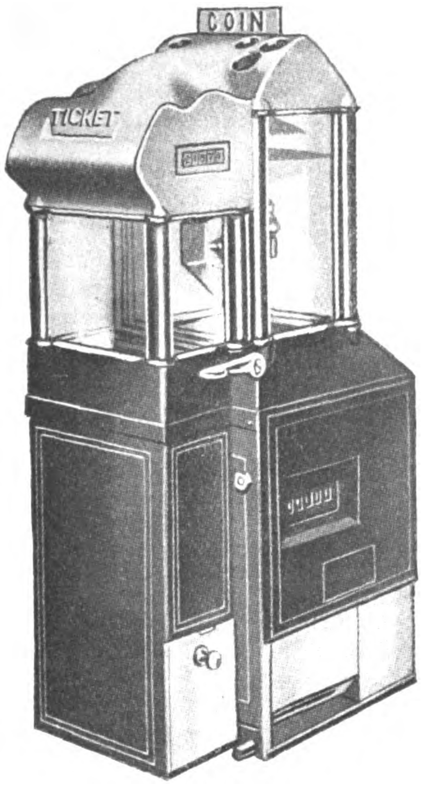
REINFORCING MEMBER

Ticket and Cash Counting Fare Box

An illustrated description in the Electric Railway Journal for March 14 set forth recent developments in recording fare boxes as perfected by the Johnson Fare Box Company, Chicago and New York. This article described in particular the addition of a receptacle for tickets, which includes a cancelling device operated by a small motor. The accompanying illustration shows the most recent improvement to this combination coin and ticket box. A ticket counter has been added so that, as now sold, the combined box will receive and count coins and will receive, cancel and count tickets.



FARE BOX WITH TICKET AND CASH COUNTING MECHANISM

The tickets used are octagonal in shape with dimensions of 1⅜ in. for the shortest diameter and 1½ in. for the longest diameter. They are prepared in strips of the desired length and the strips are scored so that the tickets will separate easily and correctly. It is stated that the cost of these tickets is no greater than for any other tickets. When a passenger inserts even the smallest part of a ticket in the slot, the cancelling rolls engage with the ticket and pull it inward, passing it rapidly between two sets of rolls which cancel it and drop it into an inspection box below. As the ticket is passing through the rolls it operates a unique counting device which gives an accurate registration of each ticket passing through, whether singly or in strips. This ticket cancelling and counting device with its examination box and ticket receptacle below has a capacity for handling more than 1000 tickets before it requires emptying. However, boxes in use never become filled because it is the practice at the end of each trip to remove the tickets from the box and insert them in the trip report envelopes.

The ticket counting and cancelling device is so designed that it will fully cancel and individually count all tickets even though they may be inserted in strips; also the inking rollers are arranged so that a double cancellation is plainly indicated. Some of these boxes have been in actual service since December, 1913. It has been found that the motors give no trouble and so far have required no attention. The felt rollers which carry the ink are especially hard and should last for several years. These rollers require inking at intervals of not less than ninety days.

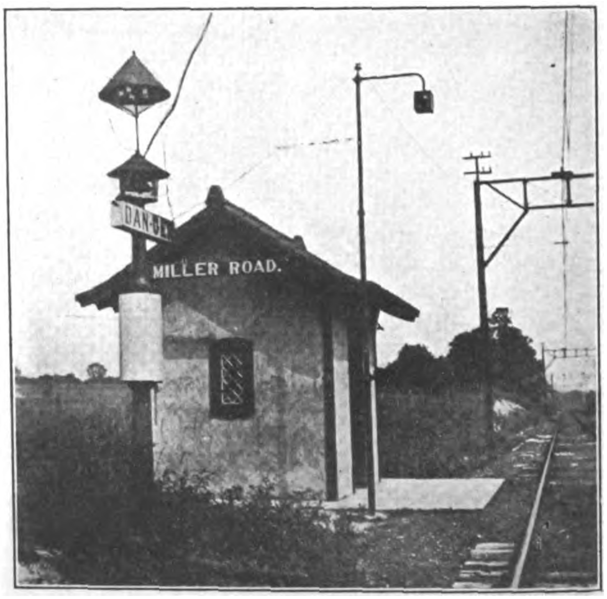
The fare collection methods which are recommended by the Johnson Fare Box Company, in connection with the use of its latest devices, contemplate the use of "clock" registers in the cars and combination ticket and cash counting boxes on the platforms. As fares are received, whether they are tickets or cash, they pass into the inspection receptacles and are then counted and the cash and tickets are available for the conductor, the cash for making change and the tickets for turning in with the trip report. This plan exhibits to the interior of the car the instantaneous count of all fare passengers and insures a prompt count of both tickets and cash as they pass through the fare box. It is thought that this box with its ticket cancelling and counting attachment will be of particular interest to those roads which collect 70 or 80 per cent of their receipts in the form of tickets.

The company has recently moved into a new plant in Chicago, the capacity of which is 2000 boxes every ninety days. The company is now at work on an order of 1000 boxes. The equipment used for the manufacture of the boxes includes a large number of special machines. The boxes are in unit parts so that the parts are interchangeable. The movement of the mechanism in the boxes is effected in all cases by gear transmission, and a great many unique dies, jigs, presses and tools have been evolved to assure uniformity in manufactured parts.

Road Crossing Stop Signals

The Northern Ohio Traction & Light Company, Akron, Ohio, has recently installed a number of road crossing stop signals for the convenience of its passengers. It is expected that these signals will serve to promote safety, aid the motorman in making efficient stops and prove a great convenience to patrons. The signals comprise a small rectangular lantern housing made of ingot iron fitted with two 5⅜-in. green semaphore lenses and wired for three 250-volt lamps. The size of the lens insures a clear indication to the trainmen, and the low drop across the lamp terminals insures a long life.

These signals are mounted on steel poles with mast arms projecting so that the lights are clearly visible to the motormen. As the train approaches the road crossing a prospective passenger closes the lamp circuit through a manually operated self-opening switch, which is released upon receiving a signal from the approaching car. This equipment was furnished by the Nichols-Lintern Company, Cleveland, Ohio. Similar signals are also being used on the Cleveland, Alliance & Mahoning Valley Railroad, and signals of this type are being tested by the Northwestern Pennsylvania Traction Company, Meadville, Pa.



ROAD CROSSING STOP SIGNAL

News of Electric Railways

Court to Pass on Toledo Three-Cent Fare Injunction in September

The application for an injunction to restrain the city of Toledo, Ohio, from enforcing the Schreiber 3-cent ordinance was heard by Judge John M. Killits of the United States District Court on Aug. 14. The Toledo Railways & Light Company filed the application a few days prior to this as supplementary to the petition for a receiver which has been pending in that court for some months.

The court will pass upon the application on Sept. 8. Unless it can be shown by that time that it is possible for the company to operate its cars for 3 cents, without impairment of its securities, the injunction will be granted by the court.

A ruling was made to the effect that the company may cease the operation of its cars at any time, voluntarily, or the city may force the suspension of operation, since all franchises have expired. The court said this would work a hardship upon the citizens, and result in great damage to the business of the city.

When City Solicitor Thurstin objected to the burden being placed on the city of showing the reasonableness and validity of the Schreiber ordinance, the court said that the testimony of Accountant Carl Nau, Cleveland, submitted in the previous hearing of the case last March, unless refuted by the city, is enough to show that 3-cent fare will not pay in Toledo. Judge Killits said in part:

"The only reason why an injunction was not then issued was that the ordinance itself pointed out that it is the duty of the city solicitor to enforce it. By the attitude of the city, the court was led to believe that as soon as the papers could be prepared suit would be filed in common pleas court to ask the court to pass on this question. That burden has been upon the city ever since March 27. At the bottom of all this controversy is the question whether the Schreiber ordinance is reasonable, and it is difficult to conceive that in all this time no court has been asked to pass on this question.

"In this particular case, the court puts the burden on the city of showing that its own ordinance is illegal because the very construction of the ordinance requires that the city solicitor go into court to enforce the ordinance just as soon as the company refuses to obey it. Is it possible that the city intends to occupy the position of dog in the manger forever? If the ordinance is unreasonable the company cannot be held to its terms by the mere fact that it continues to operate. We must have transportation. Then for the city to say that if the company continues to furnish that transportation it thereby accepts terms which may be unreasonable is unconscionable.

"If the city attempts to enforce the ordinance by means of the police, or by inciting the public to be judge and jury and enforce the ordinance itself, without an effort being made in court to test its validity, a federal question is involved and this court has the right to inquire into it. The morals of this community are being impaired by the general understanding that passengers may beat the company out of fares merely by showing 3 cents.

"On Sept. 8 I expect the city to be prepared to meet not only the facts alleged in the supplementary petition, but also the testimony of Carl Nau, which tends to show that the Schreiber ordinance is inoperative because it is unreasonable. Mr. Nau's testimony, if unrefuted, is sufficient to show that 3-cent fare, because of the mileage and the number of unproductive miles of street railway in Toledo, will not give a return, regardless of bonds. The city ought not to have the idea that there is any sacredness about 3-cent fare, and should be prepared at this minute to show that it is reasonable."

Pending the decision of the court the company will continue to operate cars as in the past, accepting the old rate of fare from those who are willing to pay, but refusing 3 cents at all times.

City Solicitor Thurstin said on Aug. 17 that his department had begun to prepare the matter to be presented to Judge Killits. The company offered to open its books to the city, but Mr. Thurstin said that the city would probably not employ an expert to examine the accounts since the Schreiber ordinance became effective. Council does not meet until Aug. 24 and authority for this step could be secured only at that time.

The city will be required to refute the testimony of Carl Nau, who made the examination referred to by Judge Killits. Mr. Nau testified in a former hearing in regard to the rate of fare that would be necessary to meet the requirements. This, at the time, seemed to satisfy the court that the fare was too low, unless it could be refuted by the testimony of other witnesses. No attempt has ever been made at such refutation.

Results of Boston "Safety First" Campaign

In conjunction with the Boston Chamber of Commerce, the Boston (Mass.) Elevated Railway conducted a "safety first" campaign covering part of June and the whole of July, 1914. The features of this campaign were described in this journal at the time of its occurrence, and figures are now available showing the results of the work on the Boston Elevated system and in the streets of the city as a whole.

In the course of the campaign 200,000 "safety first" circulars were distributed to pupils of the public schools of Boston and five adjoining municipalities; 7500 circulars were sent to the teachers of these schools; two exhibition cars with illuminated signs were operated; 55,000 dasher signs, divided into six different sets, were displayed during July; 45,000 clerestory signs elaborating upon the dasher signs were shown in the interiors of cars during the same period and 2700 signs were displayed upon the company's premises. On the cars and premises of the company, 150,000 gummed labels were shown; 3000 placards illustrating automobile and team accidents were distributed among garages and stables in the Boston metropolitan district, and 10,000 placards were distributed to the owners and drivers of vehicles. Six thousand large placards were distributed to the stores throughout the city and suburbs; 100,000 circulars setting forth "safety first" rules were placed with mercantile and industrial establishments, and various other signs and letters were sent out. Fourteen illuminated "safety first" signs were installed at various terminals and stations, and slides calling attention to the campaign were displayed at various moving picture theaters.

Upon solicitation of the Boston Chamber of Commerce and the Boston Elevated Railway, the New York, New Haven & Hartford Railroad installed a large illuminated sign at the main entrance to the South Station in Boston, which handles the largest passenger traffic of any steam railroad terminal in the world. The newspapers of the city of Boston and surrounding towns and cities were liberal in the prominence which they gave to the campaign. Pictures of the exhibition cars and cartoons based upon the slogan "safety first" were shown. Many individual advertisers adopted the slogan for store-window displays. An attempt to secure the interest of employees was made by the exhibition of charts at all rating stations, showing the daily number of accidents in each of six important classes, as compared with the same period in 1913.

On July 1 a printed bulletin was sent to all employees by the Bureaus of Operation and Maintenance announcing the campaign, and on July 16 a bulletin was posted in the carhouses showing the results for the first half of the month. At the end of the month a printed bulletin was sent out to all employees, giving the results of the entire month's campaign and adopting the slogan, "Safety first, last and always."

The following statement shows some of the principal percentage accident decreases over 1913 as figured on the Boston Elevated Railway: Car and vehicle, 22.5; car and person, 15.7; collision of cars, 19.4; alighting, 28.3; boarding, 27.6; derailments, 14.9; total reduction from 1913, 25.3; car accidents, 20.6; passenger accidents, 28.

Figures compiled by the company show that in spite of an increase of passengers carried of 2.9 per cent over July, 1913, there was a decrease of 25.3 per cent in all classes of accidents during the period of the campaign. Forty-three per cent more passengers were carried per passenger accident than in July, 1913, and the car-miles per passenger accident increased 25.8 per cent. In July, 1913, there were eleven clear days, fifteen partly cloudy and five cloudy, compared with eight clear, thirteen partly cloudy and ten cloudy in July, 1914. The total precipitation in the former month was 2.69 in. and in the latter, 2.64 in., and the mean barometer was 29.92 in. and 29.98 in. The company ran 236 more trips in July, 1914, than in July, 1913. The accident figures on the rapid transit lines show little change compared with the previous year's period.

Following are statistics obtained from the Boston Police Department in regard to the number of street accidents during July, 1913, as compared with the same period during the year 1914:

FIRST WEEK	1913	1914
Fatal	9	2
Serious	10	14
Minor	44	27
Total	63	43

SECOND WEEK	1913	1914
Fatal	17	5
Serious	14	19
Minor	30	29
Total	61	53

THIRD WEEK	1913	1914
Fatal	1	6
Serious	11	9
Minor	42	37
Total	54	52

FOURTH WEEK	1913	1914
Fatal	3	5
Serious	18	3
Minor	43	39
Total	64	47

The total accidents of each kind indicate a reduction of 40 per cent in fatal accidents during July, 1914, as compared with July, 1913; a reduction of 11 per cent in serious accidents, and a reduction of 17 per cent in minor accidents. The average of all accidents shows a reduction of 19 per cent for July, 1914, as compared with the same period for last year.

Des Moines Franchise Negotiations

In referring to the franchise negotiations in Des Moines, Ia., Emil G. Schmidt, president of the Des Moines City Railway, is quoted as follows:

"We would rather reach a solution through the City Council than submit the matter to the voters. I have told the City Council that I would negotiate on the basis of the Denver franchise or on a franchise that will make it possible for the city to enforce good service and fix an established fare. The reduced fare in the latter proposition amounts to the same thing as the payment of a fixed sum to the city, as is done in Denver. If the city will not negotiate further, it will be necessary to draw up a new draft and submit it to the voters. If this is done, the franchise would provide for service and fares but not for capitalization."

The City Council on Aug. 13 rejected the franchise presented by Mr. Schmidt, by moving to substitute the first franchise offered by the company, amended, however, as to the amount of capitalization. The motion stipulates that the capitalization shall not be more than $4,762,500 and also that six fares for a quarter be allowed from the time of acceptance of the franchise by the company. Mr. Schmidt is quoted as follows:

"We will not accept any such franchise and will take the matter direct to the people. The company will take steps immediately to have the special election to see how the people stand on this question. That a franchise calling for such a low capitalization and for reduced fares is not acceptable to the company I repeat at this time. We have made every concession but the one which means that we cannot operate at a profit and have reached the point where there is no hope of settling the matter through the City Council."

The capitalization named in the franchise as originally drawn was $5,400,000.

Subway Construction and Equipment Contracts

Edward E. McCall, chairman, and Travis H. Whitney, secretary of the Public Service Commission for the First District, have executed on behalf of the city of New York the contract for the construction of Section 1-A of Route Nos. 4 and 38 of the Seventh Avenue Subway in Manhattan. The contract was awarded to the Rapid Transit Subway Construction Company, the lowest bidder, for $474,244. Section 1 of this subway covers the connection of the new Seventh Avenue Subway with the existing subway at the Battery. The chairman and the secretary have also executed the contract for station finish for certain stations in the Fourth Avenue Subway, Brooklyn, on the extension now being constructed between Forty-third and Eighty-sixth Streets. This contract was recently awarded to the Station Construction Company, Inc., for $251,133. There are six stations on the extension, namely, local stations at Forty-fifth Street, Fifty-third Street, Bay Ridge Avenue and Seventy-ninth Street, and express stations at Fifty-ninth Street and Eighty-sixth Street. The chairman and the secretary have in addition executed a contract recently awarded to the Indianapolis Switch & Frog Company for the supply of certain special work for the Fourth Avenue Subway in Brooklyn.

Future Transportation Needs of Los Angeles

The *Evening Herald*, of Los Angeles, Cal., has been publishing a series of articles by "men who have done things in Los Angeles" in which they give their ideas as to what should be done to insure the future of the city. In the issue of that paper for Aug. 11 Paul Shoup, president of the Pacific Electric Railway, discussed transportation in part as follows:

"More than any other great city in the world, growth in greatness of Los Angeles will be measured by the safety, swiftness and comfort of its urban and interurban transportation systems. To maintain one great central business section for a population of 1,000,000 or perhaps 2,000,000 people, with that population so distributed that each family may have its own vine and fig tree, involves a problem in transportation. The rule is fairly well established that suburban communities may become a part of the daily business life of a city if not further removed than one hour from the center. The army of commuters dwindles rapidly after the hour post is passed. This time element is of greater importance than the fare or the distance; indeed, distance cuts little figure save as it affects the expense and time elements.

"It is essential that the city should maintain a policy that will keep open to the very heart of its business section ways for the suburban and interurban electric railways. Any policy of interference with their service is but one of putting up hurdles for the stranger seeking our gates to jump over; and other gates are open. Lines of travel must be provided that will furnish such easy access to the city's center that one may have a home 35 or 40 miles away and yet be a part of the city's daily business life. But if it is to be done these lines must eventually be free from grade crossings and on rights-of-way devoted to no other purpose. Then Pomona and Santa Ana may both come well within the hour limit. First of all the city must be willing and able to grant such rights as will assure to investors the stability and safety of their investments; and second, its citizens must be willing to pay such rates of fare as will yield a reasonable return upon the investment—what you would want and expect if it were your bank account that was being converted into rails and rights-of-way.

"The Pacific Electric Railway does not at present on all classes of travel, commutation, single and round trip, earn a great deal more than 1 cent a mile. The round trip to the beaches, for example, yields only from 1 cent to 1½ cents a mile, and the individual commutation rates are much below 1 cent a mile where traffic is dense. And if further large investments are to be made to help make this greater city, the rate question, one of sore perplexity to many railways, needs to have the careful and fair consideration of the public; bricks cannot be made without straw, nor railroads operated without adequate revenues.

"The transportation systems of the future will have as its base our present lines, supplemented with subways to the west and elevated roads to the east and south, over which electric trains will be operated without 'let or hindrance' to the city's center, making of Los Angeles County, for a radius of 40 miles around, one great city. How fast transportation development will come upon us will be determined not only by the need but as well by the measure of public confidence and co-operation granted. It would be idle to claim that railways still have any open sesames to treasure houses. The railways must prove their case in advance and the public must stand by them; for the public is most interested after all in their welfare, since without success there cannot be good service, and good service is the making of our southern California."

The Toronto Purchase Deal

The proposed purchase of the property of the Toronto Railway and the Toronto Electric Light Company by the city is regarded as being off. Mayor Hocken would not admit on Aug. 14 that the financial situation was the controlling factor, but on all sides it is agreed that it would be highly inadvisable to perfect the sale in the present state of the money market, particularly as the city has experienced difficulty in obtaining funds to finance work it now has in hand. When asked if the railway and light purchase was off, the Mayor said: "I do not know. I am consulting financial authorities to see what can be done."

The Mayor announced that the Board of Control would further consider West Toronto's transportation problem at a full meeting about Aug. 20. It is likely that the submission of both a motor bus by-law and one for the extension of the Toronto Civic Car Lines will be recommended.

R. C. Harris, commissioner of works of Toronto, has reported to the Board of Control that a transfer system between the Civic Railway and the suburban lines is not feasible.

Kansas City Board of Control Opens Office

The board of control of the Kansas City (Mo.) Railways is established in a suite of offices in the building at Fifteenth Street and Grand Avenue and is arranging for the approval of the specifications and details of construction of the Prospect Avenue extension. It is also investigating the type of car which will be built, details of construction, and power house and distribution questions. A. L. Good, civil engineer, and R. L. Weber, electrical engineer, have been added to the staff. Two engineers will be selected soon to assist the board in gathering data and studying problems of car schedules and service.

Three of the interurban lines definitely favor the site proposed at Eleventh and McGee Streets for the interurban station. Public hearings were to start on Aug. 18, at which interested persons are to be heard in arguments for the various proposed sites.

Low Water Interferes with Operation of Ohio Road.—The Sandusky River has recently been at its lowest stage in years and, owing to a lack of water, the immense hydroelectric power plant south of Fremont, Ohio, which generates power for the Lake Shore Electric Railway, has been unable to operate.

Service Resumed in Goldsboro.—The Goldsboro (N. C.) Street Railway has re-established service on part of its present system. New track will be laid on the section not now in operation and two more cars put in service. The road suspended operation some time ago. In 1913 the property was sold under foreclosure and the receiver discharged.

Inspection of Eastern Properties.—D. F. Fennell, secretary to J. E. Gibson, general superintendent of the Metropolitan Street Railway, Kansas City, Mo., is at present making a tour of some of the principal cities of the Northeast to observe operating conditions and railway practices. He expects to visit Chicago, Milwaukee, Buffalo, Cleveland, Detroit and Toronto.

Municipal Railway Bond Issue Upheld.—The Supreme Court of the State of Washington has handed down a decision upholding the validity of the $35,000 issue of bonds voted recently in Tacoma for municipal railway purposes. The plan is for the city to equip a short line to the section known as the "Tide Flats," over which the Tacoma Railway & Power Company has agreed to operate under conditions summarized previously in the ELECTRIC RAILWAY JOURNAL.

New Jamaica-New York Service.—The management of the Brooklyn (N. Y.) Rapid Transit Company has announced that it expects to have express trains running in a little more than a year over the elevated tracks on Jamaica Avenue and the third tracks of the Kings County elevated line on Fulton Street, Brooklyn, between Park Row, Manhattan, and Grand Street, Jamaica, in thirty-five minutes and for a 5-cent fare. The distance from Manhattan to Jamaica over this route is more than 12 miles. The third tracking of the Kings County elevated line is now under way on the section between Nostrand Avenue and Sackman Street, and the entire work between the East New York loop and the Brooklyn bridge will be done in a year.

Proposed West Side Service in Cleveland.—City Engineer Hoffman has proposed a plan to give the west side of Cleveland, Ohio, rapid transit service, similar to that proposed for the Heights by way of Kingsbury Run. For the purpose of avoiding street and railroad crossings and keeping the cost of construction within bounds, the Cuyahoga Valley and Walworth Run will be utilized. A point near West Sixty-fifth Street could be reached in this way and then the road would follow Clark Avenue to its junction with Lorain Avenue. It could then be continued as far west as desirable. Mr. Hoffman thinks that this should be a part of the Cleveland Railway system. The matter has been referred to Director of Public Service T. L. Sidlo and Street Railway Commissioner Peter Witt.

Strike on Northampton Street Railway.—Sixty-five conductors, motormen, carhouse employees and trackmen of the Northampton (Mass.) Street Railway went on strike on Aug. 18. The disagreement between the men and the company is understood to have arisen from differences in interpretation of the finding of the board of arbitration which recently investigated wage conditions on the road. The men claim that the finding of the board reduced wages by about $3,600 and that the arbitration agreement did not permit a finding for a wage reduction. According to the company's interpretation, the finding of the board awarded compensation to the men on the basis of actual platform time. Present wage schedules run from 23 to 28 cents an hour compared with 21 to 26 cents under the former arrangement. The men desire to be paid for ten hours' work on the basis of nine hours' platform time.

Dorchester Tunnel Bids Opened.—The Boston Transit Commission has opened bids for the construction of the section of the Dorchester subway located in Dewey Square and Summer Street, Boston, and having a length of about 800 ft. The section includes the Dewey Square station, and associated with it are connections with the South Station elevated platforms and provision for quick access to the South Terminal Station of the New York Central and the New Haven systems. The portion of the subway covered by the bids is one of the most important in the city from the standpoint of traffic arrangements. The subway station at Dewey Square will include a lobby 125 ft. long and about 75 ft. wide. Trains now run in the Cambridge subway between Harvard Square and Park Street, Boston, will provide rapid transit to the South Station from Cambridge, Arlington, Watertown, Newton, Waverly and other western suburbs by the extension of the present Boston section of the Cambridge subway under Winter and Summer Streets to Dewey Square. Bids made public by the commission ranged from $673,780 to $749,860. The contract will be awarded later.

Strike in Vincennes.—The Vincennes (Ind.) Traction Company has suspended operations as a result of a strike of a number of its employees and the alleged hostile attitude of members of some twenty-five union labor organizations in that city. S. S. Bush, the managing director of the system, is a Louisville (Ky.) man and returned to Louisville during the latter part of the week ended Aug. 15 after having spent several days in Vincennes. Mr. Bush said that the only question at issue was recognition of the union, in which something less than a score of the fifty trainmen in the company's employ have enrolled. No attempt will be made to operate cars until the company can be assured of sufficient police protection. Meanwhile about thirty of the company's employees, who have refused to join the union, are reporting daily and are on full pay, prepared to take out the cars when conditions warrant the resumption of service. The company has 9 miles of track in Vincennes, which is a city of about 25,000. According to Mr. Bush, most of the employees of the company signed a statement previous to the strike in which they expressed satisfaction with conditions of work and pay.

Financial and Corporate

Recent Financial Tendency

The resumption of international trade relations on a moderate scale on Aug. 19, with the foreign exchange market at rates more nearly approaching normal, was generally looked upon as an augury for good in the near future. War risks which commanded from 30 to 50 per cent ten days ago were quoted on Aug. 19 at 3 to 5 per cent in addition to the general insurance rate of one-fifth of 1 per cent on cargoes. On Aug. 19 sterling exchange was quoted from 4.96 to 4.98, while sixty to ninety-day bills were quoted at 4.88¾, and represented actual transactions.

There has been considerable agitation for the reopening of the stock exchanges, the Boston *News Bureau* saying that such reopening cannot be delayed much longer. The governors of the New York Stock Exchange are said not to have discussed the question of reopening. The committee of governors positively refuses to disclose the volume or character of the daily dealings for cash in securities through the medium of the Clearing House, but it is reported that since the system was inaugurated the daily transactions on several occasions have reached 15,000 shares. In connection with the agitation for reopening the New York Association of Partners of Stock Exchange Firms sent a notice to members on Aug. 19 reviewing present conditions briefly and suggesting that members notify customers that they will accept orders to be executed "at the market" only in moderate amount and for adequate reasons, the association recommending strongly that all orders should have fixed limits; that buying orders should be executed only for those who previously have supplied ample margin, or whose purchases are made for cash, and that stop loss orders be eliminated as far as possible. It was felt that by co-operating along these lines the opening of the exchange would be facilitated and that such a course would render the initial transactions free from violent and erratic fluctuations.

Trading in securities for cash was resumed on the Chicago Stock Exchange on Aug. 14 under a plan similar to that adopted in New York on Aug. 12. In addition members of the Chicago exchange received permission to execute buying and selling orders in their own offices, at prices not below the closing quotation of July 30. The bond market in Chicago is reported at a standstill. Bond houses are said to have recalled all their salesmen. The Montreal exchange has announced that three days' notice will be given before trading is resumed there. The Boston Curb Exchange is open daily from 10 a. m. to 12 m. for the settlement of outstanding contracts, but members have been warned not to trade in stocks or bonds listed on the Boston or other exchanges.

The conference between treasury officials and representative bankers and business men to the number of 150 at Washington on Aug. 14 is regarded as having a stabilizing effect. Views were generally interchanged with the object in mind of guiding the treasury in upholding the credit of the country and in devising means to restore normal conditions in the export trade. The opinion prevailed that there would be no escape from a war tax if the war should continue for any length of time. In connection with the issue of emergency currency it is pointed out that National bank notes hoid a peculiar place in the country's circulation. Unlike either the gold and silver certificates, which are secured dollar for dollar by metal, or the United States legal tender notes, which are secured by a substantial gold reserve fund, they have behind them for the most part, only the credit of the Government in the shape of its bonds. The metal security behind the other notes has a stable value, but how the security behind the national bank notes is liable to impairment was demonstrated in the decline in the price of Government bonds last year. The danger indicated here is from any project which resulted in pyramiding obligations upon a base that is liable to depreciation under adverse circumstances.

On Aug. 18 President Wilson signed the amendment to the Panama Canal act under which foreign-built ships may be admitted to American registry for overseas trade. The measure becomes effective at once. It was reported about the same time that the British Government had informed this Government that it would not interpose any objection to the transfer of German vessels to American registry if assurances and evidence were furnished that the sales of these vessels to Americans were bona fide and not merely for the period of the war between Great Britain and Germany.

The Boston *News Bureau* has prepared the following interesting comparison of the leading traction securities, giving the closing prices of July 30, the 1914 high and the high and low for 1913:

	Close July 30	1914 High	1913 High	1913 Low

Dominion Power & Transmission Company, Ltd.

According to the annual report of the Dominion Power & Transmission Company, Ltd., Hamilton, Ont., Canada, the gross earnings of the company for the year ended Dec. 31, 1913, amounted to $2,737,806. The operating expenses totaled $1,455,993, leaving a net income of $1,281,813. After the transfer of $141,116 to the maintenance and renewal accounts and the payment of bond interest and general interest of $378,172, there were left surplus earnings of $762,525. The combination of this sum with the profit and loss balance for 1912 of $1,005,715, together with the declaration of dividends of $362,378 and the transferal to the reserve account of $450,000, left a profit and loss balance for the year of $955,861.

The report of the company lays particular stress upon what it considers to be a feature of conservatism in accounting: namely, the installation of a reserve for taking care of maintenance and depreciation. Prior to 1913 it was the practice to charge to operating expenses all sums spent on necessary renewals and maintenance, the amount so spent in 1910 being $210,753; in 1911, $224,935, and in 1912, $282,443. In 1913 the board of directors began charging off a substantial percentage of the gross earnings each year, the charge for that year being $442,677. Of this amount $337,269 was actually expended, the balance remaining to the credit of the maintenance and renewal account as a special reserve. This provision was made in addition to the sinking fund for bonds.

Cape Breton Electric Company, Sydney, N. S., Canada.—The gross earnings of the Cape Breton Electric Company for the year ended June 30, 1914, were $373,647, as compared to $373,788 for the year ended June 30, 1913. The net earnings for the present year amounted to $166,308, as compared to $173,045 for the year previous. The interest charges increased during the year from $55,931 to $60,973, sinking and improvement funds decreased from $14,380 to $14,280, and the surplus decreased from $102,734 to $91,055.

Chicago & Milwaukee Electric Railroad, Highwood, Ill.—The resale of the Chicago & Milwaukee Electric Railroad, ordered by the United States Circuit Court of Appeals, was postponed for six months on Aug. 17 by Federal Judge Geiger, on motion of Master in Chancery Charles Morrison. The financial condition caused by the European war is given as the reason for the postponement of this sale.

Cities Service Company, New York, N. Y.—The directors of the Cities Service Company adjourned until Aug. 10 the meeting planned to be held on Aug. 7. At the later date they decided to refer to the executive committee the course to be pursued in regard to dividends, the executive committee being instructed to be prepared to make recommendations at the next directors' meeting, shortly to be held.

Columbus, Delaware & Marion Electric Railroad, Columbus, Ohio.—Suit for $591,146 has been filed in Common Pleas Court against the Columbus, Delaware & Marion Electric

Railroad by the Troy Trust Company. The trust company claims that it is the holder of a mortgage for $500,000 of the Columbus, Marion & Bucyrus Railway, said to be insolvent, and that the Columbus, Delaware & Marion Railroad guaranteed payment.

Fonda, Johnstown & Gloversville Railroad, Gloversville, N. Y.—The Fonda, Johnstown & Gloversville Railroad has deferred the annual dividend on its common stock. Last year the company paid 2 per cent. President J. L. Hees, in a letter to stockholders, says: "The board of directors has not felt justified because of recent events, affecting general financial conditions, in approving the payment at the present time of a dividend on the common stock. Operations for the year ended June 30 show practically the same surplus available for the dividend as in the previous year, but it has been considered advisable to conserve the company's cash resources."

Hocking-Sunday Creek Traction Company, Nelsonville, Ohio.—The Public Utilities Commission of Ohio has authorized the Hocking-Sunday Creek Traction Company to issue $300,000 of first and refunding mortgage twenty-four-year 6 per cent bonds and to execute a promissory note payable in five years or less from the date thereof to the amount of $100,000. The proceeds of the bonds are to be used as follows: $156,200 to be offered in exchange for the present outstanding bonds of the company, and $143,800 to be deposited as collateral, guaranteeing the payment of the principal and interest of the promissory note. The money secured by the delivery of the promissory note is to be used for the completion of the proposed line of interurban railway into Athens, including the equipment of this line with new and modern coaches. The application of the company for permission to issue these securities was noted in the ELECTRIC RAILWAY JOURNAL of Aug. 1.

Keokuk (Ia.) Electric Company.—The directors of the Keokuk Electric Company have declared a dividend of 2 per cent on the $615,000 of common stock, payable on Aug. 15 along with the regular quarterly dividend of 1½ per cent on the $215,000 of 6 per cent cumulative preferred stock. Prior dividends paid in 1914 on the common stock were 2 per cent on Feb. 16 and 1¾ per cent on May 15.

Modesto & Empire Traction Company, Modesto, Cal.—The California Railroad Commission has authorized the Modesto & Empire Traction Company, successor to the Modesto Interurban Railway, to issue 144 shares of capital stock, par value $100. This stock is to be issued to various persons in return for property, cash advanced and other obligations. This line connects Modesto and Empire.

Ocean Shore Railroad, San Francisco, Cal.—According to a decision recently handed down by the Railroad Commission of California, the original cost of the operative property of the Ocean Shore Railroad as of June 30, 1912, was $5,373,668. The total original cost of all properties, according to the engineering department investigation, amounted to $5,656,509, approximately three-quarters of which was made up of three items—land, grading and overhead expenses. The company in its appraisal stated the reproduction value of the operative property to be $6,124,679, but the engineering department in its valuation found this value to be $4,812,084. The company placed the present value of its operative property at $5,807,221, or equal to 94.8 per cent of the reproduction value. The engineering department's valuation showed the present value to be $4,627,319, or 96 per cent of the reproduction value. The total cost of the non-operative property of the company, as ascertained by the engineering department, was $507,890.

Pittsburgh, McKeesport & Westmoreland Railway, McKeesport, Pa.—A suit was recently filed in the Court of Common Pleas of Allegheny County by the Traction Materials Company, New York, asking the court to direct the sale of the Pittsburgh, McKeesport & Westmoreland Railway free and clear of all liens and incumbrances. James B. Secrist is receiver of the company.

Republic Railway & Light Company, New York, N. Y.—The gross earnings of the controlled companies of the Republic Railway & Light Company for the year ended June 30, 1914, were $3,093,848, as compared to $2,844,334 in 1913. The net earnings after the payment of taxes amounted to $1,210,682 for the fiscal year and $1,086,739 for the previous year. During the present year interest and preferred dividend payments amounted to $704,458 and $311,709, as compared to $632,501 and $311,919 respectively during the previous year. The surplus as of June 30, 1914, was $194,515, as compared to a surplus as of June 30, 1913, of $142,319. It is announced that the company will hereafter issue a consolidated statement of earnings for the subsidiary companies, as well as for the parent company.

Riverside Traction Company, Newark, N. J.—The Board of Public Utility Commissioners of New Jersey has refused the application of the Riverside Traction Company for approval of an issue of $132,000 of 5 per cent mortgage bonds, but has approved of the issuance of $51,000 of these bonds. The money is to be used for a new power plant at Burlington.

San Diego Consolidated Gas & Electric Company, San Diego, Cal.—The California Railroad Commission has issued a supplemental order authorizing the San Diego Consolidated Gas & Electric Company to apply the proceeds from the sale of $23,000 of bonds against construction expenditures incurred in the period beginning May 31 and ending Nov. 1, 1914.

San Diego (Cal.) Electric Railway.—A special general meeting of the stockholders of the San Diego Electric Railway has been called for Sept. 30. The purpose of the meeting is to consider a proposition to increase the authorized bonded indebtedness of the company to $10,000,000 by refunding its present outstanding bonded indebtedness and creating an original bonded indebtedness of $10,000,000, and to secure the same and interest thereon by the execution of a deed of trust and mortgage upon its corporate properties. The details of the company's present bonded indebtedness and its application to the California Railroad Commission for permission to create this bonded indebtedness of $10,000,000 was noted in the ELECTRIC RAILWAY JOURNAL of July 11.

Seattle (Wash.) Municipal Railway.—During July, Division "A" of the Seattle Municipal Railway operated at a loss of $1,904, while Division "C" made a profit of $371. Counting the earnings and expenses of both lines the net loss was $1,528. The power bill for Division "A" approximated $670, and the interest on bonded indebtedness $1,125. The power bill of Division "C" amounted to $570. The passenger revenue from Division "A" was $1,482, and the revenue from the same source from Division "C" was $2,065. The freight revenue from Division "C" was $107 and the miscellaneous revenue amounted to $3.38, making a total of $2,176 for Division "C."

Underground Electric Railways, Ltd., London, England.—The London Stock Exchange has admitted for quotation a further issue of $179,000 of 6 per cent income bonds of $100 each of the Underground Electric Railways. The directors of the London Underground Electric Railways have issued a statement to the effect that with the court's sanction the company has become a share and securities holding company. The regular receipts of the company for the first six months of the current year remaining after paying or providing for all expenses would justify the distribution of approximately £60,000 by way of interim dividends on the shares according to their respective rights. The board has decided, however, to defer the payment of dividends until the next annual meeting. The directors of the London General Omnibus Company, which is controlled by the Underground Electric Railways, have declared a dividend of 8 per cent free of income tax on the ordinary shares for the half year ended June 30. Owing to the acquisition of the assets of the General Omnibus Company, the dividend is on capital of £1,600,480, as compared to £1,150,480 last year. An interim dividend on the ordinary shares of the London & Suburban Traction Company, another controlled corporation, has been declared at the rate of 1 per cent per annum for the six months ended June 30. This is the first dividend on the ordinary shares of this company, which was formed in November, 1912.

United Railroads, San Francisco, Cal.—The date set for the hearing in connection with the inquiry into the finances of the United Railroads by the Railroad Commission of California has been postponed until Aug. 24.

United Railways Investment Company, San Francisco, Cal.—The United Railways Investment Company has paid Series "L" of $200,000 of its issue of 6 per cent serial notes, together with interest now due. With this payment there is left $1,100,000 of the original issue. The notes were put out to acquire $3,500,000 of first preferred stock of the United Railroads of San Francisco and are secured by deposit of that stock and by $1,500,000 additional, previously acquired.

Washington-Oregon Corporation, Vancouver, Wash.—A committee composed of Thomas Pitcairn, James D. Windsor, Jr., and Lawrence J. Morris is requesting the deposit of the first and consolidated mortgage twenty-five-year gold 6's of the Washington-Oregon Corporation, dated 1911, due April, 1916, the interest on which was due April 1 and is in default. The interest for July 1 on the $350,000 of Twin City Light & Traction Company first mortgage twenty-five-year gold 6's of 1909, due 1935, also remains unpaid. These bonds are secured on properties formerly owned by the Chehalis Electric & Traction Company and the Centralia Electric & Traction Company. There are also outstanding and possibly in default $65,000 of Lewis County Water Company first 6's of 1909, due 1929, and $40,000 of Centralia Water Company first 6's of 1906, due 1926. The Washington-Oregon Corporation was incorporated in Washington in 1910 and has outstanding $1,266,100 of common stock and $286,400 of preferred stock, the total authorized capital stock being $5,000,000. It has acquired the ownership or control of various local public utilities, including the Vancouver (Wash.) Traction Company, the Twin City Light & Traction Company, Chehalis, Wash., and the Haines Electric Traction Company. The company operates an electric line between Vancouver and Sifton (Vancouver Division) and Centralia and Chehalis (Twin City Division). The appointment of a receiver for the company was noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8.

Dividends Declared

Rochester Railway & Light Company, Rochester, N. Y., 1¼ per cent, quarterly, preferred.

Washington Railway & Electric Company, Washington, D. C., 1¾ per cent, quarterly, common; 1¼ per cent, quarterly, preferred.

Southern Pacific Company, 1½ per cent, quarterly.

Keokuk (Iowa) Electric Company, 1½ per cent, quarterly, preferred; 2 per cent, common.

Traffic and Transportation

Compliance with Service Recommendations in Albany

Seymour Van Santvoord, chairman of the Public Service Commission of the Second District of New York has directed a letter to the United Traction Company, Albany, N. Y., relative to the charges made to the commission against the management of the company, and the recommendations by the commission's electrical expert, Mr. Van Santvoord says:

"With a view to facilitating as far as possible the accomplishment of certain hoped-for improvements in the service of your company in Albany, an interview was had with James F. Hamilton, general manager of the company, a few days ago, in the course of which he was advised of the views of the commission in reference to certain of the recommendations contained in our Mr. Barnes's report under date of June 10, 1914. In confirmation of such oral statement I beg now to advise you that the commission has finally passed upon and decided certain of said recommendations."

The recommendations by Mr. Barnes and decision thereon follow:

1. That it put in proper operating condition the 13.26 miles of track classified in track table as in fair condition. Recommendation adopted with the understanding that the company has given assurance that as soon as the street paving is commenced, it will reconstruct its track on Central Avenue, along Broadway and South Pearl Street.

4. That it provide additional means to prevent a car from running into the river when the draw of the Greenbush bridge is open. Approved and the company is to submit to the commission for its approval such additional safeguards as may be proposed, with the exception that they shall be installed not later than Oct. 1 next.

9. That it comply with the detailed suggestion on page 263 in reference to church hour service. Approved on the understanding that the company is already making a proper compliance and that still further improvements in methods of operation in this respect shall be made.

10. That it furnish a reasonable service during what is known as the theater hours, especially the travel from the theater, and in accordance with the suggestion for this service. Approved, on understanding that the company is already providing additional car service for the accommodation of theatergoers in returning to their homes, and is making a study of the case with a view of such additional service as may be proper.

11. That the company immediately modify its rules in reference to transfers so that a second transfer will be issued to persons on Pine Hills cars to points on the West Albany line, by Quail instead of Lark Street, and on Arbor Hill-Kenwood line to points on the Delaware Avenue line. Approved on the understanding that the company is engaged in the preparation of a coupon transfer arrangement under which passengers will be enabled to ride to destination by the most direct route for one fare. This should be put into effect by Sept. 1.

14. That it rearrange its passenger stops on the basis of rapid transit with the least possible inconvenience to passengers. Approved, with the understanding that compliance by the company shall be made in all cases except where it would be in conflict with city ordinances or franchise requirements; and that it should be operative not later than Nov. 1 next.

17. That it equip all its cars in Albany city with conspicuous route and destination signs illuminated at night. Approved on the company's compliance in the case of all closed cars, regular and extra, to be completed not later than July 1, 1915.

21. That it cause the steps on six of the open cars which are 21 in. or more in height to be lowered, or these cars be withdrawn from the service. Approved, compliance therewith by the company to be made not later than May 1, 1915.

22. That it construct new transformer station, replacing the present North Albany station as near as practical to the center of gravity of the feeder system. Approved, the commission understanding that the company has already made substantial progress in the construction of the proposed new transformer station. The commission expects

that such station shall be sufficiently completed and a portion of its equipment, with a capacity of not less than 1200 kw, shall be installed and put in operation not later than Dec. 15, 1914; the complete installation and rearrangement of the feeder system to be completed by July 1, 1915.

23. That it construct an additional high tension and transmission line between Mechanicville and Watervliet, a distance of 12½ miles. Approved, the commission understanding that the company has already performed a substantial part of the work in constructing the proposed additional high tension line; the commission expects this line shall be completed and put in operation by Sept. 1, 1914.

25. That before Aug. 1, 1914, it notify this commission what it proposes to do before Nov. 1, 1914, in increasing the amount and responsibility of its power supply providing a reasonable "stand-by service."

Compliance with recommendations Nos. 22 and 23 is considered as practically a compliance with recommendation No. 25, except that portion of the latter which refers to "stand-by" service; with the contemplated improvement in the reliability and amount of power supply and the improved methods of utilizing such supply, the matter of the "stand-by" service may be held in abeyance.

After stating the recommendations and the approval of those enumerated, Chairman Van Santvoord concludes:

"The adoption of the above mentioned recommendations is to be considered only as representing the views of the commission upon the particular subjects involved, consideration of and final action upon the remaining recommendations in the report first above mentioned to be made and determined hereafter."

The report of Mr. Barnes and his recommendations in regard to service in Albany were referred to in the ELECTRIC RAILWAY JOURNAL of June 27, page 1478.

Boston-New York Through Trolley Trip

Twenty-five newspaper men left Boston at 8.15 a. m. on Aug. 17 on a special car of the Bay State Street Railway as the company's guests on a through trip to New York, according to the plan outlined in the ELECTRIC RAILWAY JOURNAL of Aug. 15, page 318. Robert S. Goff, vice-president, and E. W. Holst, superintendent of equipment of the Bay State Street Railway, were on hand to speed the party on its journey of 267 miles. The car was in charge of Ralph M. Sparks, general passenger agent of the company. Photographs of the interior and exterior of the car and a cut of the route traversed were presented to each representative of the press soon after starting. The car was tastefully fitted up with wicker chairs in place of the usual cross-seats, as on the New England Street Railway Club convention trip of last fall. In the advertising racks were maps of the route drawn to scale and showing the schedule for the complete round trip. It was planned to pick up various local newspaper men at important cities en route, and the schedule called for a night's lay-over at New London, Conn., going and coming. The New London Business Men's Association entertained the party during these stops and the program included a dinner, automobile rides about the city and boat trips to Fort Griswold. Crews were changed at the boundaries of each system traversed.

The route was from Post-office Square, Boston, through Mattapan, Brockton, and Taunton to Providence, R. I., and Danielson, Conn., over the Boston Elevated Railway, the Bay State Street Railway and Rhode Island Company and thence to New Haven, Conn., via the Shore Line Electric Railway. From New Haven to Stamford the car traversed the lines of the Connecticut Company; from Stamford to New Rochelle, the New York & Stamford Railway handled the car and the final lap of the journey from New Rochelle to New York was over the lines of the New York, Westchester & Boston Railway. The Boston press representatives returned from New York on the 1 a. m. train on Aug. 19. The return trip by trolley followed the same route as the going journey, New York newspaper men being the guests.

To facilitate travel over this route by vacation tourists, the Bay State Street Railway has prepared two folders describing the trip from each starting point, with fares, running times and local leaving times in tabular form, and containing maps of Boston, New York and the intermediate territory, with running commentary upon the principal features of interest en route. The company sells through tickets to points en route, the fare from Boston to New York being $3.75. Tickets may also be purchased at Providence, Norwich, New London, New Haven and New York. In addition to the general information in the folders, data bearing upon hotels en route are included.

The schedule between Boston and New York on Aug. 17-18, follows:

Leave Boston (Post-office Square)	8:00 a.m.
Arrive Brockton	9:50 a.m.
Leave Brockton	9:50 a.m.
Arrive Providence	12:15 p.m.
Leave Providence	12:30 p.m.
Arrive Norwich	4:30 p.m.
Leave Norwich	4:45 p.m.
Arrive New London	5:45 p.m.

Leave New London August 18	8:15 a.m.
Arrive New Haven	11:33 a.m.
Leave New Haven	11:45 a.m.
Arrive Bridgeport	1:45 p.m
Leave Bridgeport	2:00 p.m.
Arrive Stamford	4:25 p.m.
Leave Stamford	4:30 p.m.
Arrive 133d Street, New York	6:45 p.m.

The schedule between New York and Boston on Aug. 19-20, follows:

Leave New York (133d Street)	8:30 a.m.
Arrive Stamford	10:45 a.m.
Leave Stamford	11:00 a.m.
Arrive Bridgeport	1:25 p.m.
Leave Bridgeport	1:30 p.m.
Arrive New Haven	3:30 p.m
Leave New Haven	3:45 p.m.
Arrive New London	7:00 p.m.

Leave New London Aug. 20	8:15 a.m.
Arrive Norwich	9:15 a m.
Leave Norwich	9:15 a.m.
Arrive Providence	1:15 p.m.
Leave Providence	1:30 p.m.
Arrive Brockton	4:00 p.m.
Leave Brockton	4:00 p.m.
Arrive Boston (Post-office Square)	5:50 p.m.

Front-End Collectors in San Francisco

The rush-hour traffic problems in San Francisco are aggravated by the fact that at the close of business hours, when a very large number of passengers desire to board cars at the same time and place, the travel centers chiefly on two or three trunk lines. With no subway or elevated roads, the only relief is to run the cars very close together. This reduces the problem largely to a question of speed in loading, and with pay-as-you-enter cars considerable time is lost on account of congestion at the rear end.

This condition has been very materially improved by the adoption of the practice followed by the Metropolitan Street Railway, Kansas City, Mo., for some time of stationing a man at each important street intersection, who collects fares and allows passengers to enter at the motorman's gate. The same number of passengers can thus get into the car by the front way more quickly than they could by the rear entrance even if the latter were not crowded. The "station conductor" stands beside the track where the forward ends of the cars come to a stop. He makes change and collects fares as the car approaches, issues transfers if desired, and assists passengers to step aboard. The motorman gets his "go ahead" signal from the "station conductor," as the latter can see the rear steps better than the conductor.

The extra men are required at only a few points in the heart of the business district and are on duty for only about an hour in the evening, but this expedient very materially relieves the crowding of the rear platform and allows the cars to make much better time along this part of the line. The results under this system in Kansas City were reviewed in the ELECTRIC RAILWAY JOURNAL of Feb. 14, 1914, page 383.

Hearing on Missouri Fare Case Postponed.—The Public Service Commission of Missouri has postponed until Sept. 25 the hearing on the question of reduced rates on the Kansas City, Clay County & St. Joseph Railway.

Joint Grain Rates.—The Northern Electric Railway, Chico, Cal., has completed arrangements with the Southern Pacific

Financial and Corporate

Recent Financial Tendency

The resumption of international trade relations on a moderate scale on Aug. 19, with the foreign exchange market at rates more nearly approaching normal, was generally looked upon as an augury for good in the near future. War risks which commanded from 30 to 50 per cent ten days ago were quoted on Aug. 19 at 3 to 5 per cent in addition to the general insurance rate of one-fifth of 1 per cent on cargoes. On Aug. 19 sterling exchange was quoted from 4.96 to 4.98, while sixty to ninety-day bills were quoted at 4.88¾, and represented actual transactions.

There has been considerable agitation for the reopening of the stock exchanges, the Boston *News Bureau* saying that such reopening cannot be delayed much longer. The governors of the New York Stock Exchange are said not to have discussed the question of reopening. The committee of governors positively refuses to disclose the volume or character of the daily dealings for cash in securities through the medium of the Clearing House, but it is reported that since the system was inaugurated the daily transactions on several occasions have reached 15,000 shares. In connection with the agitation for reopening the New York Association of Partners of Stock Exchange Firms sent a notice to members on Aug. 19 reviewing present conditions briefly and suggesting that members notify customers that they will accept orders to be executed "at the market" only in moderate amount and for adequate reasons, the association recommending strongly that all orders should have fixed limits; that buying orders should be executed only for those who previously have supplied ample margin, or whose purchases are made for cash, and that stop loss orders be eliminated as far as possible. It was felt that by co-operating along these lines the opening of the exchange would be facilitated and that such a course would render the initial transactions free from violent and erratic fluctuations.

Trading in securities for cash was resumed on the Chicago Stock Exchange on Aug. 14 under a plan similar to that adopted in New York on Aug. 12. In addition members of the Chicago exchange received permission to execute buying and selling orders in their own offices, at prices not below the closing quotation of July 30. The bond market in Chicago is reported at a standstill. Bond houses are said to have recalled all their salesmen. The Montreal exchange has announced that three days' notice will be given before trading is resumed there. The Boston Curb Exchange is open daily from 10 a. m. to 12 m. for the settlement of outstanding contracts, but members have been warned not to trade in stocks or bonds listed on the Boston or other exchanges.

The conference between treasury officials and representative bankers and business men to the number of 150 at Washington on Aug. 14 is regarded as having a stabilizing effect. Views were generally interchanged with the object in mind of guiding the treasury in upholding the credit of the country and in devising means to restore normal conditions in the export trade. The opinion prevailed that there would be no escape from a war tax if the war should continue for any length of time. In connection with the issue of emergency currency it is pointed out that National bank notes hold a peculiar place in the country's circulation. Unlike either the gold and silver certificates, which are secured dollar for dollar by metal, or the United States legal tender notes, which are secured by a substantial gold reserve fund, they have behind them for the most part, only the credit of the Government in the shape of its bonds. The metal security behind the other notes has a stable value, but how the security behind the national bank notes is liable to impairment was demonstrated in the decline in the price of Government bonds last year. The danger indicated here is from any project which resulted in pyramiding obligations upon a base that is liable to depreciation under adverse circumstances.

On Aug. 18 President Wilson signed the amendment to the Panama Canal act under which foreign-built ships may be admitted to American registry for overseas trade. The measure becomes effective at once. It was reported about the same time that the British Government had informed this Government that it would not interpose any objection to the transfer of German vessels to American registry if assurances and evidence were furnished that the sales of these vessels to Americans were bona fide and not merely for the period of the war between Great Britain and Germany.

The Boston *News Bureau* has prepared the following interesting comparison of the leading traction securities, giving the closing prices of July 30, the 1914 high and the high and low for 1913:

	Close July 30	1914 High	1913 High	1913 Low

Dominion Power & Transmission Company, Ltd.

According to the annual report of the Dominion Power & Transmission Company, Ltd., Hamilton, Ont., Canada, the gross earnings of the company for the year ended Dec. 31, 1913, amounted to $2,737,806. The operating expenses totaled $1,455,993, leaving a net income of $1,281,813. After the transfer of $141,116 to the maintenance and renewal accounts and the payment of bond interest and general interest of $378,172, there were left surplus earnings of $762,525. The combination of this sum with the profit and loss balance for 1912 of $1,005,715, together with the declaration of dividends of $362,378 and the transferal to the reserve account of $450,000, left a profit and loss balance for the year of $955,861.

The report of the company lays particular stress upon what it considers to be a feature of conservatism in accounting: namely, the installation of a reserve for taking care of maintenance and depreciation. Prior to 1913 it was the practice to charge to operating expenses all sums spent on necessary renewals and maintenance, the amount so spent in 1910 being $210,753; in 1911, $224,935, and in 1912, $282,443. In 1913 the board of directors began charging off a substantial percentage of the gross earnings each year, the charge for that year being $442,677. Of this amount $337,269 was actually expended, the balance remaining to the credit of the maintenance and renewal account as a special reserve. This provision was made in addition to the sinking fund for bonds.

Cape Breton Electric Company, Sydney, N. S., Canada.—The gross earnings of the Cape Breton Electric Company for the year ended June 30, 1914, were $373,647, as compared to $373,788 for the year ended June 30, 1913. The net earnings for the present year amounted to $166,308, as compared to $173,045 for the year previous. The interest charges increased during the year from $55,931 to $60,973, sinking and improvement funds decreased from $14,380 to $14,280, and the surplus decreased from $102,734 to $91,055.

Chicago & Milwaukee Electric Railroad, Highwood, Ill.—The resale of the Chicago & Milwaukee Electric Railroad, ordered by the United States Circuit Court of Appeals, was postponed for six months on Aug. 17 by Federal Judge Geiger, on motion of Master in Chancery Charles Morrison. The financial condition caused by the European war is given as the reason for the postponement of this sale.

Cities Service Company, New York, N. Y.—The directors of the Cities Service Company adjourned until Aug. 10 the meeting planned to be held on Aug. 7. At the later date they decided to refer to the executive committee the course to be pursued in regard to dividends, the executive committee being instructed to be prepared to make recommendations at the next directors' meeting, shortly to be held.

Columbus, Delaware & Marion Electric Railroad, Columbus, Ohio.—Suit for $591,146 has been filed in Common Pleas Court against the Columbus, Delaware & Marion Electric

Railroad by the Troy Trust Company. The trust company claims that it is the holder of a mortgage for $500,000 of the Columbus, Marion & Bucyrus Railway, said to be insolvent, and that the Columbus, Delaware & Marion Railroad guaranteed payment.

Fonda, Johnstown & Gloversville Railroad, Gloversville, N. Y.—The Fonda, Johnstown & Gloversville Railroad has deferred the annual dividend on its common stock. Last year the company paid 2 per cent. President J. L. Hees, in a letter to stockholders, says: "The board of directors has not felt justified because of recent events, affecting general financial conditions, in approving the payment at the present time of a dividend on the common stock. Operations for the year ended June 30 show practically the same surplus available for the dividend as in the previous year, but it has been considered advisable to conserve the company's cash resources."

Hocking-Sunday Creek Traction Company, Nelsonville, Ohio.—The Public Utilities Commission of Ohio has authorized the Hocking-Sunday Creek Traction Company to issue $300,000 of first and refunding mortgage twenty-four-year 6 per cent bonds and to execute a promissory note payable in five years or less from the date thereof to the amount of $100,000. The proceeds of the bonds are to be used as follows: $156,200 to be offered in exchange for the present outstanding bonds of the company, and $143,800 to be deposited as collateral, guaranteeing the payment of the principal and interest of the promissory note. The money secured by the delivery of the promissory note is to be used for the completion of the proposed line of interurban railway into Athens, including the equipment of this line with new and modern coaches. The application of the company for permission to issue these securities was noted in the ELECTRIC RAILWAY JOURNAL of Aug. 1.

Keokuk (Ia.) Electric Company.—The directors of the Keokuk Electric Company have declared a dividend of 2 per cent on the $615,000 of common stock, payable on Aug. 15 along with the regular quarterly dividend of 1½ per cent on the $215,000 of 6 per cent cumulative preferred stock. Prior dividends paid in 1914 on the common stock were 2 per cent on Feb. 16 and 1¾ per cent on May 15.

Modesto & Empire Traction Company, Modesto, Cal.—The California Railroad Commission has authorized the Modesto & Empire Traction Company, successor to the Modesto Interurban Railway, to issue 144 shares of capital stock, par value $100. This stock is to be issued to various persons in return for property, cash advanced and other obligations. This line connects Modesto and Empire.

Ocean Shore Railroad, San Francisco, Cal.—According to a decision recently handed down by the Railroad Commission of California, the original cost of the operative property of the Ocean Shore Railroad as of June 30, 1912, was $5,373,668. The total original cost of all properties, according to the engineering department investigation, amounted to $5,656,509, approximately three-quarters of which was made up of three items—land, grading and overhead expenses. The company in its appraisal stated the reproduction value of the operative property to be $6,124,679, but the engineering department in its valuation found this value to be $4,812,084. The company placed the present value of its operative property at $5,807,221, or equal to 94.8 per cent of the reproduction value. The engineering department's valuation showed the present value to be $4,627,319, or 96 per cent of the reproduction value. The total cost of the non-operative property of the company, as ascertained by the engineering department, was $507,890.

Pittsburgh, McKeesport & Westmoreland Railway, McKeesport, Pa.—A suit was recently filed in the Court of Common Pleas of Allegheny County by the Traction Materials Company, New York, asking the court to direct the sale of the Pittsburgh, McKeesport & Westmoreland Railway free and clear of all liens and incumbrances. James B. Secrist is receiver of the company.

Republic Railway & Light Company, New York, N. Y.—The gross earnings of the controlled companies of the Republic Railway & Light Company for the year ended June 30, 1914, were $3,093,848, as compared to $2,844,334 in 1913. The net earnings after the payment of taxes amounted to $1,210,682 for the fiscal year and $1,086,739 for the previous year. During the present year interest and preferred dividend payments amounted to $704,458 and $311,709, as compared to $632,501 and $311,919 respectively during the previous year. The surplus as of June 30, 1914, was $194,515, as compared to a surplus as of June 30, 1913, of $142,319. It is announced that the company will hereafter issue a consolidated statement of earnings for the subsidiary companies, as well as for the parent company.

Riverside Traction Company, Newark, N. J.—The Board of Public Utility Commissioners of New Jersey has refused the application of the Riverside Traction Company for approval of an issue of $132,000 of 5 per cent mortgage bonds, but has approved of the issuance of $51,000 of these bonds. The money is to be used for a new power plant at Burlington.

San Diego Consolidated Gas & Electric Company, San Diego, Cal.—The California Railroad Commission has issued a supplemental order authorizing the San Diego Consolidated Gas & Electric Company to apply the proceeds from the sale of $23,000 of bonds against construction expenditures incurred in the period beginning May 31 and ending Nov. 1, 1914.

San Diego (Cal.) Electric Railway.—A special general meeting of the stockholders of the San Diego Electric Railway has been called for Sept. 30. The purpose of the meeting is to consider a proposition to increase the authorized bonded indebtedness of the company to $10,000,000 by refunding its present outstanding bonded indebtedness and creating an original bonded indebtedness of $10,000,000, and to secure the same and interest thereon by the execution of a deed of trust and mortgage upon its corporate properties. The details of the company's present bonded indebtedness and its application to the California Railroad Commission for permission to create this bonded indebtedness of $10,000,000 was noted in the ELECTRIC RAILWAY JOURNAL of July 11.

Seattle (Wash.) Municipal Railway.—During July, Division "A" of the Seattle Municipal Railway operated at a loss of $1,904, while Division "C" made a profit of $371. Counting the earnings and expenses of both lines the net loss was $1,528. The power bill for Division "A" approximated $670, and the interest on bonded indebtedness $1,125. The power bill of Division "C" amounted to $570. The passenger revenue from Division "A" was $1,482, and the revenue from the same source from Division "C" was $2,065. The freight revenue from Division "C" was $107 and the miscellaneous revenue amounted to $3.38, making a total of $2,176 for Division "C."

Underground Electric Railways, Ltd., London, England.—The London Stock Exchange has admitted for quotation a further issue of $179,000 of 6 per cent income bonds of $100 each of the Underground Electric Railways. The directors of the London Underground Electric Railways have issued a statement to the effect that with the court's sanction the company has become a share and securities holding company. The regular receipts of the company for the first six months of the current year remaining after paying or providing for all expenses would justify the distribution of approximately £60,000 by way of interim dividends on the shares according to their respective rights. The board has decided, however, to defer the payment of dividends until the next annual meeting. The directors of the London General Omnibus Company, which is controlled by the Underground Electric Railways, have declared a dividend of 8 per cent free of income tax on the ordinary shares for the half year ended June 30. Owing to the acquisition of the assets of the General Omnibus Company, the dividend is on capital of £1,600,480, as compared to £1,150,480 last year. An interim dividend on the ordinary shares of the London & Suburban Traction Company, another controlled corporation, has been declared at the rate of 1 per cent per annum for the six months ended June 30. This is the first dividend on the ordinary shares of this company, which was formed in November, 1912.

United Railroads, San Francisco, Cal.—The date set for the hearing in connection with the inquiry into the finances of the United Railroads by the Railroad Commission of California has been postponed until Aug. 24.

United Railways Investment Company, San Francisco, Cal.—The United Railways Investment Company has paid Series "L" of $200,000 of its issue of 6 per cent serial notes, together with interest now due. With this payment there is left $1,100,000 of the original issue. The notes were put out to acquire $3,500,000 of first preferred stock of the United Railroads of San Francisco and are secured by deposit of that stock and by $1,500,000 additional, previously acquired.

Washington-Oregon Corporation, Vancouver, Wash.—A committee composed of Thomas Pitcairn, James D. Windsor, Jr., and Lawrence J. Morris is requesting the deposit of the first and consolidated mortgage twenty-five-year gold 6's of the Washington-Oregon Corporation, dated 1911, due April, 1916, the interest on which was due April 1 and is in default. The interest for July 1 on the $350,000 of Twin City Light & Traction Company first mortgage twenty-five-year gold 6's of 1909, due 1935, also remains unpaid. These bonds are secured on properties formerly owned by the Chehalis Electric & Traction Company and the Centralia Electric & Traction Company. There are also outstanding and possibly in default $65,000 of Lewis County Water Company first 6's of 1909, due 1929, and $40,000 of Centralia Water Company first 6's of 1906, due 1926. The Washington-Oregon Corporation was incorporated in Washington in 1910 and has outstanding $1,266,100 of common stock and $286,400 of preferred stock, the total authorized capital stock being $5,000,000. It has acquired the ownership or control of various local public utilities, including the Vancouver (Wash.) Traction Company, the Twin City Light & Traction Company, Chehalis, Wash., and the Haines Electric Traction Company. The company operates an electric line between Vancouver and Sifton (Vancouver Division) and Centralia and Chehalis (Twin City Division). The appointment of a receiver for the company was noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8.

Dividends Declared

Rochester Railway & Light Company, Rochester, N. Y., 1¼ per cent, quarterly, preferred.

Washington Railway & Electric Company, Washington, D. C., 1¾ per cent, quarterly, common; 1¼ per cent, quarterly, preferred.

Southern Pacific Company, 1½ per cent, quarterly.

Keokuk (Iowa) Electric Company, 1½ per cent, quarterly, preferred; 2 per cent, common.

Traffic and Transportation

Compliance with Service Recommendations in Albany

Seymour Van Santvoord, chairman of the Public Service Commission of the Second District of New York has directed a letter to the United Traction Company, Albany, N. Y., relative to the charges made to the commission against the management of the company, and the recommendations by the commission's electrical expert, Mr. Van Santvoord says:

"With a view to facilitating as far as possible the accomplishment of certain hoped-for improvements in the service of your company in Albany, an interview was had with James F. Hamilton, general manager of the company, a few days ago, in the course of which he was advised of the views of the commission in reference to certain of the recommendations contained in our Mr. Barnes's report under date of June 10, 1914. In confirmation of such oral statement I beg now to advise you that the commission has finally passed upon and decided certain of said recommendations."

The recommendations by Mr. Barnes and decision thereon follow:

1. That it put in proper operating condition the 13.26 miles of track classified in track table as in fair condition. Recommendation adopted with the understanding that the company has given assurance that as soon as the street paving is commenced, it will reconstruct its track on Central Avenue, along Broadway and South Pearl Street.

4. That it provide additional means to prevent a car from running into the river when the draw of the Greenbush bridge is open. Approved and the company is to submit to the commission for its approval such additional safeguards as may be proposed, with the exception that they shall be installed not later than Oct. 1 next.

9. That it comply with the detailed suggestion on page 263 in reference to church hour service. Approved on the understanding that the company is already making a proper compliance and that still further improvements in methods of operation in this respect shall be made.

10. That it furnish a reasonable service during what is known as the theater hours, especially the travel from the theater, and in accordance with the suggestion for this service. Approved, on understanding that the company is already providing additional car service for the accommodation of theatergoers in returning to their homes, and is making a study of the case with a view of such additional service as may be proper.

11. That the company immediately modify its rules in reference to transfers so that a second transfer will be issued to persons on Pine Hills cars to points on the West Albany line, by Quail instead of Lark Street, and on Arbor Hill-Kenwood line to points on the Delaware Avenue line. Approved on the understanding that the company is engaged in the preparation of a coupon transfer arrangement under which passengers will be enabled to ride to destination by the most direct route for one fare. This should be put into effect by Sept. 1.

14. That it rearrange its passenger stops on the basis of rapid transit with the least possible inconvenience to passengers. Approved, with the understanding that compliance by the company shall be made in all cases except where it would be in conflict with city ordinances or franchise requirements; and that it should be operative not later than Nov. 1 next.

17. That it equip all its cars in Albany city with conspicuous route and destination signs illuminated at night. Approved on the company's compliance in the case of all closed cars, regular and extra, to be completed not later than July 1, 1915.

21. That it cause the steps on six of the open cars which are 21 in. or more in height to be lowered, or these cars be withdrawn from the service. Approved, compliance therewith by the company to be made not later than May 1, 1915.

22. That it construct new transformer station, replacing the present North Albany station as near as practical to the center of gravity of the feeder system. Approved, the commission understanding that the company has already made substantial progress in the construction of the proposed new transformer station. The commission expects

that such station shall be sufficiently completed and a portion of its equipment, with a capacity of not less than 1200 kw, shall be installed and put in operation not later than Dec. 15, 1914; the complete installation and rearrangement of the feeder system to be completed by July 1, 1915.

23. That it construct an additional high tension and transmission line between Mechanicville and Watervliet, a distance of 12½ miles. Approved, the commission understanding that the company has already performed a substantial part of the work in constructing the proposed additional high tension line; the commission expects this line shall be completed and put in operation by Sept. 1, 1914.

25. That before Aug. 1, 1914, it notify this commission what it proposes to do before Nov. 1, 1914, in increasing the amount and responsibility of its power supply providing a reasonable "stand-by service."

Compliance with recommendations Nos. 22 and 23 is considered as practically a compliance with recommendation No. 25, except that portion of the latter which refers to "stand-by" service; with the contemplated improvement in the reliability and amount of power supply and the improved methods of utilizing such supply, the matter of the "stand-by" service may be held in abeyance.

After stating the recommendations and the approval of those enumerated, Chairman Van Santvoord concludes:

"The adoption of the above mentioned recommendations is to be considered only as representing the views of the commission upon the particular subjects involved, consideration of and final action upon the remaining recommendations in the report first above mentioned to be made and determined hereafter."

The report of Mr. Barnes and his recommendations in regard to service in Albany were referred to in the ELECTRIC RAILWAY JOURNAL of June 27, page 1478.

Boston-New York Through Trolley Trip

Twenty-five newspaper men left Boston at 8.15 a. m. on Aug. 17 on a special car of the Bay State Street Railway as the company's guests on a through trip to New York, according to the plan outlined in the ELECTRIC RAILWAY JOURNAL of Aug. 15, page 318. Robert S. Goff, vice-president, and E. W. Holst, superintendent of equipment of the Bay State Street Railway, were on hand to speed the party on its journey of 267 miles. The car was in charge of Ralph M. Sparks, general passenger agent of the company. Photographs of the interior and exterior of the car and a cut of the route traversed were presented to each representative of the press soon after starting. The car was tastefully fitted up with wicker chairs in place of the usual cross-seats, as on the New England Street Railway Club convention trip of last fall. In the advertising racks were maps of the route drawn to scale and showing the schedule for the complete round trip. It was planned to pick up various local newspaper men at important cities en route, and the schedule called for a night's lay-over at New London, Conn., going and coming. The New London Business Men's Association entertained the party during these stops and the program included a dinner, automobile rides about the city and boat trips to Fort Griswold. Crews were changed at the boundaries of each system traversed.

The route was from Post-office Square, Boston, through Mattapan, Brockton, and Taunton to Providence, R. I., and Danielson, Conn., over the Boston Elevated Railway, the Bay State Street Railway and Rhode Island Company and thence to New Haven, Conn., via the Shore Line Electric Railway. From New Haven to Stamford the car traversed the lines of the Connecticut Company; from Stamford to New Rochelle, the New York & Stamford Railway handled the car and the final lap of the journey from New Rochelle to New York was over the lines of the New York, Westchester & Boston Railway. The Boston press representatives returned from New York on the 1 a. m. train on Aug. 19. The return trip by trolley followed the same route as the going journey, New York newspaper men being the guests.

To facilitate travel over this route by vacation tourists, the Bay State Street Railway has prepared two folders describing the trip from each starting point, with fares, running times and local leaving times in tabular form, and containing maps of Boston, New York and the intermediate territory, with running commentary upon the principal features of interest en route. The company sells through tickets to points en route, the fare from Boston to New York being $3.75. Tickets may also be purchased at Providence, Norwich, New London, New Haven and New York. In addition to the general information in the folders, data bearing upon hotels en route are included.

The schedule between Boston and New York on Aug. 17-18, follows:

Leave Boston (Post-office Square)	8:00 a.m.
Arrive Brockton	9:50 a.m.
Leave Brockton	9:50 a.m.
Arrive Providence	12:15 p.m.
Leave Providence	12:30 p.m.
Arrive Norwich	4:30 p.m.
Leave Norwich	4:45 p.m
Arrive New London	5:45 p.m.

Leave New London August 18	8:15 a.m.
Arrive New Haven	11:33 a.m.
Leave New Haven	11:45 a.m.
Arrive Bridgeport	1:45 p.m
Leave Bridgeport	2:00 p.m.
Arrive Stamford	4:25 p.m.
Leave Stamford	4:30 p.m.
Arrive 133d Street, New York	6:45 p.m.

The schedule between New York and Boston on Aug. 19-20, follows:

Leave New York (133d Street)	8:30 a.m.
Arrive Stamford	10:45 a.m.
Leave Stamford	11:00 a.m.
Arrive Bridgeport	1:25 p.m.
Leave Bridgeport	1:30 p.m.
Arrive New Haven	3:30 p.m
Leave New Haven	3:45 p.m.
Arrive New London	7:00 p.m.

Leave New London Aug. 20	8:15 a.m.
Arrive Norwich	9:15 a m.
Leave Norwich	9:15 a.m.
Arrive Providence	1:15 p.m.
Leave Providence	1:30 p.m.
Arrive Brockton	4:00 p.m.
Leave Brockton	4:00 p.m.
Arrive Boston (Post-office Square)	5:50 p.m.

Front-End Collectors in San Francisco

The rush-hour traffic problems in San Francisco are aggravated by the fact that at the close of business hours, when a very large number of passengers desire to board cars at the same time and place, the travel centers chiefly on two or three trunk lines. With no subway or elevated roads, the only relief is to run the cars very close together. This reduces the problem largely to a question of speed in loading, and with pay-as-you-enter cars considerable time is lost on account of congestion at the rear end.

This condition has been very materially improved by the adoption of the practice followed by the Metropolitan Street Railway, Kansas City, Mo., for some time of stationing a man at each important street intersection, who collects fares and allows passengers to enter at the motorman's gate. The same number of passengers can thus get into the car by the front way more quickly than they could by the rear entrance even if the latter were not crowded. The "station conductor" stands beside the track where the forward ends of the cars come to a stop. He makes change and collects fares as the car approaches, issues transfers if desired, and assists passengers to step aboard. The motorman gets his "go ahead" signal from the "station conductor," as the latter can see the rear steps better than the conductor.

The extra men are required at only a few points in the heart of the business district and are on duty for only about an hour in the evening, but this expedient very materially relieves the crowding of the rear platform and allows the cars to make much better time along this part of the line. The results under this system in Kansas City were reviewed in the ELECTRIC RAILWAY JOURNAL of Feb. 14, 1914, page 383.

Hearing on Missouri Fare Case Postponed.—The Public Service Commission of Missouri has postponed until Sept. 25 the hearing on the question of reduced rates on the Kansas City, Clay County & St. Joseph Railway.

Joint Grain Rates.—The Northern Electric Railway, Chico, Cal., has completed arrangements with the Southern Pacific

Company for through rates on grain on all points on the lines to Port Costa. These rates are the same as those applying to Port Costa via the Southern Pacific lines.

Arbitration Fails at Pittsburg, Kan.—Conferences between the strikers' committee and the officials of the Joplin & Pittsburg Railway, arranged by committees of the Pittsburg trade council and the chamber of commerce, have failed to bring about a settlement of the strike of the employees which has been in progress for some time.

Near-Side Stop in New York.—Mayor Mitchel of New York has signed the ordinance which provides that street cars shall stop at the near side of the street. It is announced that the street cleaning department will co-operate in helping to make near-side operation a success by keeping street intersections clean. The ordinance will go into effect on Sept. 1.

Old Transfers Tendered on Ohio Roads.—On July 22 the Northern Ohio Traction & Light Company, Akron, Ohio, put in use a new style of transfer in the cities and towns in which it operates local lines. It is stated that on that day an astonishing number of old transfers were tendered for fare. The passengers are said to have accepted the situation with a grin when the facts were explained to them and the new transfers were displayed.

Record Illinois Traction Excursion Traffic.—The Illinois Traction System, Peoria, Ill., brought more than 2500 people into Peoria on a recent Sunday from Springfield, Decatur, Bloomington, Lincoln and intermediate cities and towns. A special rate of $1 was made, which included a trip up the Illinois River to Chillicothe on the steamer *David Swaim.* Thirty cars were required to carry the excursionists, who arrived in Peoria about noon and left at 8 p. m. Fifteen trains were dispatched in an hour and a half.

Opportunities for Young Electrical Men.—"The Young Man and the Electrical Industry" is the title of an illustrated story written by James H. Collins for the *Scientific American,* and reprinted and issued by the Westinghouse Electric & Manufacturing Company. The story contains a great deal of information regarding the Westinghouse organization and exemplifies the different lines in which a young man may direct his activities, especially in the works of this company. The company announces that it will supply a copy to anyone interested in the development of young men.

Accidents on Cleveland Suburban Lines.—Two serious accidents occurred recently on electric railways running out of Cleveland. The first was on the Cleveland, Painesville & Ashtabula road, on Aug. 9, when a limited and a local car collided head-on 2 miles east of Painesville. Seven persons, including one of the motormen and one of the conductors, were injured. The other accident occurred on the Northern Ohio Traction & Light Company's line, near Bedford, on Aug. 11. This was a head-on collision of a passenger and a baggage car. Eleven persons were injured seriously and several others slightly.

Movies for Bay State Employees.—The Bay State Street Railway is perfecting a series of moving picture exhibits to show to its motormen and conductors in connection with the company's "safety first" work. This demonstration exhibit is in charge of Harold W. Irwin, who is at the head of the instruction department of the company. One idea is to teach the motormen proper control of a car and to impress upon them the necessity of keeping brakes in proper condition. One series of pictures shows a "green" motorman driving a car down a steep grade. Another set of pictures shows the proper method for resuscitating a "shocked" man. Still another series of pictures shows the work of using the lifting jack which the state laws require every car to carry. It shows a victim under the car and the crew and passengers using the jack to lift the car so that he can be taken out. Replacing a derailed car on the tracks is illustrated by another set.

Increase in Fare in Barre.—The Barre & Montpelier Traction & Power Company, Montpelier, Vt., announced recently that it intended to put a 6-cent fare in operation in Barre on Aug. 12. Legal proceedings have already been begun on the part of Montpelier to test the franchise right of the company to charge a fare in excess of 5 cents within the city limits of Montpelier. Under a 6-cent rate for each city, or a 12-cent rate for a through ticket, the company divided the zones as follows: A Montpelier full fare passenger could ride on one fare as far as No. 1 switch, and a Barre passenger, bound for Montpelier, could ride as far as Intercity Park for 6 cents. Berlin passengers could ride in either direction for the 6-cent fare. It was announced that workmen's tickets would be sold in Barre at the rate of fifty rides for $1.75, an increase from 2½ to 3½ cents. It was intended to make the rate for school children eighty rides for $2. Reduced rate tickets, it was announced, would not be good on Sunday or holidays or in either direction for a part of through fare between Montpelier and Barre.

Increase in Wages in Memphis.—The Memphis (Tenn.) Street Railway has announced an increase in the wages of all motormen and conductors of 1 cent an hour, the increase applying to all such employees who have served more than six months. Men who have been with the company for six months will hereafter receive 18 cents an hour. One-year men will receive 21 cents; second year men 21 cents; third year men 22 cents; fourth year men 23 cents; fifth year men 24 cents; sixth year men 25 cents, and men whose service has extended to seven years or over will be paid 26 cents an hour. This increased scale does not affect the semi-annual bonus of 1 cent an hour for each hour's service which has been paid to conductors and motormen who during the six preceding months have not had an accident for which they were personally responsible. Announcement has also been made to all employees of the company of an allotment of stock in the American Cities Company, which controls the Memphis Street Railway and several other companies in the South. The stock is offered to employees at $63.50 per share, and subscriptions are voluntary.

Increase in Wages in Baltimore.—Motormen and conductors of the United Railways & Electric Company, Baltimore, Md., as well as other employees, have been informed of an increase in pay, which became effective on Aug. 11. The increase will total $200,000 a year, and it was said that the total of increases since 1912 has added $600,000 to the annual payroll. This is the third increase in wages since 1912. The schedule, providing for an increase of 2 cents an hour to each class of platform men is as follows: Class No. 1 will comprise men who have been in the service less than one year. They will be paid 22 cents an hour. Class No. 2 will comprise men who have been continuously in the service more than one year and less than two. They will be paid 23 cents an hour. Class No. 3 will comprise men who have been continuously in the service more than two years and less than three. They will be paid 24 cents an hour. Class No. 4 will comprise men who have been continuously in the service more than three years and less than five. They will be paid 25 cents an hour. Class No. 5 will comprise men who have been continuously in the service more than five years. They will be paid 26 cents an hour.

Chicago Turns to Electric Lines to Reduce Cost of Living.—In connection with the investigations now being carried on by the municipal, state and federal authorities to determine the cause for the unprecedented advance in the price of foodstuffs, the Chicago Municipal Markets Commission is planning an ordinance to effect relief. Among other things, this ordinance will provide for municipal stores in the poorer districts at which food will be sold at cost. It is also intended that the ordinance shall take up the question of transportation, and to this end the commission wants the assistance of the interurban electric railways. This is merely one of the results of the commission's investigation of the Chicago municipal market situation. An abstract of the commission's report in this connection was published in the ELECTRIC RAILWAY JOURNAL of May 2. As stated in that report, there are ten interurban roads which carry passengers and freight to the city limits, but are not permitted by ordinance to carry freight into the city. As a result of this it is necessary to handle farm products three or four times before they reach the consumer. It is now proposed that these lines be permitted by ordinance to haul freight in the city between 7 p. m. and 5 a. m. The operation of freight cars would not interfere with street railway traffic then, and it is believed that such a service would work materially to the advantage of consumers.

Personal Mention

Mr. William M. Coleman has been appointed general counsel of the Republic Railway & Light Company and the Central States Electric Corporation, New York, N. Y.

Mr. Ray Oswald, Delaware, Ohio, has been appointed assistant treasurer of the Columbus, Delaware & Marion Railway, Columbus, Ohio.

Mr. James W. Caldwell, Troy, N. Y., has been elected treasurer of the Columbus, Delaware & Marion Railway, Columbus, Ohio, to succeed Mr. Charles Gallinger.

Mr. C. V. Peel, formerly secretary of the Austin (Tex.) Electric Railway, now the Austin Street Railway, has been appointed chief clerk of the Carlisle Indian School at Carlisle, Pa. In 1910 Mr. Peel entered the service of the Indian Bureau at Washington as a clerk.

Mr. Frederic C. Howe, who was associated with the late Tom L. Johnson in his work in Cleveland and was president of a special commission from the United States which reported on municipal ownership in Great Britain, has been nominated by President Wilson for appointment as commissioner of immigration at Ellis Island, New York.

Mr. John L. Livers, general manager of the Charlottesville & Albermarle Railway, Charlottesville, Va., has also been elected president of the Goldsboro (N. C.) Street Railway and is in charge of the rehabilitation of the company's property, the operation of which was suspended for a time. New interests have taken over the Goldsboro property and the receiver has been discharged.

Mr. W. L. Henry, of Dorchester County, Maryland, has been appointed a member of the Maryland Public Service Commission, succeeding Mr. Philip D. Laird, former chairman of the board, who resigned. The new commissioner, who is a Democrat, will take office at once and will serve about eighteen months to complete Chairman Laird's unexpired term. Mr. Henry is a resident of Cambridge and is fifty years of age. Commissioner Alberg G. Towers has been designated as chairman of the commission.

OBITUARY

Maj. Joseph Pangborn, of the Baltimore & Ohio Railroad, is dead. Major Pangborn was a veteran of the Civil War and a journalist. He entered railroad work in 1880 and continued in active service until recently. He was well known as the author of "The World's Railway," in the preparation of which he spent seven years and traveled around the world in search of material.

Thomas A. Griffin, chairman of the board of directors of the Griffin Wheel Company, died on the steamer *Korea* en route from Yokohama, Japan, to Honolulu, Hawaiian Islands, on Aug. 12. He was completing a trip around the world, having started from New York on Jan. 13, 1914. Mr. Griffin was born in Rochester, N. Y., on Aug. 28, 1852, and has been in the car wheel manufacturing business continuously since 1868. In 1875 he went from Rochester, N. Y., to Detroit, Mich., where he engaged in car wheel manufacturing with his father, the late Thomas F. Griffin. In 1880 he came to Chicago and organized the Griffin & Wells Foundry Company. In 1886 this latter company was merged into the Griffin Wheel & Foundry Company, which later was changed to the Griffin Wheel Company. From the original single plant in Chicago this company has grown until now there are three Chicago foundries, as well as plants in Boston, Detroit, St. Paul, Denver, Kansas City, Tacoma and Los Angeles. Mr. Griffin, though he occupied the position of chairman of the board of directors of the Griffin Wheel Company, had not been active in its management for some years. He was a member of the Chicago Club, Chicago Athletic Association and South Shore Country Club, of Chicago; the Metropolitan Club, Racquet and Tennis Club and The Lambs, of New York; the Minnesota Club, of St. Paul; Maryland Club, of Baltimore; Denver Club, of Denver, and British Iron and Steel Institute. Two children survive him, George Francis Griffin, Chicago, now a vice-president of the company, and Mrs. Carl P. Dennett, Boston, Mass.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Monongahela Southern Traction Company, Brownsville, Pa.**—Chartered in Pennsylvania to construct an electric railway from California, Pa., to Brownsville, Pa. Capital stock, $108,000. Directors: C. L. Snowden, president, Brownsville; J. P. McKelvey, Pittsburgh; C. S. Story and F. B. Snowden, Brownsville; Linn V. Phillips, Uniontown.

***Salt Lake Light & Traction Company, Salt Lake City, Utah.**—Incorporated in Utah with a capital stock of $1,000,000. Incorporators: O. J. Salisbury, S. A. Whitney, C. W. Johnson, A. H. Parsons and J. B. Salisbury.

FRANCHISES

Clovis, Cal.—The Board of Trustees has authorized the offering of another street railway franchise through the town at public sale on Sept. 8.

Dixon, Cal.—The Sacramento Valley Electric Railway has received permission to enter Dixon on the southern limits under a one-year franchise granted by the city trustees.

Los Angeles, Cal.—The Pacific Electric Railway has received a franchise from the Council for a line from Sunset Boulevard on Maubert Avenue, almost to the Vermont Avenue entrance of Griffith Park, in Los Angeles.

Hillsboro, Ill.—The Southern Illinois Light & Power Company has received from the Village Board a renewal of the interurban franchise through Hillsboro.

Lafayette, Ind.—The Tippecanoe County Board of Commissioners has granted the Lafayette & Northwestern Traction Company the right to construct a line through the county. The company has also received franchises in Jasper, White and Newton Counties. (E. R. J., Aug. 1, '14.)

Hopkinsville, Ky.—A franchise, amended in some minor particulars at the suggestion of the Eastern capitalists who promise to build an electric railway in Hopkinsville, has been granted by the City Council and must now receive the consent of the mayor. [E. R. J., July 25, '14.]

Franklin, Mass.—The Dedham & Medway Street Railway has received a franchise from the Council on Main Street and Lincoln Street, in Franklin. [E. R. J., Aug. 8, '14.]

Springfield, Mass.—The Springfield Street Railway has asked the Council for a franchise for a change of location of its tracks on Main Street in Springfield.

Paterson, N. J.—The Public Service Railway, Newark, has applied for permission to construct a street railway in Broadway west of Mulberry Street, Paterson.

Buffalo, N. Y.—The International Railway has received permission from the Public Service Commission to extend its line through Tracy Street to connect the Grant and Elmwood lines in Buffalo.

Wilmington, N. C.—The Wilmington & Carolina Beach Railway, which plans to build an electric railway from Wrightsville to Carolina and Wilmington beaches, has received a franchise over certain streets in Wilmington, subject to the approval of the people at an election to be held Oct. 7. (E. R. J., Aug. 15, '14.)

Wilmington, N. C.—The Tidewater Power Company has asked the Council for a franchise to extend its lines in Wilmington.

Dayton, Ohio.—The Dayton Street Railway will ask the Council for a franchise for a relocation of its tracks on several streets in Dayton.

Milwaukee, Ore.—The amended franchise for right to construct an electric railway in Milwaukee, applied for by L. H. Campbell, will come up for consideration at a special meeting of the Council to be held this month. A twenty-five-year franchise is asked for. Work on the line must start within sixty days after the date of acceptance of franchise, and the lines must be in operation within eighteen months after the ordinance goes into effect. The company is required to pay the city of Milwaukee $200 annually. [E. R. J., May 16, '14.]

Danville, Va.—The Danville Traction & Power Company has received a franchise from the Council to extend its lines in the eastern section of Danville.

Everett, Wash.—The Everett Railway, Light & Water Company, a subsidiary of the Stone & Webster Corporation, will ask the Council for a franchise shortly to extend its line down Maple Street to First and west on First to the corner of Cedar Street.

***Seattle, Wash.**—A. P. Gillies, 444 Henry Building, Seattle, has applied to the Council for a franchise to run tunnels a total distance of 3 miles under city streets and to construct a doubletrack electric line to operate from Elliott Avenue and Virginia Street to Lake Union. Mr. Gillies represents the Bridle Belt Railroad & Navigation Company.

Snohomish, Wash.—An ordinance has been introduced in the Council granting a franchise to the Everett Railway, Light & Water Company to build a line from the Northern Pacific right-of-way to Cedar Street.

TRACK AND ROADWAY

Little Rock & Hot Springs Electric Railway, Little Rock, Ark.—The City Council has extended the time for beginning the construction of this company's line until Aug. 15, 1915, and the time for the completion until Aug. 15, 1918. The Arkansas Interurban Construction Company has the contract to build the line.

Benicia Land & Terminal Company, Benicia, Cal.—Engineers for the Benicia Land & Terminal Company have begun the surveying necessary before the company can make application for franchises for the proposed electric railway between Benicia and Vallejo. [E. R. J., July 18, '14.]

Montecito Railroad, Los Angeles, Cal.—The Railroad Commission of California has rendered a decision authorizing the Montecito Railroad to issue 50,000 shares of capital stock of the par value of $1 each. The proceeds from the sale of this stock are to be used by the company to build a street railroad 2.4 miles in length in Los Angeles.

San Francisco-Oakland Terminal Railways, Oakland, Cal.—Finishing touches are being put by the San Francisco-Oakland Terminal Railways upon the first unit of street railway extension and improvement undertaken by it in Richmond since the reorganization. Double-tracking on the main parts of the system, putting in heavier rails, repaving along its lines and other work are features of the corporation's activity in that city.

Waycross Street & Suburban Railway, Waycross, Ga.—It is understood that this company has completed plans for an extension from its carhouse on Johnson Avenue to Hebardville.

Galesburg Railway & Light Company, Galesburg, Ill.—This company is laying 6-in. 73-lb. rails on all streets where new pavements are ordered by the local board of improvements.

Waterloo, Cedar Falls & Northern Railroad, Waterloo, Ia.—This company has just completed laying the rails in its new 60-mile extension between Waterloo and Cedar Rapids, Ia. The work of ballasting is following closely the track laying outfit, being approximately 5 miles behind it. This will put the new line in operation six weeks ahead of the scheduled time. The electrical equipment has been planned so that this new 60-mile extension will be operated at 1200 volts. In all of the principal cities touched extensive freight and passenger facilities have been provided, and arrangements have been made with the Chicago & Northwestern Railroad for using its freight terminals at Cedar Rapids.

Kansas City, Kaw Valley & Western Railway, Bonner Springs, Kan.—Plans are being made to begin work soon on the extension from Bonner Springs to Lawrence, via the Union Pacific Railroad right-of-way.

Kentucky Central Electric Railway, Frankfort, Ky.—This company has decided to abandon the project to build the electric line to connect Louisville and Buffalo with a branch to Lincoln Farm and Glasgow. J. M. Richerson, Glasgow, president. [E. R. J., June 29, '12.]

Louisville & Interurban Railroad, Louisville, Ky.—Reports are current that a hotel is to be built at Fern Grove, Ind., on the Ohio River, several miles above Louisville. This would involve extension of the Prospect line of the Louisville & Interurban Company for a distance of about 5 miles, to a point on the river opposite the resort.

New Orleans Railway & Light Company, New Orleans, La.—An extension of the Claiborne Street line on St. Claude Avenue is proposed by the New Orleans Railway & Light Company.

Thibodaux, La.—Plans are under way for the organization of a company to be known as the Louisiana Railway, Light & Power Company, which proposes to construct a 56-mile electric railway from Lockport to Donaldsville, La. According to Walter Ohlmeyer, Plattenville, La., one of the promoters, the line will serve a densely-populated rural section and run through a level country. The promoters are now arranging with parties to finance the line. It is also the intention to sell light and power to the towns along the route. [E. R. J., Aug. 1, '14.]

Springfield (Mass.) Street Railway.—This company is asked to consider plans for an extension from Chestnut Street and Carew Street in Springfield, extending easterly through Carew Street to St. James Avenue, and St. James Boulevard, and thence to Page Boulevard to connect with the present electric railway on Page Boulevard.

Miller's River Street Railway, Miller's Falls, Mass.—No definite plans have yet been made when work will be begun on the construction of this line between Orange and Miller's Falls. D. P. Abercrombie, secretary. [E. R. J., Feb. 21, '14.]

St. Paul (Minn.) City Railway.—Work has been begun by this company on its Dale Street crosstown line in St. Paul.

Mississippi Electric Railway, Columbus, Miss.—Preliminary arrangements are being made by this company to build an electric railway from Memphis, Tenn., to Columbus, Miss., and eventually extend it into Alabama through Pickens County, with Aliceville as the terminus. Headquarters: Columbus, F. W. Crisby, Columbus, is interested. [E. R. J., March 28, '14.]

Meridian Light & Railway Company, Meridian, Miss.—This company has begun construction of an extension on Twenty-fourth Avenue to a point beyond Poplar Springs, 3½ miles from the center of the city.

***Kansas City, Mo.**—R. A. Long and associates are reported to be considering plans for the construction of an interurban railway between Kansas City, Lees Summit, Pleasant Hill and Harrisonville.

Missouri & Kansas City Interurban Railway, Kansas City, Mo.—The proposal to extend the lines of this company from Olathe to Ottawa has been revived.

St. Joseph Railway, Light, Heat & Power Company, St. Joseph, Mo.—An extension of the Prospect Avenue line from Prospect Avenue and Market Street to Third Street and Highland Avenue in St. Joseph is being considered by this company.

Lincoln (Neb.) Traction Company.—Plans are being made by this company to extend its line in Lincoln to Thirty-third Street.

Wilmington-Carolina Beach Railway, Wilmington, N. C.—The City Council has approved a petition and franchise authorizing the Wilmington-Carolina Beach Railway to occupy about 10 miles of streets with tracks and also to generate and sell electricity for light, heat and power. The franchises will be submitted to a vote of the people on Oct. 7. C. C. Chadbourn, Wilmington, president. [E. R. J., Aug. 15, '14.]

Columbus (Ohio) Railway, Light & Power Company.—This company on Aug. 11 filed its acceptance of the ordinance permitting a relocation of its track from Hosack Street to Barthman Avenue. The track will be relaid by the company in order to allow the interurban cars to take the grade at the Parsons Avenue viaduct with greater ease. The company has received permission to construct a double-track line on Park Street to be used for rerouting purposes while High Street is being improved.

Hocking-Sunday Creek Traction Company, Nelsonville, Ohio.—This company has received permission from the Public Utilities Commission to issue $300,000 of bonds to run twenty years and draw 6 per cent interest. The sum of $156,200 of the bonds is to be used in refunding present bonded indebtedness of the company and the remainder, $143,800, is to be used to construct a line from Athens to Chauncey, 5 miles.

Bristol (Tenn.) Traction Company.—This company has completed the conversion of the Holston Valley Railroad from steam to electric motive power, and has put it in operation as part of its electric system. The Holston Valley line is 11 miles long.

Bristol (Tenn.) Traction Company.—The extension to Big Creek has been placed in operation by this company.

Dallas, Tex.—A preliminary survey will be begun shortly by the Fred A. Jones Company, Dallas, for a proposed electric interurban railway from Dallas to Wichita Falls, about 100 miles. William Doran, Dallas, one of the promoters, states that the company has only taken up preliminary work on the projected line and it will not know whether the plan will be feasible until the engineer's report is made. [E. R. J., July 4, '14.]

Houston (Tex.) Electric Railway.—The 4-mile extension to Sunset Heights and Independence Heights has been placed in operation by this company.

***Palestine, Tex.**—W. H. Brashier, Corpus Christi, has made a formal proposition to the business league for the construction of a street railway in Palestine. Mr. Brashier proposes to advance $25,000 if the citizens will put up $40,000 and bond the company for the remainder, having the capital stock at $125,000.

SHOPS AND BUILDINGS

British Columbia Electric Railway, Vancouver, B. C.—This company has placed a contract with E. P. Harris & Company for the installation of an elevator in the carhouse at Fourteenth Avenue and Main Street, Vancouver.

New Paltz, Highland & Poughkeepsie Traction Company, New Paltz, N. Y.—Charles H. Higgins, New York, is preparing plans and specifications for a carhouse and offices of frame and sheet metal construction for the New Paltz, Highland & Poughkeepsie Traction Company at New Paltz.

Toledo, Bowling Green & Southern Traction Company, Toledo, Ohio.—This company has secured a permit to build an addition to its freight house on St. Clair Street, Toledo, to cost $12,000. The building will be of brick and provision will be made for the company's local offices.

Seattle (Wash.) Municipal Street Railway.—Bids are now being received by the Board of Public Works for the construction of a one-story carhouse for the Seattle Municipal Street Railway on the Lake Burien & Highland Park line. The carhouse will have corrugated iron roof and corrugated iron doors.

POWER HOUSES AND SUBSTATIONS

Riverside (N. J.) Traction Company.—This company has received permission from the Public Utility Commissioners to issue $51,000 of 5 per cent mortgage bonds for the erection of a new power plant at Burlington.

Knoxville Railway & Light Company, Knoxville, Tenn.—This company is spending about $300,000 for improvements in connection with underground wiring. A contract for the erection of transformer stations has been let to L. C. Powers, Knoxville.

Monongahela Valley Traction Company, Fairmount, W. Va.—This company is said to have awarded contracts for equipment for its power plant to be erected at Hutchinson, at a cost of about $300,000. The company's plant at Jayenne will be abandoned owing to acid in the waters of the West Fork River.

Fayette Traction Company, Fayetteville, W. Va.—Preparations are being made by this company for the construction of a power plant and other details in connection with the completion of its proposed electric railway between Fayette and Fayetteville, for which $50,000 in bonds were recently authorized. [E. R. J., May 2, '14.]

Manufactures and Supplies

ROLLING STOCK

Union Street Railway, New Bedford, Mass., is considering the purchase of two new cars.

Springfield (Ohio) Railway has ordered ten passenger cars from The J. G. Brill Company.

Richmond Light & Railroad Company, New York, N. Y., is in the market for thirty-two double-truck passenger cars.

Boston (Mass.) Elevated Railway is expecting to purchase thirty-seven center-entrance vestibules for the purpose of constructing articulated cars out of its closed cars.

Rio de Janeiro (Brazil) Tramways is not at present considering the purchase of new rolling stock, as reported in an item in the ELECTRIC RAILWAY JOURNAL of Aug. 1.

New York Municipal Railway, Brooklyn, N. Y., noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, 1914, as having been authorized to order 100 additional steel cars, has placed this order with the American Car & Foundry Company.

Aubany Southern Railroad, Rensselaer, N. Y., noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, as having been authorized to purchase one express car, has placed this order with the American Car & Foundry Company.

Illinois Traction System, Peoria, Ill., is constructing at its shops at Decatur, Ill., four large express cars to be used in hauling Adams express over the lines. These cars will be placed on the heavy runs so as to relieve the front end of the passenger cars where, as a general rule, the express is usually handled.

Springfield (Mass.) Street Railway, noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8 as having ordered ten city prepayment passenger cars from the Wason Manufacturing Company, has reported additional details for this equipment. The cars will be 43 ft. 4 in. over all with a 30-ft. body and 6-ft. platforms. Seating arrangements will be provided for forty-eight instead of thirty-six passengers, as with the cars now in service. There will be sixteen rattan side seats accommodating two passengers each, and four longitudinal end seating four passengers each. Straps will be provided only at the ends. The new cars will have arched ceilings, painted ivory white. The lighting system provides for a row of five 56-watt tungsten lamps in the center of the ceiling, with Holophane shades. One of these high-power lamps will be placed on each platform. The cars will be equipped with folding doors and steps. The Worcester (Mass.) Consolidated Street Railway, which recently ordered ten cars from the Osgood Bradley Car Company, has specified cars of a similar type.

TRADE NOTES

Poole Engineering & Machine Company, Baltimore, Md., has reorganized its engineering, foundry and machine business, with S. Proctor Brady as president.

Canadian General Electric Company, Ltd., Toronto, Ont., has appointed H. C. Cox, of Toronto, as a director of the company in place of his brother, the late E. W. Cox.

Automatic Ventilator Company, New York, N. Y., has received an order to equip with ventilators the fifty cars which were recently ordered by the Rhode Island Company from the Laconia Car Company.

C. W. Rhoades has been appointed manager of sales of the Daniels Safety Device Company, Chicago, Ill., manufacturer of the Bulldog self-locking nut. Mr. Rhoades was until recently assistant sales manager in the railway department of Valentine & Company, Chicago, Ill.

Heywood Brothers & Wakefield Company, Wakefield, Mass., announces the termination of the strike with its employees. The strike was declared off by the American Federation of Labor and the same working terms which had previously existed before the strike have been accepted.

Terry Steam Turbine Company, Hartford, Conn., has appointed Fidanque Brothers & Sons of New York and Panama, with main office at 15 Whitehall Street, New York, as its representatives for the Republic of Panama and the Canal Zone. The former company has moved its Cleveland office, in charge of L. G. Finlay, from 710 New England Building to 503 Union Building.

A. L. Whipple, New York, N. Y., recently with the A. L. Whipple Company, has taken the exclusive agency for railroads and electric railways for Oakite. This is the name of a cleansing compound, which has been manufactured for the past six years by the Oakley Chemical Company, New York, for general purposes, but not heretofore offered especially to the railway trade. The material is intended for use in cleaning cars at terminals, and can be used on car bodies without injury to the paint or varnish, for cleaning rattan seats or metal parts, washing floors, etc. In a stronger solution it can be used for cleaning paint pails and varnish cups and in the "potash" tank of the armature room. The interruption to the supply of potash from abroad owing to the war makes this use of especial interest. Oakite is a compound of salts and has an alkaline reaction. The manufacturers direct special attention to the fact that this product replaces lye and potash without any detrimental effect whatsoever and without any danger. As it contains no grease or oil, there is no soap film remaining on cleaned surfaces, and as it is not an alkali or acid, there is no crawling after revarnishing and nothing left in pits or pores to eat through plating lacquer or metal, and no fumes to injure the eyes and lungs where it has been used in preparatory cleaning. The manufacturers have prepared special directions for the use of this cleanser for its various purposes.

Westinghouse Air Brake Company, Pittsburgh, Pa., some time ago offered the sum of $2000 in prizes, as announced in several advertisements published in various technical papers at the time. The company stated that it would pay this sum of money for the six best stories submitted, under certain conditions, dealing with the experience and practical knowledge of railroad employees regarding any striking performance of the air brake manufactured by this company. The history of braking railroad trains is full and complete in dramatic but unwritten narrative, and the company believes that by offering this incentive a vast amount of this material will be brought to light. The conditions stated that the story must be written either from the practical experience or the personal observation of the writer, or from information obtained first hand from railroad men who actually knew the facts related. The contest closed Aug. 1, 1914, and the committee of judges composed of the following men is now engaged in judging the entries: W. E. Symons, consulting mechanical engineer, Chicago; Willard Smith, Editor *Railway Review*, Chicago; and R. V. Wright, Managing Editor of the *Railway Age Gazette*, New York City. A great deal of interest was displayed in the contest, and the large number of stories that were submitted means that several weeks will elapse before the judges will be able to announce the winners of the prizes.

ADVERTISING LITERATURE

Western Electric Company, New York, N. Y., has recently issued two catalogs, one on magneto telephones, switchboards and supplies, another on telephone cords.

American Electrical Works, Phillipsdale, R. I., has issued a price list of its copper, weather proof, galvanized iron, magnet and other kinds of wire, cables and lamp cord.

H. A. Strauss Data-Card Service, Chicago, Ill., has issued, among its recent additional specimen engineering data cards, a card giving various unit operating data of a typical modern size d. c. electric locomotive for interurban operation.

Schutte & Koerting Company, Philadelphia, Pa., has issued Catalog 5, Section AB, which describes and illustrated its multi-jet condenser. The only moving part required for the operation of this condenser is a centrifugal pump which supplies the water to the condenser by a pressure of 9 lb.

St. Louis Steel Foundry Company, St. Louis, Mo., has just issued a new catalog of solid manganese steel track work for steam and electric roads. In a foreword it is stated that this company specializes in solid cast manganese steel track work, and that the work illustrated in the catalog is all machine-ground to templet and dimension, and is absolutely interchangeable. Among other things the catalog illustrates and describes the Steedman patent undercut tongue switch, grooved girder solid manganese crossings of various angles and designs, this company's new method of stiffening the intersecting flangeway bearing in solid manganese crossings and its method of reinforcing and protecting plain end and joint ends of solid manganese special work. Various types of solid manganese inserts and commercial castings are also illustrated and described.

American Rolling Mill Company, Middletown, Ohio, has issued a catalog entitled "Defeating Rust," which describes the various uses of its Armco iron, which in the electric railway industry includes bridge flooring, cattle guards, coal chutes, corrugated culverts, electrical transformer tanks, fence posts, hot water heaters and pipes, metal cars, metal window frames, smokestacks, skylights, terne plates, third rails, ventilators and wire fencing. The catalog outlines the special attention given by the chemical laboratory of this manufacturer towards securing a pure iron as possible in order that it may have a maximum rust resisting power. The catalog also contains a large number of testimonial letters from users of this iron and shows illustrations of culverts installed by steam and electric railways. Another catalog entitled "Iron Roofs that Resist Rust" describes various kinds of iron roofing and siding materials manufactured by this company. A third catalog has also been recently issued and is entitled "A Journey to Armco Farm."

Prest-O-Lite Company, Inc., Indianapolis, Ind., has issued two folders on the subject of oxy-acetylene welding. One folder describes the special features of the Prest-O-Lite welding. This welding outfit is light and portable. The use of acetylene dissolved in large cylinders eliminates the waste of gas, characteristic of the acetylene generator. With accurate regulating devices perfect steadiness of the flame is insured. Explosion from fire is prevented by the melting of safety plugs in both ends of the cylinder which allows the acetylene to escape and burn harmlessly at the openings. The outfit requires no generator to charge or clean out, and has no other details which require attention. The second folder describes the advantages of this process in welding and cutting apparatus in electric railways, shops, yards and tracks. Rail bonding by this process is discussed with the aid of illustrations. The special advantages claimed by the use of this method are economy due to rapidity of work, small gang and low cost of tools and supplies, non-interference with traffic, and low cost and portability of the apparatus used in bonding. Other illustrations show the making of repairs in various parts of car equipment, such as a broken gear tooth, main shaft bolt cutter, keyway in armature shaft, motor nose, cracked gear case and motor compressor case. Views also show the outfit used as a cutter of sections of iron and steel for the scrap yard.

NEW PUBLICATION

The Railway Library. Compiled and edited by Slason Thompson, director of Bureau of Railway News and Statistics. R. R. Donnelley & Sons Company, Chicago. Cloth, 5½ x 8¼ in., 269 pages, illustrated, 50 cents.

This volume, which is the fifth annual issue of The Railway Library, follows previous custom in bringing together the most noteworthy papers presented during 1913 on a wide variety of railroad subjects. In general the topics are devoted to the wider aspects of railroad work, such as rates, wages, capitalization and government ownership. Some of the articles of most interest to electric railway men are as follows: "Certain Considerations in Rate Making," by Balthasar S. Meyer; "Apportionment of Expenses to Suburban Traffic of the Southern Pacific Company," by T. W. Durbrow; "The State and the Railways," by "The Spectator"; "Government Ownership of Railways," by Samuel O. Dunn; "Workmen's Compensation," by Frank B. White; "Valuation of Railroads," by Charles A. Prouty, and "Government Regulation of Railways," by William H. Herrin. Several of these papers have previously been abstracted in the ELECTRIC RAILWAY JOURNAL. The last 132 pages of the book are devoted to statistics of American railways for the year ended Dec. 30, 1913. There are also presented a chapter giving statistics of principal foreign railways and a table of contents for the previous four issues of The Railway Library.

Electric Railway Journal

Published by the McGraw Publishing Company, Inc.
Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY, AUGUST 29, 1914 No. 9

WHAT DID IT COST?

Last week we published a brief note regarding an attempt of the auditor of an electric road in Maryland to impress upon employees of the company the value of the small supplies which they handle in every-day work. Instead of the usual financial valuation he ingeniously used other units selected to bring the matter closer home. The notion that a lantern is the equivalent to the transportation of a passenger 37½ miles involves a stimulating transformation of ideas. It is extremely difficult for one individual to feel a sense of responsibility for the property of another, even if the other is his own employer, but this is more from thoughtlessness than intent. There is hope of economy, therefore, in every device designed to call attention to the facts. While this is true in regard to material things, it is even more so in connection with the use of time. An employee who would not deliberately throw new fuse plugs at the frogs in the pond near the car-house might unwittingly waste an equivalent value in time in "visiting" or "soldiering." He would not do this if he could "see" the time in the form of a tangible equivalent.

FUTILITY OF HEAVY SIDE SHEATHING

The communication by C. J. McPherson, published elsewhere in this issue, is a most valuable contribution to the many and varied arguments which seem, unfortunately, to be necessary in the process of evolution through which electric railway cars are now passing and during which it is to be hoped that the old-style, house-on-a-flat-car design will be replaced by the all-steel, side-truss type of construction. The basis upon which our contributor's conclusions rest is original but simple, an analysis having been made of stresses and weights (which need only to be considered comparatively) involved by a single standard type of car-side framing which is variously assumed to be constructed with and without sheathing and with and without a top plate. The results, as submitted, indicate forcibly that heavy side sheathing has only a questionable supporting value. With the introduction of a top plate, or where the whole side of the car is designed to act as a truss, the author shows the use of side sheathing to be quite as unnecessary as are facts in a war bulletin. The sheathing may be actually removed complete without an appreciable loss in strength. With the side-girder type of design, where the strains from the load extend only between the belt rail and sill, he shows that when the side sheet is removed there is an addition of only 38 per cent to the stress as against a reduction of 22 per cent in the beam weight. Following out Mr. McPherson's idea it may be calculated that if the strength is maintained by adding metal to the belt rail and sill, and if 1/16-in. sheathing is used as a gusset plate only, the beam weight will actually be reduced some 2 lb. per running foot. This illuminating exposition is something for designers to think over seriously.

SAVING UNDER GOVERNMENT OWNERSHIP

Considerable attention has been directed toward articles recently published by the *Saturday Evening Post* on the subject of government ownership of steam railroads. Drawing from a wide source of anti-railroad publicists, ex-Governor Stubbs of Kentucky started the program by producing a scarecrow that was calculated to frighten the most ardent believer in the private operation of public utilities. In a subsequent article, however, Edward P. Ripley, president of the Atchison, Topeka & Santa Fé Railway, easily disposed of most of the statements made by Mr. Stubbs. Since contributing this general refutation, Mr. Ripley has taken up more in detail the question of the savings that would result from government ownership of railways on account of the use of government credit. Being in doubt as to the accuracy of a statement by Clifford Thorne that the government would save $400,000,000 by financing the railroads on a 3 per cent basis, Mr. Ripley wrote to Sir George Paish, editor of the London *Statist*, who is well known all over the world as an authority on financial matters. In reply this expert stated that one could not possibly calculate a greater profit from immediate ownership than about $60,000,000 per annum on the common stock. Moreover, there could be no immediate saving of interest from government purchase as regards the funded debt, although a barely possible refunding at the maturity of the existing bonds might save $70,000,000 per annum. That such a saving as this is incomparably small when placed against the inevitable extravagance, waste and loss which results from government ownership, is a fact upon which we do not need here to dwell. The chief point to be noticed is the difference between the computations of amateur railway economists and those of a man thoroughly understanding railway finance. American newspapers have in recent years been surfeited with figures and articles written by government ownership advocates with a maximum of assurance and a minimum of information. A few pertinent facts from the real authorities in the field are often sufficient to overthrow the innumerable statements bandied about by such writers.

THE HYBRID STEEL-UNDERFRAME CAR

A recent statement on steel passenger cars in service on the steam railroads of the United States includes figures to show that, at the present time, there are in use approximately half as many cars with steel underframes as there are of all-steel construction. The steel-underframe cars are classed, by indirection, as steel cars, although wherein this assumption is warranted is by no means clear. Certainly the steel underframe, as a step in the evolution of the all-steel car, has served its purpose in full by this time, and it is obvious that it should diminish in comparative numbers on both the steam and electric railways at a rapidly accelerating rate.

This belief is supported by the figures given for past years by the steam railroads. In 1908 the all-steel passenger cars in service constituted 48 per cent of the combined number of steel and steel-underframe cars. In 1913 the number of all-steel cars had increased enough to change the ratio to 68 per cent and 32 per cent. On the basis of annual production the all-steel cars constructed during the year 1909 numbered 53.5 per cent, the steel-underframe cars constituting 46.5 per cent. For the year 1912 the corresponding figures were approximately 77 per cent and 23 per cent. The estimated figures for 1914 are 87 per cent for all-steel and 13 per cent for steel underframes, even though the latter figure includes the old wooden cars that were reconstructed with steel sills. Unfortunately, similar statistics are not available for the electric railway industry, but judging in general by the reports of the newly built cars the steel underframe is losing much less ground on electric railways than it is on the steam lines.

By steel underframe is meant, of course, a construction wherein no steel extends above the floor line. The so-called "side-girder design," now generally termed semi-steel, in which the side sheathing is made of steel plate that extends as high as the window sills is not, therefore, included, the obvious reason being that it escapes the inherently defective principle of carrying load on shallow beams which is involved by the true steel-underframe construction. This limitation of depth of beam is, of course, the most serious handicap that can be imposed upon any structure that carries weight, and it is no credit to the electric railway industry that the deleterious influence of this class of car design is not being grasped more promptly than is indicated by recent records.

That, of all the steps in the evolution from wood to steel as a material for car construction, the steel-underframe design for street railway cars should remain, even in its present moribund condition, is an absurdity. Foregoing all of the advantages of the girder or truss design that the use of steel makes possible, it retains only the feature of greater collision strength over wood, and in city service this advantage is worth just about as much as an umbrella for a school of fish. On the other hand, the steel underframe perpetuates the necessity for car repairmen working with steel, this being the most frequently quoted objection to the all-steel car, which may be purely psychological but is none the less difficult to overcome. At best, it is a hybrid construction with which the electric railways can well afford to dispense.

THE COMPETITION OF THE AUTOMOBILE

Our English tramway brethren have long been concerned at the inroads of the motor bus. American electric railway operators have not had to contend with this self-propelled vehicle but in many cities have had to face the competition of the private automobile. We realize that this competition is usually considered slight. But we do not know of any city except Denver where a serious attempt has been made to learn its actual extent. Of course, if only the owner rode to business the influence of the automobile on the trolley receipts would be small. But in a city of moderate size where the owner in a spirit of generosity and hospitality invites his next-door neighbor to take a seat in his car and extends this invitation as well to his other friends until the car is full, the total effect of a large number of cars is considerable. This truth is brought out with startling clearness by the traffic figures presented in this issue by Roger W. Toll, chief engineer Denver Tramways. The investigation conducted under Mr. Toll's supervision showed that on a typical weekday, passenger automobiles alone carried 8.2 per cent of all the traffic going by certain points in the business district. Furthermore, motorcycles and bicycles carried 6.4 per cent, horse-drawn vehicles, 1.3 per cent, and pedestrians constituted 29.2 per cent. This leaves 54.9 per cent to the street railway.

This figure is a lower proportion of the total travel than one would expect in most cities of greater size or even in those of equal size. In the large Eastern cities, for example, the bicycle and motorcycle are practically unknown for business uses; furthermore, in large cities the distance from the residential to the business district is too great for walking by so large a percentage as that found in Denver. But even if the influence of the passenger automobile alone is considered, Mr. Toll finds that its business in possible 5-cent fares is equivalent to $437,372.20 a year —a very tidy sum to add to the gross earnings of any company.

It is likely that prosperous Denver, with its wide, level streets and non-congested residential districts, has more than the usual number of automobiles. Still the time is not far away when many other cities may have the same or an even greater percentage of automobile traffic. When machines can be bought for only $440 each, the only factors that seem capable of impeding their extension to a point that would seriously impair street railway earnings are garage rentals, street spacing for safe travel and the rising price of fuel.

The inroads of the automobile are really more serious to the interurban electric railway than to the city railway. Much interurban travel is half business and half social, because so many people combine shopping and pleasure when they go, say once a week, from the country to the local metropolis. Many trips of this character are now made by automobile, with two or three neighbors as guests. Farmers who raise garden truck are also tempted to use the automobile when it can be used to convey their produce as well as themselves. From this angle it is clear that the interurbans can be hurt appreciably if they do not make it clear to prospective patrons that the cost of automobile trips is greater, while the speed, safety and convenience of such machines are less, than with the modern interurban car.

IMPENDING COMMERCIAL WARFARE

The present colossal struggle in Europe has naturally dislocated every phase of commercial life in the warring countries, but America cannot afford to accept the present situation with simply a vociferous welcome of increased commercial activities heretofore restricted by foreign competition. To be sure, the people of the United States as a whole have no desire to make capital out of the misfortunes of other peoples, but there may be a few effervescent spirits who will do well to look upon the present commercial opportunity as a chance for performing a real world service instead of merely conquering foreign markets.

At present the German overseas trade is virtually obliterated; the home of Belgian manufacturers is bathed in blood; English electric railway exports are comparatively small—all of which conditions make an unprecedented opening for us in the trade of South America and the Far East. Appreciation of the European catastrophe that has made this possible can be shown only through taking advantage of the present opportunity without unseemly precipitation and through endeavoring to afford South American countries as good, if not better, service than they have formerly received from our competitors.

To attain the above result, we must realize fully the difficulties confronting us, as pointed out in interviews with W. J. Clark and G. H. Charls, published elsewhere in this issue. It must be remembered that the cessation of European exports also means the cutting off of the great European customers for South American imports, and that the resulting South American trade restriction must be helped by our bankers and capitalists. South American sales requirements and conditions must also be studied and exactly met. Furthermore, it may be wise to note that English electrical manufacturers are hailing the opportunity for securing German trade in South America, and that some competition from this source will persist even in the face of danger. If these problems are properly solved by our manufacturers, there will come a boom to this country that will probably be permanent, but at the same time our friendly relations as a nation with all the European countries will be conserved. The ultimate result will probably be a more even division in the world's trade than has heretofore existed.

PERMANENT TRACK A FALLACY

Several articles and communications in recent issues of this paper have drawn attention to the lack of appreciation on the part of some companies of the importance of first-class maintenance of track. It appears that many street railway managers take the term "permanent track construction" literally and, failing to take the "stitch in time," find that the term is not only a fallacy but that the so-called permanent type of track construction lasts but little longer than its predecessor. If managers and engineers expect to profit by the increased life obtainable from the permanent types of track construction they must give constant attention to its maintenance.

Probably before any other defects which develop under traffic are in evidence, inequalities and inaccuracies in track construction will show themselves. After these have been corrected, the points subject to severest wear under traffic present themselves. Usually these occur in track special work or at the joints. In either case they generally take the form of cupping, and grinding or welding should immediately be prescribed. If this is done promptly, the defect will not be reflected in the substructure where the cost of repair is many times that of merely removing the cups on the surface at the proper time. Following the cupping at joints, many complications arise which ultimately destroy the entire structure, making a complete renewal necessary. In other words, the price of neglectful maintenance is high cost of operation. This is reflected not only in the future maintenance of the tracks but in the maintenance and in practically every phase of car operation.

No track structure is permanent, and it is foolish for anyone to consider that its maintenance may be forgotten even for the shortest period of time. The secret of true economy in the subject we are considering is unceasing vigilance followed by prompt repairs. When this vigilance is present but is accompanied by inefficient repair methods, or the repairs are made by incompetent men, the life of the structure is increased but the maximum is not obtained. The track is an engineering structure, and engineering intelligence must be put into it. As a rule the work of maintenance in the power station and in the repair shops is so concentrated that the engineer or master mechanic in charge can personally supervise the more difficult repairs. With the track department the case is entirely different—the work covers a wide area and much of the supervision must be left to the section foreman, who in most instances is nothing more than a first-class laborer.

If the same amount of intelligence and money was expended in maintaining a track structure in proportion to its cost as is expended in maintaining rolling stock and power station equipment, we firmly believe that the cost of track maintenance would be much lower than it is to-day, and undoubtedly the life of the structure would be greatly increased. Simply because a failure in either the power station or cars stops income is no economic reason for slighting the most expensive portion of the composite structure.

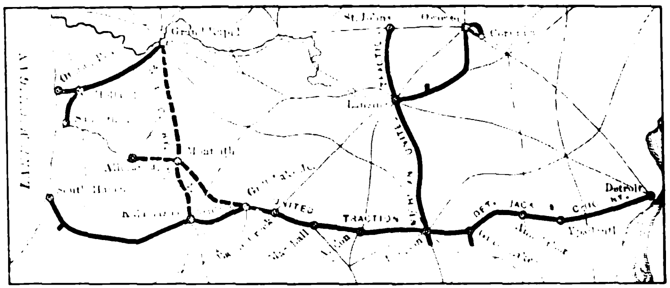
Third-Rail 2400-Volt Construction on the New Michigan & Chicago Railway

This High-Speed Line Connecting Kalamazoo and Grand Rapids Will Be the First Electric Railway in the World to Use a 2400-Volt Third-Rail—The Line Will Be Placed in Operation Next Autumn

Another long stride in the advance of direct-current voltages for third-rail operation will be taken when the new Michigan & Chicago Railway's 2400-volt line is completed. When ready for operation this line will include 91 miles of single track in southern Michigan, connecting Kalamazoo and Grand Rapids, and also Allegan and Battle Creek. That portion of the line between Kalamazoo and Grand Rapids, 49 miles in length, is being newly constructed throughout. The line between Allegan and Battle Creek, 42 miles long, is an old steam road purchased from the Michigan Central Railroad and it is now being electrified for 2400-volt, third-rail operation.

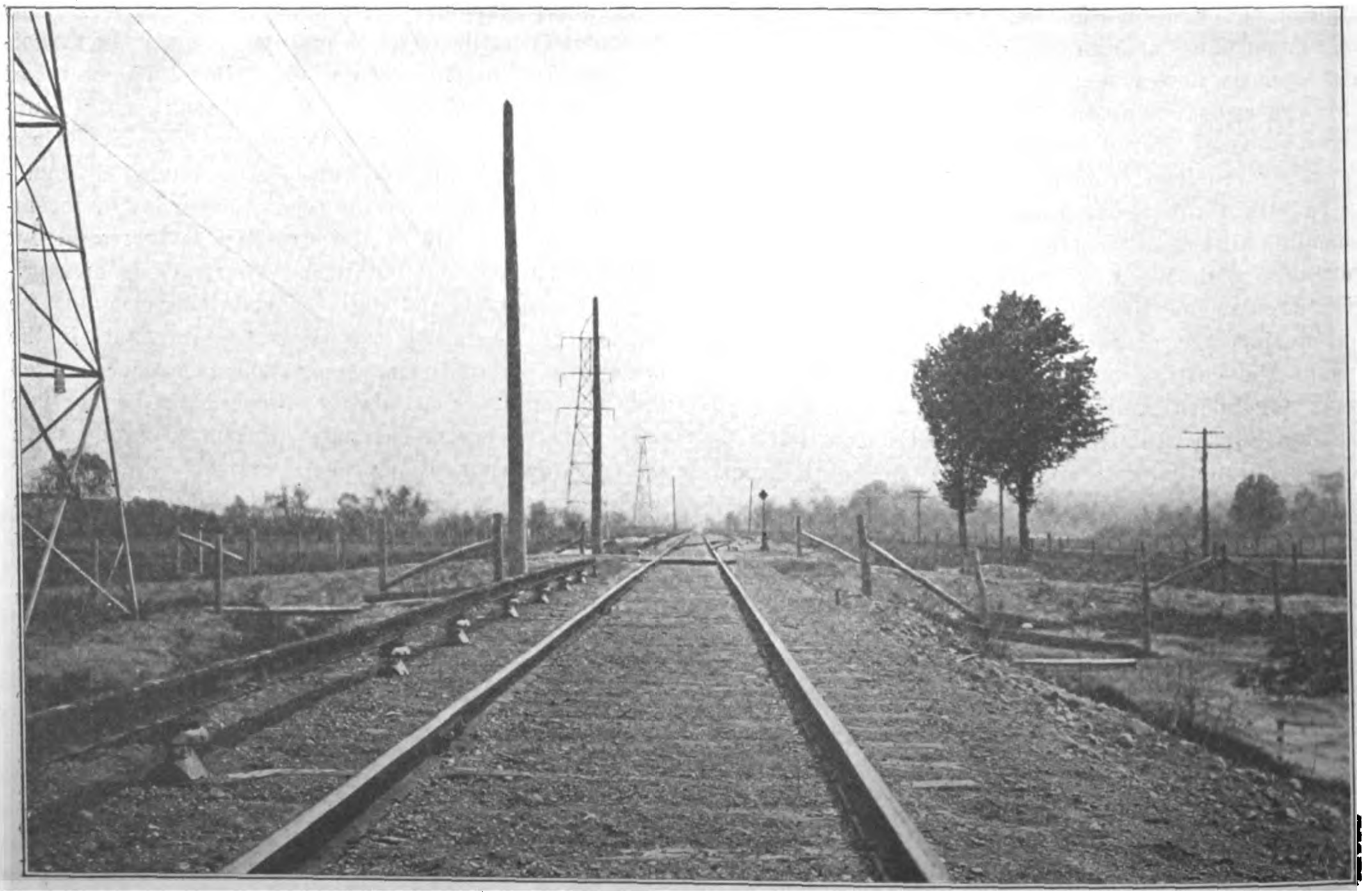
Standards adopted for the construction of this new line provide for high speed with 3 deg. maximum curves and 1 per cent maximum grades. All track, including main line and sidings, is being laid with 80-lb. A. S. C. E. rail on 6-in. x 8-in. x 8-ft. cedar ties, spaced twenty to a 33-ft. rail. Every sixth tie is 10 ft. long, the additional length being provided to furnish support for the third-rail. All sidings are being made double end with No. 12 turnouts having 90-ft. leads, and each siding provides 600 ft. of track in the clear. Both side tracks and main tracks are laid on from 6 to 8 in. of gravel ballast distributed in sufficient quantities to provide a liberal shoulder. Track bonding includes compressed terminal cross-bonds and exposed, Type J, Ohio Brass bonds at all joints.

In order to adhere to the track and roadway standards the grading quantities per mile averaged approximately 20,000 cu. yd., making the total for the new 49-mile line amount to about 1,000,000 yd. The subgrade standards provided for a 100-ft. private right-of-way, and a 16-ft. roadbed in cuts and fills with ample provision for drainage in the former. All waterways under the subgrade are provided with permanent structures. Where reinforced concrete pipe would not supply a sufficiently large opening, reinforced concrete, flat-top arches were constructed. In a few instances the spans were too long for this design and at these points through girders with ballast decks were installed.



Electric Ry Journal

MICHIGAN & CHICAGO RAILWAY—MAP OF THE SYSTEM



MICHIGAN & CHICAGO RAILWAY—VIEW SHOWING THIRD-RAIL AND TRACK CONSTRUCTION

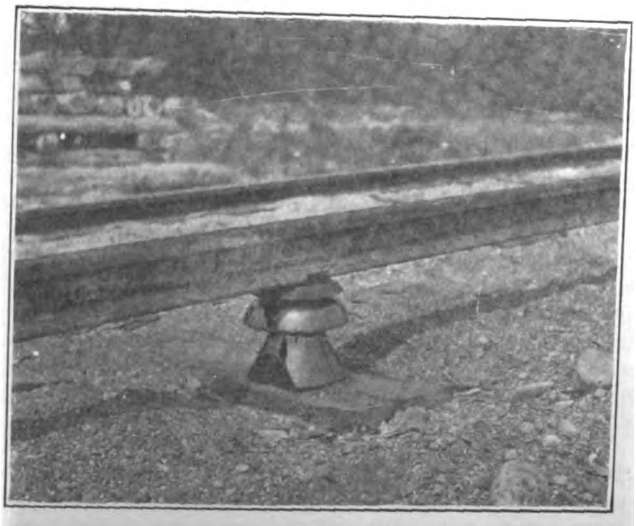
At the present time two bridges are under construction, one over the Kalamazoo River at Kalamazoo, and the other over the Grand River at Grand Rapids. Both of these are important structures, as they provide direct entrance to the north and south terminals of the new line. The bridge at Grand Rapids is a permanent one that rests on concrete piers and abutments. The one at Kalamazoo is a timber trestle with one set of through girders. A temporary structure was provided at the latter point in order to permit a more thorough study of the waterway requirements before a permanent bridge is provided.

2400-VOLT, THIRD-RAIL DETAILS

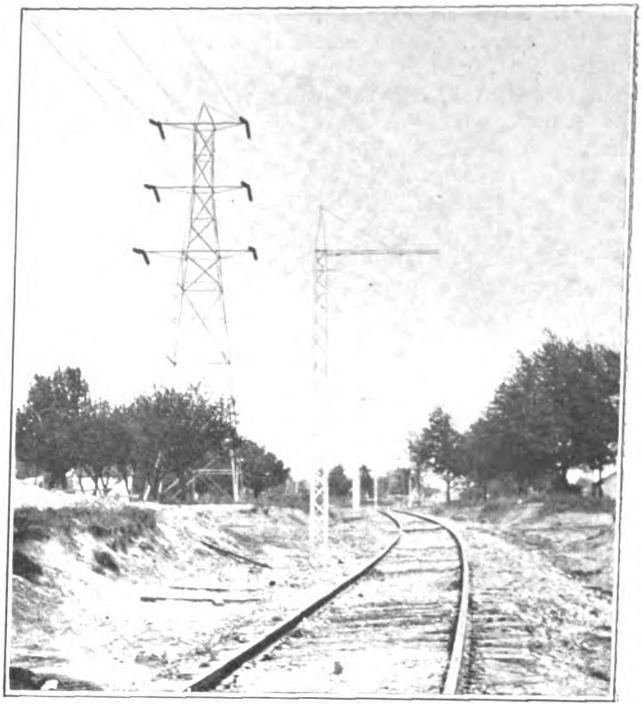
Undoubtedly the most interesting part of the construction of this new line is found in the manner of supporting and insulating the 2400-volt third-rail. Practically all of the third-rail is now in place, and tests are now being conducted to determine the best method of providing an insulated guard for it. As shown in the accompanying illustration the third-rail is installed on special insulators, which are 8½ in. high and are provided with a single petticoat 9⅓ in. in diameter. After the long ties have been accurately adzed to insure a uniform third-rail surface, a small rectangular casting is fastened to the tie with a lag screw. A pocket in the base of the third-rail insulator fits snugly over this base casting. A similar pocket in the top of the insulator takes a malleable iron saddle casting provided with lugs which exactly span the third-rail base. Both the insulator and the third-rail are held in position by their own weight, and the rail is permitted to move freely in accordance with the effects of expansion and contraction.

Prior to adopting the third-rail clearance a careful study was made of a number of Eastern steam-road electrifications that use third-rails in order to determine what clearance would be ample for all classes of equipment. As a result of this study the third-rail was placed at a horizontal distance of 32 in. from the adjacent track rail and 8½ in. above the track-rail surface. This clearance is believed to be ample for any steam-road equipment on tangent track, but at turnouts it was found necessary to depress the third-rail approximately to the same elevation as that of the track rail to insure clearance as a car passes over the switch points into the lead curve. All third-rails are stub-ended at crossings, and poles are set each side to support an overhead contact wire.

Through the cities and villages where the line leaves the 100-ft. private right-of-way, or where it is necessary to provide team tracks and station facilities, the propulsion current is carried on overhead trolley wires. At these locations galvanized structural poles with mast-arms are provided. The poles are 35 ft. long and are set with 18 in. of concrete at the bottom of the hole and 18 in. at the top. The sections of overhead trolley which are carried on the mast-arm construction are dead-ended by connecting the trolley ends to a pair of structural-steel galvanized poles, one set each side of the track. A view of this class of construction is shown in one of the illustrations.



MICHIGAN & CHICAGO RAILWAY—VIEW OF THIRD-RAIL CONSTRUCTION



MICHIGAN & CHICAGO RAILWAY—VIEW SHOWING OVERHEAD TROLLEY CONSTRUCTION THROUGH CITIES

As the third-rail clearance was unusually wide the use of a specially designed third-rail shoe was required to provide for operation through public streets. Accordingly, the shoe was arranged to operate with a pneumatic folding mechanism under the control of the motorman. Since practically the entire line is on private right-of-way, even well into the cities of Kalamazoo, Battle Creek and Grand Rapids, these third-rail shoes need be in the folded position only during the short intervals when a car is operating over the streets at these terminals.

SUPPLY OF ENERGY

According to present plans the whole line will be fed from Kalamazoo, Battle Creek and Grand Rapids at 2400 volts d.c., and no additional feeder other than the 80-lb., A. S. C. E., low-carbon third-rail will be employed. In case energy supplied from these three points is insufficient, 42,000-volt and 70,000-volt a.c. transmission lines that are already installed on steel towers along the private right-of-way may be tapped to supply energy to a substation at some intermediate point. This transmission line forms a part of the network of lighting and power lines of the Commonwealth Power & Light Company, owned and operated by the same holding company as the one which owns the new railway line.

PRESENT STATUS OF WORK

The work completed up to June 1 includes all the track and roadway except that portion in the immediate vicinity of the cities of Kalamazoo and Grand

Rapids. All third-rail is now installed but is awaiting the selection and installation of the protecting guard. Entrance to Kalamazoo and to Grand Rapids is arranged for, but the work was delayed both by the franchise negotiations and the construction of the two bridges mentioned.

The electrification of the steam road between Allegan and Battle Creek has been started. Third-rail ties are being placed and the overhead construction through the cities and villages is well under way. Three new telephone circuits will be provided on both divisions of the line. One will be used for train dispatching, one for commercial purposes and the third for power dispatching. These lines are being constructed on separate wooden poles. The overhead transmission power line is complete, but will not be put in service until the railway is ready for operation.

When the Michigan & Chicago Railway is completed it will form a part of the Michigan Railway Company's system, which is operated by the officers of the Michigan United Traction Company. This system includes the Michigan United Traction Company that operates a 1200-600-volt d.c. overhead and third-rail line; the Grand Rapids, Holland & Chicago Railway, a 1200-600-volt overhead line; the Saginaw-Flint Railway, a 1200-600-volt overhead and third-rail line, and the new Michigan & Chicago Railway, which will be a 2400-1200-volt third-rail line. In total length this system comprises approximately 470 miles of single track, practically all of which will be operated at 1200 volts on private right-of-way, excepting the Michigan & Chicago Railway, which will start at 1200 volts and later be raised to 2400 volts.

Responsibility for Pavement Repair Along Car Tracks in Chicago

In an article by P. E. Green, consulting engineer of Chicago, printed in the *Engineering Record*, the question of pavement deterioration along street railway tracks in Chicago is discussed. An abstract follows:

One of the most perplexing problems in modern city pavement is the maintenance of a first-class pavement along street railway tracks. In practically all cities this trouble is encountered. The city of Chicago has lately won an exceedingly important case in litigation on this point. The decision means hundreds of thousands of dollars to the city and to various contractors. It will undoubtedly be appealed and hence will not be finally decided for two or three years.

In order that the following discussion may be clear, the "brow pavement" is defined as that part of the paving area within a couple of feet and outside of the street railway tracks. The "quarter point" or "quarter" is the point midway between the outer rail and the curb.

Lincoln Avenue, where this question arose, is one of the principal secondary business streets of the North Side of Chicago. It is a diagonal street and accommodates a heavy traffic, both vehicular and street railway. It is paved with creosoted-wood blocks on a sand bed 1 in. in thickness and a 6-in. concrete foundation. The pavement was constructed in three sections—the first mile in 1907, the second mile in 1908 and the third mile in 1909. The space between the rails and tracks is paved with granite block for the first two miles and with wood block in the third. The creosoted-wood block pavement is laid in rows of approximately 45 deg. to within 4 in. of the rail. Most of the brow has a single longitudinal block laid parallel with the rail. On the west side of the first mile, however, the diagonal rows extend to the edge of the rail.

The railway construction is what is known as "Type 3," as adopted by the Board of Supervising Engineers, Chicago Traction. This type of track consists of a lower course of 8 in. of crushed stone upon which the ties and rails are laid. The ties and bases of the rails are covered and surrounded by 8 in. of concrete. On the top of the concrete is spread the sand bed, and the pavement is laid on this. In the first mile mentioned, in addition to this crushed stone, crushed cobbles were placed in the bottom of the track trench and the whole was thoroughly rolled with an Iroquois 10-ton roller. Particular attention is called to this type of construction, as its ability to stand up under the traffic was a question of the problem discussed in the following paragraphs. The rails themselves were of the 129-lb. Chicago section.

In longitudinal profile the street is exceedingly flat, there being only about 3 ft. difference in elevation in 3 miles. The roadway of Lincoln Avenue is 42 ft. wide from curb to curb. Since the railway right-of-way is 16 ft. wide, the pavement is approximately 13 ft. wide on each side of the railway right-of-way.

TRAFFIC CENSUS

Traffic is heavier in the first mile, especially as regards the railway traffic, than in the second or third mile. This is because Lincoln Avenue is known as a through-route street, and at the end of the first mile some of the cars turn off the avenue. A census of the traffic taken between the hours of 7.30 a. m. and 10 p. m. is given in the table.

CENSUS OF TRAFFIC BETWEEN 7.30 A. M. AND 10 P. M.

First mile	Street cars 1041,	Vehicular traffic 1500
Second mile	Street cars 746,	Vehicular traffic 1814
Third mile	Street cars 457,	Vehicular traffic 1010

For the past four or five years the street cars have been practically all of the large pay-as-you-enter type, weighing when loaded about 80,000 lb. Previous to that time cars of all sizes and types were used, with the heaviest weighing about 50,000 lb. loaded.

EXTENT OF DAMAGE

Within the past three years the condition of the brow in the first and second miles, and especially the first mile, has become very bad. The pavement for a distance of from 6 in. to 4 ft. from the rail has been broken down and dips below the tops of the rails. Between the rails the granite blocks have also dropped down to a considerable extent, though not as badly as on the outside. In general appearance it would seem as if the entire right-of-way had been dropped from 1 to 2 in., with the resultant disintegration of the pavement. At intervals humps or blisters were in evidence on the pavement, generally in the vicinity of the gutters. These humps were from 3 to 20 ft. in length and rose above the general surface of the pavement from 2 to 6 in. Adjoining such humps the surface of the pavement was invariably broken down and depressed.

After much correspondence between the proper city authorities and the contractor for the original work in the fall of 1911 and early part of 1912, the contracting company, one of the largest and most responsible in the city of Chicago, and a company which has had an irreproachable reputation, refused to make further repairs. It stated that the railway construction was not strong enough to withstand the heavy cars now in use and that they were not contemplated at the time the pavement was built.

If the pavement had not been repaired at once it would certainly have been destroyed from curb to curb within a few months. An agreement was therefore made between the city and the contractor that the contractor should make the repairs at once and that the actual cost of the repairs should be deposited in escrow awaiting the final decision of the courts.

Repairs of the pavement were begun immediately, and a thorough investigation of the causes of the trouble was made. Since the concrete was exposed on the outside of the rails for the purpose of making repairs, very accurate measurements were taken at frequent intervals to observe the actual contour of the foundation, and minute investigation was made as to the condition of the concrete immediately adjoining the track—in other words, along the brow. This concrete was almost always found to be in excellent condition as regards the material. It was sound and unbroken except that for about 20 per cent of the longitudinal distance and immediately adjoining the bottom of the rail it had become shattered. The same condition as to concrete was found between rails, though it was noted that only over ties was the concrete usually disturbed.

The testimony of all the witnesses was universally to the effect that the concrete foundation was in excellent condition. The street railway company testified that in very few cases had they found broken concrete. In the spring of 1913 they had repaired the pavement between their rails and had shimmed their track whenever necessary. These shims consisted of iron plates from 1/32 in. to ½ in. thick, but by far the greater number used were of the smaller size, and only in very few cases were the ½-in. shims employed. Where these were used there had been cuts made in the pavement by the public-utility companies.

It was also brought out in the case by testimony of city employees and by the contractor that the concrete when originally laid had been surfaced to three stakes set across the half roadway between the track and the curb, one stake being set at the end of the ties, one at the quarter point and one at the gutter. No allegation was made by the city that the material or the thickness of the foundation was defective in any way. It was very clearly demonstrated, however, that the concrete midway between the brow and the gutter was almost universally from ¼ in. to 1 in. higher than the concrete at the rails. In other words, either the track had gone down or the concrete had not been carefully laid to grade. It had also been clearly shown that the concrete was in excellent condition, that it was not at any time broken or shattered except for a distance of 2 in. or 3 in. adjoining the rail in about 20 per cent of the length of the street.

In the investigation of the foundation, three large openings were made in the pavement entirely through the concrete to the subgrade and the thickness was very carefully measured. These holes, which were taken at distances apart of about 2000 ft. on alternate sides of the street, exposed the contour both of the top and bottom concrete. They showed, first, that the concrete was sound and unbroken; second, that at its thickest point, which was the high point of the surface, the concrete was fully 7 in. thick; third, that the bottom of the concrete foundation was below the theoretical bottom as shown in the original ordinance and plans, while the top was above the theoretical line established as the top of the foundation. Both the theoretical top and bottom were established for these points by assuming the present top of rail elevations to be at original grade.

THEORY OF CAUSE OF TROUBLE

From this investigation it was concluded that the railway tracks did not settle appreciably. After six years' use under heavy traffic the only work necessary to put the track in first-class line and grade was an occasional shim 1/16 in. thick. No decided depressions of the track were found. It is inconceivable that the track could settle uniformly from 1 to 2 in. without breaking the concrete around the ties and back of the rails and without badly distorting both line and grade.

It is undeniable that at present the surface of the concrete midway between the quarter and the brow (half way between stakes as set) is from ¼ in. to 1 in. above the concrete abutting the rails. Yet the concrete is sound and unbroken. When this condition exists any water getting between the blocks and the foundation cannot drain away through the sand bed to the sewer inlets in the gutter. Traffic pounding the blocks and street cars pounding the rails—all act as the plunger of a pump and the sand is forced up through the joints to the surface of the pavement and then blown away. In a short time the blocks of the brow pavement drop, and then the wheeled traffic pushing and pounding on the distorted blocks, tilted toward the rails, gradually forces the sand back toward the curb, forming the large blisters previously described. Some of these blisters when opened showed a depth of 6 in. of sand at their high point.

WHY HIGH FOUNDATIONS?

It may be asked why the concrete foundations should be high between the stakes. It was believed that the concrete spreaders on a street having such a flat profile and section kept the concrete high at the point in question. The cross-section was so flat at this point of the curve and the instructions were that there must not be any depressions in the base. Consequently the men instinctively went to the other extreme and made it slightly higher. During construction it passed unnoticed, for as soon as the concrete set the sand bed was roughly spread on it to protect it from street traffic using the railway right-of-way.

THE REMEDY

The remedy is plain. Drainage must be perfect. If it is, there will be little trouble with any modern brow pavement, provided the street railway has a foundation at all adequate for its purposes. A dip in the foundation toward the rails of ¼ in. to 1 in. in 3 ft. may seem a small thing to many engineers, but if no water is held in the sand bed there will be no hydraulic action caused by the traffic. It is not a question of whether or not a sand cushion or a mortar bed is placed under the blocks. A mortar bed under constant pounding will pulverize and the same action take place. It is the old question of perfect drainage. Water is the great enemy of all street pavements. The more nearly the actual drainage conforms to the theoretical requirements, the more perfect the wearing surface will be and will remain under the heaviest traffic.

Typhoons and Philippine Transmission Lines

From June to October of each year the Philippine Islands are subject to typhoons which occasionally interrupt electric service by blowing débris against transmission lines and poles. These whirlwinds are usually very violent and occur without warning, uprooting trees, demolishing houses, sucking up large quantities of water, and sometimes even swamping ships. Because of their vertical, gyratory movement, however, they are not as destructive to transmission lines as equivalent horizontal gusts or gales of wind would be, except when they drop entrained débris on the lines or trail loose branches of trees through the conductors. The Manila Electric Railroad & Light Company reports that these disturbances do little damage to its trolley wires unless loose branches are flying through the air. Ordinarily the typhoons cause about the same interference with operation as would a fairly bad snow and sleet storm in the States.

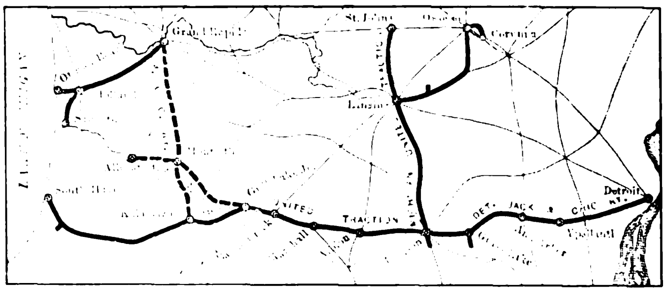
Third-Rail 2400-Volt Construction on the New Michigan & Chicago Railway

This High-Speed Line Connecting Kalamazoo and Grand Rapids Will Be the First Electric Railway in the World to Use a 2400-Volt Third-Rail—The Line Will Be Placed in Operation Next Autumn

Another long stride in the advance of direct-current voltages for third-rail operation will be taken when the new Michigan & Chicago Railway's 2400-volt line is completed. When ready for operation this line will include 91 miles of single track in southern Michigan, connecting Kalamazoo and Grand Rapids, and also Allegan and Battle Creek. That portion of the line between Kalamazoo and Grand Rapids, 49 miles in length, is being newly constructed throughout. The line between Allegan and Battle Creek, 42 miles long, is an old steam road purchased from the Michigan Central Railroad and it is now being electrified for 2400-volt, third-rail operation.

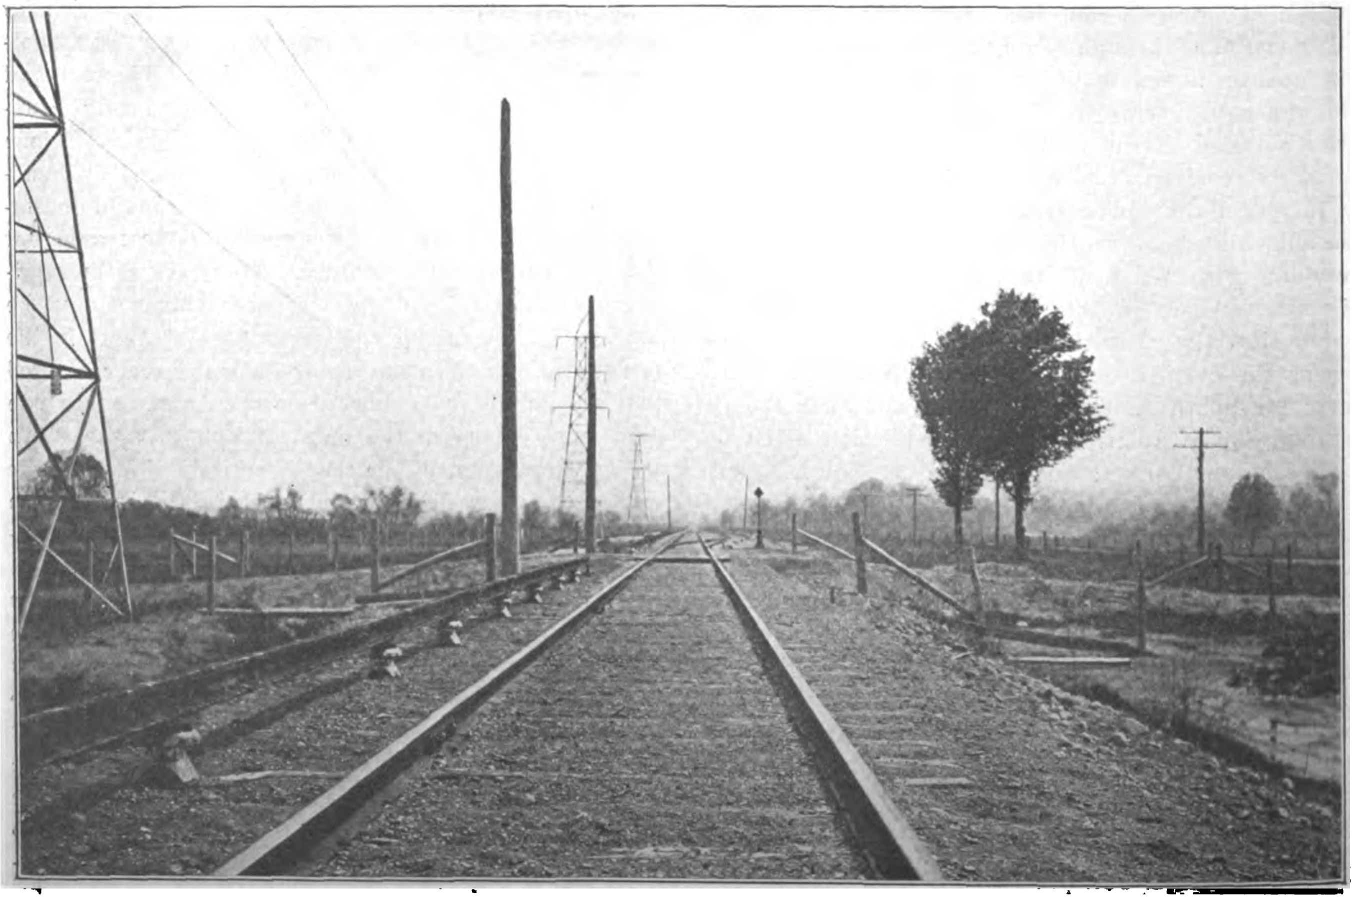
Standards adopted for the construction of this new line provide for high speed with 3 deg. maximum curves and 1 per cent maximum grades. All track, including main line and sidings, is being laid with 80-lb. A. S. C. E. rail on 6-in. x 8-in. x 8-ft. cedar ties, spaced twenty to a 33-ft. rail. Every sixth tie is 10 ft. long, the additional length being provided to furnish support for the third-rail. All sidings are being made double end with No. 12 turnouts having 90-ft. leads, and each siding provides 600 ft. of track in the clear. Both side tracks and main tracks are laid on from 6 to 8 in. of gravel ballast distributed in sufficient quantities to provide a liberal shoulder. Track bonding includes compressed terminal cross-bonds and exposed, Type J, Ohio Brass bonds at all joints.

In order to adhere to the track and roadway standards the grading quantities per mile averaged approximately 20,000 cu. yd., making the total for the new 49-mile line amount to about 1,000,000 yd. The subgrade standards provided for a 100-ft. private right-of-way, and a 16-ft. roadbed in cuts and fills with ample provision for drainage in the former. All waterways under the subgrade are provided with permanent structures. Where reinforced concrete pipe would not supply a sufficiently large opening, reinforced concrete, flat-top arches were constructed. In a few instances the spans were too long for this design and at these points through girders with ballast decks were installed.



Electric Ry Journal

MICHIGAN & CHICAGO RAILWAY—MAP OF THE SYSTEM



MICHIGAN & CHICAGO RAILWAY—VIEW SHOWING THIRD-RAIL AND TRACK CONSTRUCTION

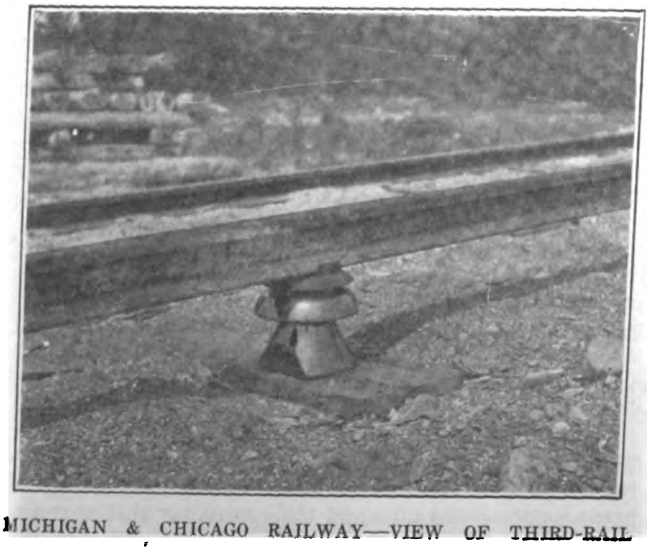
At the present time two bridges are under construction, one over the Kalamazoo River at Kalamazoo, and the other over the Grand River at Grand Rapids. Both of these are important structures, as they provide direct entrance to the north and south terminals of the new line. The bridge at Grand Rapids is a permanent one that rests on concrete piers and abutments. The one at Kalamazoo is a timber trestle with one set of through girders. A temporary structure was provided at the latter point in order to permit a more thorough study of the waterway requirements before a permanent bridge is provided.

2400-VOLT, THIRD-RAIL DETAILS

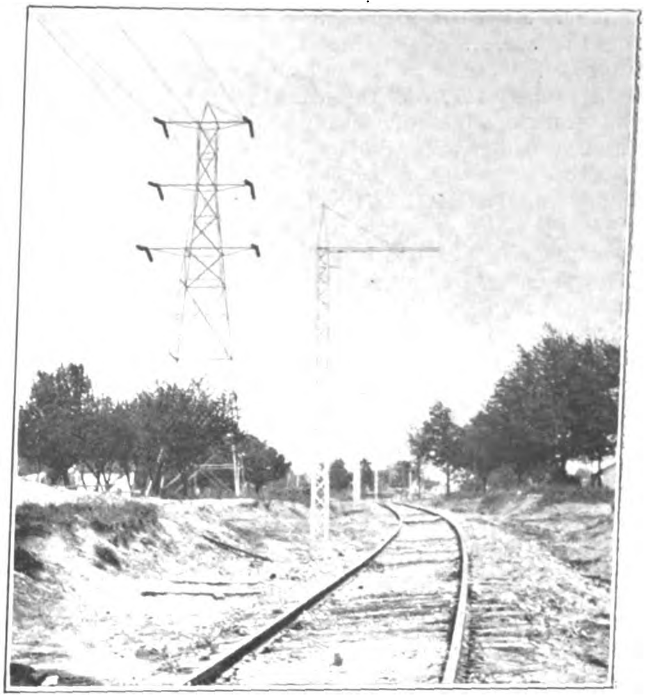
Undoubtedly the most interesting part of the construction of this new line is found in the manner of supporting and insulating the 2400-volt third-rail. Practically all of the third-rail is now in place, and tests are now being conducted to determine the best method of providing an insulated guard for it. As shown in the accompanying illustration the third-rail is installed on special insulators, which are 8½ in. high and are provided with a single petticoat 9⅓ in. in diameter. After the long ties have been accurately adzed to insure a uniform third-rail surface, a small rectangular casting is fastened to the tie with a lag screw. A pocket in the base of the third-rail insulator fits snugly over this base casting. A similar pocket in the top of the insulator takes a malleable iron saddle casting provided with lugs which exactly span the third-rail base. Both the insulator and the third-rail are held in position by their own weight, and the rail is permitted to move freely in accordance with the effects of expansion and contraction.

Prior to adopting the third-rail clearance a careful study was made of a number of Eastern steam-road electrifications that use third-rails in order to determine what clearance would be ample for all classes of equipment. As a result of this study the third-rail was placed at a horizontal distance of 32 in. from the adjacent track rail and 8½ in. above the track-rail surface. This clearance is believed to be ample for any steam-road equipment on tangent track, but at turnouts it was found necessary to depress the third-rail approximately to the same elevation as that of the track rail to insure clearance as a car passes over the switch points into the lead curve. All third-rails are stub-ended at crossings, and poles are set each side to support an overhead contact wire.

Through the cities and villages where the line leaves the 100-ft. private right-of-way, or where it is necessary to provide team tracks and station facilities, the propulsion current is carried on overhead trolley wires. At these locations galvanized structural poles with mast-arms are provided. The poles are 35 ft. long and are set with 18 in. of concrete at the bottom of the hole and 18 in. at the top. The sections of overhead trolley which are carried on the mast-arm construction are dead-ended by connecting the trolley ends to a pair of structural-steel galvanized poles, one set each side of the track. A view of this class of construction is shown in one of the illustrations.



MICHIGAN & CHICAGO RAILWAY—VIEW OF THIRD-RAIL CONSTRUCTION



MICHIGAN & CHICAGO RAILWAY—VIEW SHOWING OVERHEAD TROLLEY CONSTRUCTION THROUGH CITIES

As the third-rail clearance was unusually wide the use of a specially designed third-rail shoe was required to provide for operation through public streets. Accordingly, the shoe was arranged to operate with a pneumatic folding mechanism under the control of the motorman. Since practically the entire line is on private right-of-way, even well into the cities of Kalamazoo, Battle Creek and Grand Rapids, these third-rail shoes need be in the folded position only during the short intervals when a car is operating over the streets at these terminals.

SUPPLY OF ENERGY

According to present plans the whole line will be fed from Kalamazoo, Battle Creek and Grand Rapids at 2400 volts d.c., and no additional feeder other than the 80-lb., A. S. C. E., low-carbon third-rail will be employed. In case energy supplied from these three points is insufficient, 42,000-volt and 70,000-volt a.c. transmission lines that are already installed on steel towers along the private right-of-way may be tapped to supply energy to a substation at some intermediate point. This transmission line forms a part of the network of lighting and power lines of the Commonwealth Power & Light Company, owned and operated by the same holding company as the one which owns the new railway line.

PRESENT STATUS OF WORK

The work completed up to June 1 includes all the track and roadway except that portion in the immediate vicinity of the cities of Kalamazoo and Grand

Rapids. All third-rail is now installed but is awaiting the selection and installation of the protecting guard. Entrance to Kalamazoo and to Grand Rapids is arranged for, but the work was delayed both by the franchise negotiations and the construction of the two bridges mentioned.

The electrification of the steam road between Allegan and Battle Creek has been started. Third-rail ties are being placed and the overhead construction through the cities and villages is well under way. Three new telephone circuits will be provided on both divisions of the line. One will be used for train dispatching, one for commercial purposes and the third for power dispatching. These lines are being constructed on separate wooden poles. The overhead transmission power line is complete, but will not be put in service until the railway is ready for operation.

When the Michigan & Chicago Railway is completed it will form a part of the Michigan Railway Company's system, which is operated by the officers of the Michigan United Traction Company. This system includes the Michigan United Traction Company that operates a 1200-600-volt d.c. overhead and third-rail line; the Grand Rapids, Holland & Chicago Railway, a 1200-600-volt overhead line; the Saginaw-Flint Railway, a 1200-600-volt overhead and third-rail line, and the new Michigan & Chicago Railway, which will be a 2400-1200-volt third-rail line. In total length this system comprises approximately 470 miles of single track, practically all of which will be operated at 1200 volts on private right-of-way, excepting the Michigan & Chicago Railway, which will start at 1200 volts and later be raised to 2400 volts.

Responsibility for Pavement Repair Along Car Tracks in Chicago

In an article by P. E. Green, consulting engineer of Chicago, printed in the *Engineering Record*, the question of pavement deterioration along street railway tracks in Chicago is discussed. An abstract follows:

One of the most perplexing problems in modern city pavement is the maintenance of a first-class pavement along street railway tracks. In practically all cities this trouble is encountered. The city of Chicago has lately won an exceedingly important case in litigation on this point. The decision means hundreds of thousands of dollars to the city and to various contractors. It will undoubtedly be appealed and hence will not be finally decided for two or three years.

In order that the following discussion may be clear, the "brow pavement" is defined as that part of the paving area within a couple of feet and outside of the street railway tracks. The "quarter point" or "quarter" is the point midway between the outer rail and the curb.

Lincoln Avenue, where this question arose, is one of the principal secondary business streets of the North Side of Chicago. It is a diagonal street and accommodates a heavy traffic, both vehicular and street railway. It is paved with creosoted-wood blocks on a sand bed 1 in. in thickness and a 6-in. concrete foundation. The pavement was constructed in three sections—the first mile in 1907, the second mile in 1908 and the third mile in 1909. The space between the rails and tracks is paved with granite block for the first two miles and with wood block in the third. The creosoted-wood block pavement is laid in rows of approximately 45 deg. to within 4 in. of the rail. Most of the brow has a single longitudinal block laid parallel with the rail. On the west side of the first mile, however, the diagonal rows extend to the edge of the rail.

The railway construction is what is known as "Type 3," as adopted by the Board of Supervising Engineers, Chicago Traction. This type of track consists of a lower course of 8 in. of crushed stone upon which the ties and rails are laid. The ties and bases of the rails are covered and surrounded by 8 in. of concrete. On the top of the concrete is spread the sand bed, and the pavement is laid on this. In the first mile mentioned, in addition to this crushed stone, crushed cobbles were placed in the bottom of the track trench and the whole was thoroughly rolled with an Iroquois 10-ton roller. Particular attention is called to this type of construction, as its ability to stand up under the traffic was a question of the problem discussed in the following paragraphs. The rails themselves were of the 129-lb. Chicago section.

In longitudinal profile the street is exceedingly flat, there being only about 3 ft. difference in elevation in 3 miles. The roadway of Lincoln Avenue is 42 ft. wide from curb to curb. Since the railway right-of-way is 16 ft. wide, the pavement is approximately 13 ft. wide on each side of the railway right-of-way.

TRAFFIC CENSUS

Traffic is heavier in the first mile, especially as regards the railway traffic, than in the second or third mile. This is because Lincoln Avenue is known as a through-route street, and at the end of the first mile some of the cars turn off the avenue. A census of the traffic taken between the hours of 7.30 a. m. and 10 p. m. is given in the table.

CENSUS OF TRAFFIC BETWEEN 7.30 A. M. AND 10 P. M.

First mile	Street cars 1041,	Vehicular traffic 1500
Second mile	Street cars 746,	Vehicular traffic 1814
Third mile	Street cars 457,	Vehicular traffic 1010

For the past four or five years the street cars have been practically all of the large pay-as-you-enter type, weighing when loaded about 80,000 lb. Previous to that time cars of all sizes and types were used, with the heaviest weighing about 50,000 lb. loaded.

EXTENT OF DAMAGE

Within the past three years the condition of the brow in the first and second miles, and especially the first mile, has become very bad. The pavement for a distance of from 6 in. to 4 ft. from the rail has been broken down and dips below the tops of the rails. Between the rails the granite blocks have also dropped down to a considerable extent, though not as badly as on the outside. In general appearance it would seem as if the entire right-of-way had been dropped from 1 to 2 in., with the resultant disintegration of the pavement. At intervals humps or blisters were in evidence on the pavement, generally in the vicinity of the gutters. These humps were from 3 to 20 ft. in length and rose above the general surface of the pavement from 2 to 6 in. Adjoining such humps the surface of the pavement was invariably broken down and depressed.

After much correspondence between the proper city authorities and the contractor for the original work in the fall of 1911 and early part of 1912, the contracting company, one of the largest and most responsible in the city of Chicago, and a company which has had an irreproachable reputation, refused to make further repairs. It stated that the railway construction was not strong enough to withstand the heavy cars now in use and that they were not contemplated at the time the pavement was built.

If the pavement had not been repaired at once it would certainly have been destroyed from curb to curb within a few months. An agreement was therefore made between the city and the contractor that the contractor should make the repairs at once and that the actual cost of the repairs should be deposited in escrow awaiting the final decision of the courts.

Repairs of the pavement were begun immediately, and a thorough investigation of the causes of the trouble was made. Since the concrete was exposed on the outside of the rails for the purpose of making repairs, very accurate measurements were taken at frequent intervals to observe the actual contour of the foundation, and minute investigation was made as to the condition of the concrete immediately adjoining the track—in other words, along the brow. This concrete was almost always found to be in excellent condition as regards the material. It was sound and unbroken except that for about 20 per cent of the longitudinal distance and immediately adjoining the bottom of the rail it had become shattered. The same condition as to concrete was found between rails, though it was noted that only over ties was the concrete usually disturbed.

The testimony of all the witnesses was universally to the effect that the concrete foundation was in excellent condition. The street railway company testified that in very few cases had they found broken concrete. In the spring of 1913 they had repaired the pavement between their rails and had shimmed their track whenever necessary. These shims consisted of iron plates from 1/32 in. to ½ in. thick, but by far the greater number used were of the smaller size, and only in very few cases were the ½-in. shims employed. Where these were used there had been cuts made in the pavement by the public-utility companies.

It was also brought out in the case by testimony of city employees and by the contractor that the concrete when originally laid had been surfaced to three stakes set across the half roadway between the track and the curb, one stake being set at the end of the ties, one at the quarter point and one at the gutter. No allegation was made by the city that the material or the thickness of the foundation was defective in any way. It was very clearly demonstrated, however, that the concrete midway between the brow and the gutter was almost universally from ¼ in. to 1 in. higher than the concrete at the rails. In other words, either the track had gone down or the concrete had not been carefully laid to grade. It had also been clearly shown that the concrete was in excellent condition, that it was not at any time broken or shattered except for a distance of 2 in. or 3 in. adjoining the rail in about 20 per cent of the length of the street.

In the investigation of the foundation, three large openings were made in the pavement entirely through the concrete to the subgrade and the thickness was very carefully measured. These holes, which were taken at distances apart of about 2000 ft. on alternate sides of the street, exposed the contour both of the top and bottom concrete. They showed, first, that the concrete was sound and unbroken; second, that at its thickest point, which was the high point of the surface, the concrete was fully 7 in. thick; third, that the bottom of the concrete foundation was below the theoretical bottom as shown in the original ordinance and plans, while the top was above the theoretical line established as the top of the foundation. Both the theoretical top and bottom were established for these points by assuming the present top of rail elevations to be at original grade.

THEORY OF CAUSE OF TROUBLE

From this investigation it was concluded that the railway tracks did not settle appreciably. After six years' use under heavy traffic the only work necessary to put the track in first-class line and grade was an occasional shim 1/16 in. thick. No decided depressions of the track were found. It is inconceivable that the track could settle uniformly from 1 to 2 in. without breaking the concrete around the ties and back of the rails and without badly distorting both line and grade.

It is undeniable that at present the surface of the concrete midway between the quarter and the brow (half way between stakes as set) is from ¼ in. to 1 in. above the concrete abutting the rails. Yet the concrete is sound and unbroken. When this condition exists any water getting between the blocks and the foundation cannot drain away through the sand bed to the sewer inlets in the gutter. Traffic pounding the blocks and street cars pounding the rails—all act as the plunger of a pump and the sand is forced up through the joints to the surface of the pavement and then blown away. In a short time the blocks of the brow pavement drop, and then the wheeled traffic pushing and pounding on the distorted blocks, tilted toward the rails, gradually forces the sand back toward the curb, forming the large blisters previously described. Some of these blisters when opened showed a depth of 6 in. of sand at their high point.

WHY HIGH FOUNDATIONS?

It may be asked why the concrete foundations should be high between the stakes. It was believed that the concrete spreaders on a street having such a flat profile and section kept the concrete high at the point in question. The cross-section was so flat at this point of the curve and the instructions were that there must not be any depressions in the base. Consequently the men instinctively went to the other extreme and made it slightly higher. During construction it passed unnoticed, for as soon as the concrete set the sand bed was roughly spread on it to protect it from street traffic using the railway right-of-way.

THE REMEDY

The remedy is plain. Drainage must be perfect. If it is, there will be little trouble with any modern brow pavement, provided the street railway has a foundation at all adequate for its purposes. A dip in the foundation toward the rails of ¼ in. to 1 in. in 3 ft. may seem a small thing to many engineers, but if no water is held in the sand bed there will be no hydraulic action caused by the traffic. It is not a question of whether or not a sand cushion or a mortar bed is placed under the blocks. A mortar bed under constant pounding will pulverize and the same action take place. It is the old question of perfect drainage. Water is the great enemy of all street pavements. The more nearly the actual drainage conforms to the theoretical requirements, the more perfect the wearing surface will be and will remain under the heaviest traffic.

Typhoons and Philippine Transmission Lines

From June to October of each year the Philippine Islands are subject to typhoons which occasionally interrupt electric service by blowing débris against transmission lines and poles. These whirlwinds are usually very violent and occur without warning, uprooting trees, demolishing houses, sucking up large quantities of water, and sometimes even swamping ships. Because of their vertical, gyratory movement, however, they are not as destructive to transmission lines as equivalent horizontal gusts or gales of wind would be, except when they drop entrained débris on the lines or trail loose branches of trees through the conductors. The Manila Electric Railroad & Light Company reports that these disturbances do little damage to its trolley wires unless loose branches are flying through the air. Ordinarily the typhoons cause about the same interference with operation as would a fairly bad snow and sleet storm in the States.

Traffic Investigation in Denver

Counts of All Vehicular Traffic Made by Forty-four Men on the Thirty-six Streets Entering the Business District of Denver Showed that 53 Per Cent of All Travelers Used the Street Cars—If Automobilists Used the Car Service the Annual Gross Revenues of the Railway Would Increase Nearly $440,000

BY ROGER W. TOLL, CHIEF ENGINEER DENVER TRAMWAYS

Most traction companies are interested in knowing how the people of their city travel, and what proportion of the travel is carried by the street cars. Thus, the number of passengers carried by automobiles is often conjectured, but usually there are very few data upon which to base an estimate upon this and similar questions. To determine this information in the case of Denver, a traffic investigation was recently conducted under the direction of John A. Beeler, vice-president and general manager of the Denver Tramway Company. The following synopsis of the methods used in making the investigation and the results obtained are presented:

BOUNDARIES OF ASSUMED BUSINESS DISTRICT

The business district, as assumed for the purposes of this investigation, is bounded by the lines shown on the map on the opposite page.

East side of Broadway from Colfax Avenue to Twentieth Avenue.

Northwest side of Welton Street from Twentieth Avenue to Twentieth Street.

Southwest side of Twentieth Street from Welton Street to the Platte River.

Center line of the Platte River from Twentieth Street to Cherry Creek.

Center line of Cherry Creek from the Platte River to West Colfax Avenue.

South side of West Colfax Avenue from Cherry Creek to Broadway.

The area included within this business district is 0.87 sq. mile. The total area of the city and county of Denver is 58.75 sq. miles. The area of the business district, here assumed, is slightly less than 1½ per cent of the area of the entire city. The district includes not only the retail business district but the greater part of the wholesale district and a portion of the railroad yards.

CLASSIFICATION OF TRAFFIC AND OBSERVATIONS

All street traffic, exclusive of street car passengers, was grouped in accordance with the following classification:

A—Persons in passenger automobiles.
B—Persons in freight automobiles.
C—Persons on motorcycles.
D—Persons on bicycles.
E—Persons in horse-drawn passenger vehicles.
F—Persons in horse-drawn freight vehicles.
G—Pedestrians.

The accompanying blank shows the form used by the observers on this work.

There are thirty-six public thoroughfares entering this business district. At a few locations the travel was so light that one observer recorded the travel on two streets. At five locations the travel was so heavy that two observers were required, one to record pedestrians and the other to record vehicle traffic. The observations were taken by forty-four men, most of whom were trainmen. Half of the men were on duty from 6 a. m. until 3 p. m.; they were then relieved by the other half, who were on duty from 3 p. m. until midnight. The observations were therefore continuous from 6 a. m. until midnight, a period of eighteen hours. The observations covered a period of two days, as the number of available men was insufficient to cover all locations in one day. These days were Monday, May 4, and Tuesday, May 5.

DENVER TRAFFIC STUDY—FORM OF RECORD USED BY THE DENVER TRAMWAY'S OBSERVERS

In order to see if the traffic conditions were similar during the two days named, the traffic at two locations was observed by the same men on both days. One of these two locations showed a decrease of travel, while the other showed an increase. It was concluded that no great error was involved by combining the records of two days so as to represent a typical day. Tuesday, May 5, was therefore assumed as the typical day. The weather conditions for the days on which observations were taken were good and may be considered as typical for that time of year.

As stated above, the number of vehicles entering and leaving the business district was recorded, as well as the number of persons in the vehicles. The totals of the vehicle count are shown below, together with the average number of persons carried by each class of vehicle.

Class of Traffic	Inbound Trips	Outbound Trips	Total Trips	Per Cent of Total Vehicles	Average Persons per Vehicle
Passenger automobiles...	8,489	8,723	17,212	26.0	1.79
Freight automobiles.....	1,355	1,275	2,630	4.0	1.42
Motorcycles	1,730	1,722	3,452	5.2	1.14
Bicycles	9,325	9,342	18,667	28.2	1.01
Horse-drawn passenger vehicles	1,787	1,672	3,459	5.2	1.36
Horse-drawn freight vehicles	10,447	10,300	20,747	31.4	1.22
Total vehicles.......	33,133	33,034	66,167	100.0	1.47

The number of vehicles entering and leaving the business district should be practically equal for any one day. The foregoing figures afford an indication of the percentage of error of this investigation.

The most numerous vehicles entering and leaving the business district are the horse-drawn freight vehicles, including delivery wagons of all sorts. This class constitutes 31 per cent of the total number of vehicles. It is surprising to find the bicycles next in number, being 28 per cent of the total, and even exceeding passenger automobiles, which constitute 26 per cent of the total.

Horse-drawn passenger vehicles constitute 5 per cent and motorcycles 5 per cent and freight automobiles 4 per cent of the total. The number of passing bicycles was more than five times the number of passing motorcycles, and the number of passing passenger automobiles was more than six times the number of passing freight automobiles.

Thirteen per cent of the 10,000 daily trips made by automobiles in and out of the district are for freight purposes. Of the total number of automobiles in use in the city, probably about the same percentage are freight autos. Of the horse-drawn vehicle trips, 86 per cent were for freight purposes. Of the total vehicle trips, 35 per cent were for freight purposes. The horse-drawn vehicle trips are in excess of the automobile trips, being 37 per cent of the total number of vehicles, as compared with 30 per cent for the automobiles.

The State law that went into effect in 1913 requires the registration, at the beginning of each year, of all automobiles and motorcycles. The records of the registrations in Denver County are as follows:

Total for 1913	
Individual licenses	4,793
Dealer licenses	175
Total automobiles	4,968
Motorcycles	1,013
Issued Jan. 1 to May 5, 1914.	
Individual licenses	4,630
Dealer licenses	169
Total automobiles	4,799
Motorcycles	927

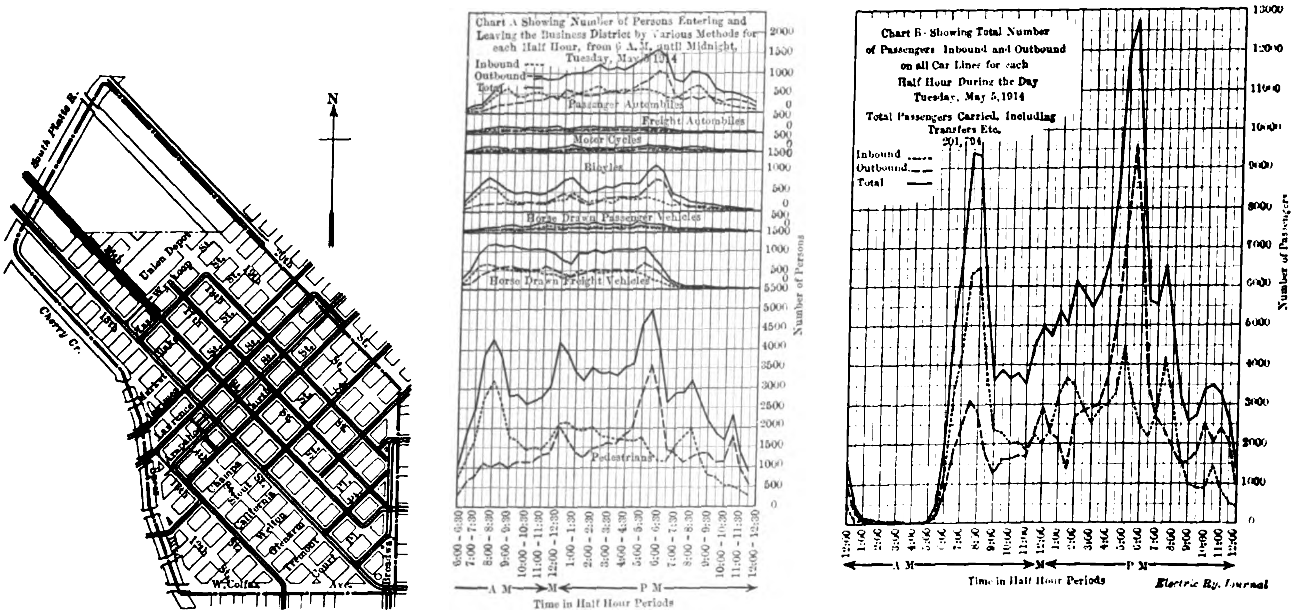
The figures for May 5 represent the number of licenses issued at the time of this traffic investigation. The number of licenses that will have been issued by Dec. 31 of this year will exceed the number issued during 1913. No reliable data are available as to the number of automobiles in use during years prior to 1913.

From the foregoing data it is assumed that about 5000 automobiles and 1000 motorcycles are now in use in Denver. If 13 per cent of the automobiles are in freight service, there are about 650 freight autos and 4350 passenger autos in use in the city.

The number of automobiles and motorcycles entering and leaving the business district is shown below, together with the number of round trips per machine, based upon the estimated number of machines in use:

	In-bound	Out-bound	Average Number of Round Trips	Estimated Number in Use	Number of Round Trips per Machine
Passenger automobiles	8,489	8,723	....	....	..
Freight automobiles	1,355	1,275	....	....	..
Total automobiles	9,844	9,998	9,921	5,000	2.0
Motorcycles	1,730	1,722	1,726	1,000	1.7

A certain percentage of the registered automobiles are not in daily use, and a certain percentage of those in use do not reach the business district, so that the actual number of round trips per machine in city use is doubtless more than that here shown. It is also true that some of the automobiles used in the business district are owned and registered in the counties adjoining Denver and are therefore not included in the estimated number of automobiles owned in Denver.



DENVER TRAFFIC STUDY—THE BUSINESS DISTRICT OF DENVER AND THE TWO TRAFFIC CHARTS MADE TO SHOW THE TRAVEL ON ONE BUSINESS DAY

Number of Persons Inbound and Outbound

The combined records of the observations taken at the thirty-six thoroughfares give the total number of persons, entering and leaving the business district daily, as 194,456. The following tabulation shows the total results for each class of traffic, inbound and outbound, together with the percentage that each class of traffic bears to the total traffic. This tabulation includes all classes of traffic with the exception of passengers carried on the electric cars:

Number of Persons Entering and Leaving the Business District Daily by Various Methods, Other than Street Car

Class of Traffic	Inbound	Outbound	Total	Per Cent
Persons in passenger automobiles	15,540	15,264	30,804	15.9
Persons in freight automobiles..	1,938	1,797	3,735	1.9
Persons on motor cycles........	1,967	1,956	3,923	2.0
Persons on bicycles.............	9,348	9,602	18,950	9.7
Persons in horse-drawn passenger vehicles	2,430	2,280	4,710	2.4
Persons in horse-drawn freight vehicles	12,733	12,611	25,344	13.5
Pedestrians	56,251	50,739	106,990	55.0
Total	100,207	94,249	194,456	100.0

It will be noted that the number of persons inbound is 100,207, while the number outbound is 94,249. The difference of nearly 6000 is seen to be due principally to the pedestrian class, as the number of pedestrians inbound is about 5500 greater than the number of pedestrians outbound. This would indicate that more people walk to business than walk home. There is a similar excess of about 300 in the number of persons carried to the business district in passenger autos.

The inbound and outbound records for other classes of traffic are fairly consistent. The excess of 250 in outbound bicycles is probably due in part to those reaching the business district before 6 a. m., for the charts indicate that bicycle riders are early risers.

The accompanying chart "A" shows graphically the number of persons entering and leaving the business district during each half-hour of the day by each class of transportation. These curves show the peaks due to inbound traffic in the morning, outbound traffic in the late afternoon and traffic in both directions during the middle of the day and also the evening.

Car Traffic

To have made this investigation complete it would have been interesting to have ascertained the number of passengers on each car as it entered and left the business district throughout the day. It is impracticable to get an accurate count of this nature, particularly during the rush hours. The best statistics that are available for comparison with street traffic are the figures of total passengers carried in the city, regardless of the business district.

While this comparison is the best available, it is on a somewhat different basis, since a certain proportion of the passengers carried on cars do not enter the business district. There are a number of factories, shops, industries and minor centers of trade that are not included in the business district. Persons going to these locations may or may not pass through the business district. The car data therefore include all of that class of traffic in the entire city, while the street traffic data are confined to the business district. The passengers carried by interurban lines outside of the city are excluded from the totals.

The percentage of passengers carried by the lines passing through the central loop and the lines passing at various distances from the central loop was found to be as follows:

Passengers carried by lines passing through the central loop	45.5 per cent
Passengers carried by lines passing adjacent to the central loop	17.5 per cent
Passengers carried by lines passing one block from the central loop	30.2 per cent
Passengers carried by lines passing two or three blocks from the central loop....................	6.8 per cent
Total	100.0 per cent

Chart "B" shows graphically the number of persons riding on the cars during each half-hour of the day. The data for this chart were obtained from the records of the fare registers. These records give the number of passengers carried on each car-trip, inbound and outbound, together with the time of the car at each end of the line. The time that each car crossed the boundary of the business district was then computed and the car-trips were then grouped in half-hour periods. By this method the chart represents the number of passengers carried on cars entering and leaving the business district during each half hour, and the chart is therefore on the same time basis as the other traffic charts. As previously stated, that car traffic includes all passengers carried in the entire city, though a certain proportion of these passengers do not cross the boundaries of the business district.

Six of the thirty-one lines are crosstown lines and no data are available as to the inbound and outbound passengers on these lines, since a single trip across town includes both classes of passengers. The total number of passengers carried by these crosstown lines during each half-hour was divided into inbound and outbound in the same proportion that was found to exist between the inbound and outbound passengers carried on the other lines during the same half-hour of the day.

An examination of the chart showing car passengers leads to the following conclusions:

The morning load was heavy from 6.30 to 9 o'clock, and reached its peak from 7.30 to 8, during which half hour, 9400 passengers were carried, inbound and outbound.

The afternoon load was heavy from 4 o'clock to 6.30, and reached its peak from 5.30 to 6, during which half hour 12,800 passengers were carried, inbound and outbound. The time of these peaks is known to vary with the season of the year, but the chart may be considered typical for a week-day during the month of May.

The outbound traffic shows a small peak from 12 o'clock to 12.30 p. m., and the inbound traffic shows a small peak from 1.30 to 2 p. m. This is caused principally by the lunch hour.

The inbound traffic shows a small peak from 7.30 to 8 p. m. and the outbound traffic shows small peaks from 10 to 10.30 p. m. and 11 to 11.30 p. m. These are principally due to evening entertainments in the business district.

It is to be noted that a peak in the inbound traffic is usually accompanied by a smaller peak in the outbound traffic, and vice versa. This is probably due to two causes: First, the people working outside of the business district move in the opposite direction to those working in the business district; second, transfers issued from an inbound car are generally used on an outbound car, so it is to be expected that both directions of traffic will show peaks at about the same time, due to the large percentage of transfers issued.

General travel is heavier in the afternoon than in the morning, indicating a prevalence of afternoon shopping. The travel during the evening peak is about double the travel at any other time of the day except during the morning peak, and more than double the average travel during the day.

The following is a comparison of the inbound and outbound passengers carried during the day:

Inbound	99,345
Outbound	102,449
Total	201,794

The excess of outbound over inbound is 3104, which is in accordance with the previous statement that many people walk to business and ride home on the cars.

Total Traffic

The total daily inbound and outbound traffic is as follows:

Street traffic, inbound............................	100,207	
Car traffic, inbound............................	99,345	
Total inbound		199,552
Street traffic, outbound	94,249	
Car traffic, outbound	102,449	196,698
Total, inbound and outbound............................		396,250

The number of passengers carried on cars during the "owl" period, from midnight to 6 a. m. and during the remaining eighteen hours, from 6 a. m. to midnight, is as follows:

Passengers carried from midnight to 6 a. m.	2,004	1 per cent
Passengers carried from 6 a. m. to midnight	199,790	99 per cent
Total passengers carried	201,794	100 per cent

If this same percentage holds true on other classes of street traffic, then the data obtained by this investigation, which are based on the eighteen hours, from 6 a. m. to midnight, represent about 99 per cent of the total street traffic for a twenty-four hour day.

Combining the number of passengers carried by the cars in the entire city with the street traffic in and out of the business district, we have the following totals and percentages:

Method of Transportation	Number of Persons	Per Cent
Street cars	201,794	50.9
Passenger automobiles	30,804	7.8
Freight automobiles	3,735	0.9
Motorcycles	3,923	1.0
Bicycles	18,950	4.8
Horse-drawn passenger vehicles	4,710	1.2
Horse-drawn freight vehicles	25,344	6.4
Pedestrians	106,990	27.0
Total	396,250	100.0

Eliminating the persons traveling in freight vehicles, the totals and percentages are as follows:

Method of Transportation	Number of Persons	Per Cent
Street cars	201,794	54.9
Passenger automobiles	30,804	8.2
Motorcycles	3,923	1.2
Bicycles	18,950	5.2
Horse-drawn passenger vehicles	4,710	1.3
Pedestrians	106,990	29.2
Total	367,171	100.0

It is interesting to note that the number of passengers carried by street cars is about 53 per cent of the above total.

The receipts per passenger carried for the year 1913 averaged 3.89 cents, since the total number of passengers carried includes those riding on transfers, half fares and miscellaneous tickets. If the 30,804 persons going in and out of the business district by passenger automobiles were all carried on the street cars the revenue would be 30,804×$0.0389, or $1,198.28 a day, or $437,372.20 per year, assuming that the automobile passengers average the same throughout the entire year as for the typical week day on which these data were based.

On the estimate, previously stated, that there are 4350 passenger autos in use in the city, the 30,804 passengers carried by these autos are equivalent to an average of 7.1 passenger-trips per auto per day. The loss of revenue per auto is therefore about 7.1 × 3.89, or 27.6 cents a day, or $100.74 a year, assuming the same average daily number of passengers for the entire year.

TRAVEL COMPARED WITH POPULATION

For the purposes of this investigation, the population of Denver is assumed in round figures at 200,000. The total number of persons riding on cars and going in and out of the business district daily is shown as 396,250. This is equivalent to approximately one trip, in and out, per person per day. In an average household of four or five persons, one person would go to the business district daily and the other members of the household would go occasionally, averaging perhaps two persons per household going to the business district per day. For the entire city, about 100,000 persons would go to the business district per day. This would result in a minimum of 200,000 trips, in and out, per day. The difference between this figure and the figure of 396,250 given above is probably due to trips out and back at noon time, as shown by the accompanying curves, and to the numerous trips, in and out, of a certain portion of the population. The total result is not far from what would be expected.

The number of passenger automobiles in use, estimated at 4350, is equivalent to an average of one automobile for every forty-six persons. Assuming an average of from four to five persons per household, this is equivalent to an average of one automobile to about ten households.

Commonwealth Edison Company Acquires South Chicago Power House Site

The Commonwealth Edison Company, Chicago, Ill., announces the recording of the deeds covering the purchase of about 24 acres of land in South Chicago, on the east side of the Calumet River near the intersection of the Lake Shore and Pennsylvania Railroad tracks entering Chicago. While it is probable that nothing will be built on the site at present, ultimately it will contain a large generating plant, supplementing the output of the present three large, modern steam-turbine generating plants and smaller stations of an older type. The proposed new station will be located on the Calumet River, the commercial highway for water-borne commerce in the southern part of Chicago. The new site is strategically located with respect to railroad transportation and water for condensing purposes.

It has been assumed that the proposed generating plant would be conveniently located in case the steam railroads in that part of Chicago desired to equip their passenger service for electrical operation. However, Samuel Insull, president of the Commonwealth Edison Company, is quoted as saying that his company has no contract with steam railroad companies to supply electrical energy for the operation of trains and that the location of the new plant has nothing to do with the suggested electrification of the railroads. It is simply a part of the general engineering plans of the company to establish generating stations in advantageous locations in different sections of the city. Of course, the plant will be there for railroads and others to avail themselves of its resources if desired.

English Tramway Employees at War

According to *Electrical Engineering*, a very large number of the employees of electric supply tramway and manufacturing companies of Great Britain are now serving in the army and navy and territorials. In many cases arrangements are being made to continue the full pay of the men in the case of married employees and half-pay in the case of single employees. In other instances the difference between the army pay and ordinary wages is being paid, and in still others the company has guaranteed to look after the wives and families of the men. The tramway undertakings are supplying the largest number of men, probably because so many army reservists find employment in this direction. The names of some of the electric railways, with the number of men sent, follow:

London County Council Tramways, 700 men, and an additional 400 men are liable to be called upon as national reservists.

Glasgow Corporation Tramways, 604 men, including many members of the engineering staff.

Birmingham Corporation Tramways, 340 men.

Manchester Corporation Tramways, 346 men.

Metropolitan Electric Tramways, 233 men.

London United Tramways, 150 men.

Liverpool Corporation Tramways, 400 men.

South Metropolitan Electric Tramways and Lighting Company, 33 men.

Cardiff Lighting and Tramways Department, 59 men.

The European War and Export Trade

Statistics of German and British Export Trade in Electrical Apparatus to Different Countries—Opinions of British Technical Papers on Trade Conditions — South American Business Discussed by Prominent Authorities

BRITISH AND GERMAN EXPORT TRADE

STATISTICS SHOW THE AMOUNT AND DESTINATION OF THE ELECTRICAL EXPORTS

Owing to the suspension of most European mail service, the only foreign technical papers now available are those of England. The general tone of the English technical press is one of optimism. While admitting that the present outlook is too serious to be illumined by more than hope, much satisfaction is found in the steadfast way in which the financial institutions of London and the people affected have met the situation without the precipitation of a panic.

Electrical Engineering in its issue of Aug. 13 presents a digest of a German official return showing under classified headings Germany's chief customers for its export trade. The total exports of Germany to all countries for 1913 were of a value of £14,500,000, and the total weight was 133,855 (metric) tons. If all of the German exports going to Austria, Russia and France, the large Continental countries now involved in the war, is deducted from the total a figure of £12,300,000 is obtained, which represents approximately the trade opened to other countries. English electrical exports to Germany, Austria, Russia, France and Belgium during 1913 were only £511,440, the present loss of which English exporters aim to more than counterbalance by participating in the £12,300,000 of trade now lost to Germany.

TABLE I.—SHOWING VOLUME OF GERMAN TRADE IN POUNDS STERLING FOR ELECTRICAL EXPORTS TO ALL COUNTRIES DURING 1913.

Generators, motors, transformers and choking coils:		
Machines, etc., up to 25 kg. in weight	£ 144,350	
Machines, etc, from 25 to 100 kg. in weight	361,000	
Machines, etc., from 100 to 500 kg. in weight	721,000	
Machines, etc., over 500 kg. in weight	1,599,850	
		£2,826,200
Separate armatures and commutators		393,750
Accumulators and parts		286,850
Cable		1,963,400
Arc lamps and mercury vapor lamps		143,000
Arc lamp carbons		491,300
Spare cases and globes, etc., for arc and mercury vapor lamps		21,600
Projectors and reflectors		97,950
Metal filament lamps		2,251,900
Carbon filament and Nernst lamps		167,650
Telegraphic apparatus		48,200
Telephonic apparatus (excluding wireless)		431,800
Electrical fuses, cut-outs, bells, signaling apparatus, etc.		186,700
Apparatus for wireless telegraphy and telephony		82,100
Electrical devices for lighting, power, etc		3,702,350
Electro-medical and dental apparatus		228,200
Electrical measuring instruments, electricity meters and parts		1,211,500
Primary batteries and parts		154,150
Electrical heating and cooking apparatus and parts		83,750
Asbestos, mica and micanite insulators		56,300
Insulating tubes of paper, etc		163,300

Table I, presented herewith, indicates the volume of German export trade in pounds sterling in various electrical and allied commodities for 1913. It will be noted the chief line of German trade has been electrical devices for lighting, power, etc., amounting in value to £3,702,350. Following this is the trade in heavy electrical machinery, including generators, dynamos, transformers and choking coils, valued at £2,826,200; metal filament lamps, £2,251,900; cable, £1,963,400, and electrical measuring instruments, £1,211,500.

Table II shows how the German trade in generators, motors and transformers, in electrical devices for lighting, power, etc., and in electrical measuring instruments, is divided among the world customers of Germany. These items are selected as being those in the classification most closely allied to the electric railway industry. As indicated in the table, Russia ranks first in volume of trade on a ton basis, but Belgium, Austria-Hungary, Great Britain, Argentina, Italy, Spain, France and Japan are not far behind. The heavy export trade by Germany is along the line of generators, motors, transformers, etc., the total volume being 37,279 (metric) tons, while electric light and power devices follow with 21,553 (metric) tons and electrical measuring instruments with 3321 (metric) tons.

TABLE II.—SHOWING DIVISION ON METRIC-TON BASIS OF THREE MAIN LINES OF GERMAN ELECTRICAL EXPORTS TO WORLD COUNTRIES IN 1913.

	Generators, Motors, Transformers and Choking Coils	Electrical Devices for Lighting, Power, etc.	Electrical Measuring Instruments, Electricity Meters and Parts
Russia	3,667	2,924	570
Belgium	3,048	1,465	129

ENGLISH EXPORT TRADE

The Electrical Review of Aug. 15 devotes considerable space to an analysis of present export trade conditions in England. It is stated that during the present year exports of British electrical goods has been in excess of £500,000 a month, toward which amount European countries contributed only £88,000 worth of purchases. This figure includes countries not directly engaged in war, and in any case it is not greatly in excess of English electrical trade with India alone. Less than 20 per cent of British overseas trade is concerned with Europe and obviously a much smaller proportion with Germany, Austria-Hungary and Russia, the countries which may be regarded as absolutely sealed by the war. The balance of English export trade represents trade with countries far removed from the war, the best customers being India, Japan, Australia, Canada and the South American republics. The distribution of English export trade to all customers is shown by Table III.

Germany has heretofore made a preponderating contribution of English electrical imports. In recent months England received on the average about £275,000 of electrical imports. Of this German imports accounted for £156,000 and Austro-Hungarian for £1,800. France and Belgium contributed between £25,000 and

TABLE III.—SHOWING PRINCIPAL FOREIGN AND COLONIAL ELECTRICAL MARKETS OF GREAT BRITAIN AND AVERAGE MONTHLY VALUES OF ELECTRICAL EXPORTS.

*Europe	£88,000
India	78,000
Australia	74,000
British South African Colonies	45,000
Argentina	45,000
Japan	38,000
Canada	36,000
China and Federated Malay States	27,000
New Zealand	23,000
Brazil	23,000
Remaining Countries of Africa	21,000
Remaining Countries of South America	10.000

*Russia, Germany, Austria-Hungary and Balkan nations, £18,000

£30,000 worth of electrical imports per month. All these competitors in the home market will be seriously affected by the war, but the trade of the United States, which in June exported nearly £60,000 of electrical goods to England, should not be so greatly damaged.

GENERAL ENGLISH TRADE OUTLOOK

MANUFACTURERS EXPECT WAR ULTIMATELY TO RENDER COUNTRY LESS INDUSTRIALLY DEPENDENT UPON CONTINENT

According to *The Electrician* of Aug. 7, the outlook for the electrical trade should become brighter as the first operations of the war are concluded. It is realized that those firms that are now and have been for many years trading in electrical plant, apparatus and materials from the Continent and particularly Central Europe, will have no alternative but to close their doors. Indeed, English inter-trade with the Continent in electrical material, both raw and finished, is said to have already completely ceased. As a result, the minds of British manufacturers have turned toward those outlets of trade which the distant parts of the Empire and other unaffected countries offer. *The Electrician* of Aug. 14 is particularly optimistic in regard to the future of British electrical trade. From inquiries made of the principal electrical manufacturing firms and supply houses, it appears that there has been no unwonted falling-off of trade. It is feared that a few companies will for a period be undermanned, but this is not looked upon as a permanently serious factor. The paper concludes: "The contracting element need feel no uneasiness that there will be any dearth of supplies nor have any doubts that the financial situation will generally favor the continuance of trading. Everything seems to justify the fixing up of a notice in the window of every electrical concern in England —'Business as usual.'"

The general opinion of *The Engineer* is that English manufacturers "must face the difficulties of a temporarily collapsed trade, strong in the conviction that when the war is over their position will be far stronger than it has ever been."

The Electrical Review, in its issue of Aug. 7, states that Canada and the United States may find their financial salvation by reason of the present situation, and the belief is expressed that the future holds such an activity in trade, in metals, in stocks and bonds, as few can remember. The next issue of the paper characterizes as unpatriotic the action of some firms (scarcely any electrical) in issuing circulars broadcast to their clients to the effect that in the future they must have cash with their orders. It is stated with emphasis that no departure should be made from the usual practice with regard to credit accounts unless circumstances arise which render such a move absolutely unavoidable, a contingency at present not anticipated. In concluding, comment is made as follows: "One of the unexpected disclosures effected by the outbreak of the war is the extent to which reliance has been placed by British manufacturers upon supplies of raw material from Germany, as evidenced by the number who have had to close their works for want of it. We trust that the outcome will be the transference of the bulk of this trade to British purchasers of raw material. We believe that the cut-throat competition with which our manufacturers have suffered in the past will be removed, the exploitation of the British dominions and colonies will cease and the large amount of foreign trade will be deferred from the Continent to British workshops."

SOUTH AMERICAN TRADE CONDITIONS

W. J. CLARK EXPLAINS REASONS FOR EUROPEAN INDUSTRIAL SUPREMACY IN SOUTH AMERICA AND FOR POSSIBLE SUCCESS OF UNITED STATES THERE

W. J. Clark, manager of the traction department of the General Electric Company, takes an optimistic view of the ultimate effect of the war upon industrial conditions in this country, but he feels that it will take time to adapt our financial machinery to the new conditions. European financiers have made a diligent study of foreign business for such a long time that Americans cannot expect to learn the art of dealing with South American countries, especially, in a few months. In his opinion a vital feature in the European industrial achievements abroad has been the attention given to the financial standing of individual foreign customers. The status of each as a creditor is carefully studied and suitable terms are made for him. Credits up to two years are sometimes allowed with a reasonable interest rate which can be discounted at home, making a profitable transaction for seller as well as purchaser. Belgium, which has been so far the center of conflict in the present war, has played an important part in the financing of foreign undertakings. It has been to a considerable extent a clearing house for them due to favorable laws, to the supposedly neutral character of the country and to the excellent Belgium consular service. Corporations in other countries invested through Belgium corporations somewhat as though they were holding companies. The capital placed thus outside of Belgium in public utilities of various kinds is at least $1,000,000,000. There are also vast sums invested directly by French, German and other financiers. In South America the public utilities, with the exception of the Pearson, Grace and minor interests, are financed in Europe principally, directly or indirectly, from Germany. To offset the conditions outlined, Mr. Clark believes that, aside from the temporary and possibly permanent conditions produced by the present war, the principal advantages possessed by American manufacturers lie in the quality of their products and the ability of their selling forces. That our manufacturers are beginning to appreciate their opportunity is shown by the activity of the United States Steel Corporation and a few other enterprising organizations.

The General Electric Company does much of its South American business through its London office, opened fourteen years or more ago, largely to handle foreign business. A very large business is done here because London is the natural center for South American trading. The company also controls the South American General Electric Company with headquarters at Buenos Aires and it has regular office headquarters at Rio de Janeiro. In addition a large business is handled by W. R. Grace & Company in the West and Southwest, and by Amsinck & Company in the North.

In discussing the probable effects of the war upon financial and industrial conditions Mr. Clark stated that he expects some small immediate benefits and larger ultimate ones. At first there should be an increase in the demand for small supplies for which the purchaser can pay directly. The present plants must be kept up and supplies will be required at once. Ultimately foreign projects will have to be partially, and possibly largely, financed from America. Europe up to this time has largely financed all foreign undertakings, but America must shoulder part of the burden because European money will be needed at home. As foreign ownership influences trade to a large extent it follows that, as fast as American money is invested abroad, American trade will follow it. South America has little money of its own, hence must depend upon the outside world for capital. The conditions for investment, moreover, are favorable and they are constantly becoming less so in this country, at least so far as public utilities are concerned.

In Mr. Clark's opinion the close of the war will be followed by an influx of very desirable immigrants who will flee from the burdens which inevitably follow a great war. South America will share in this benefit as it did fifty years ago when some of the present prosperous Irish and other families settled there, particularly in the River Plate country. The reaction of the war will probably also be seen in the increased costs of manufacturing in Europe, both in labor and supplies, through high taxes and shortages, due to destruction and non-production. These will act as a protection to American industries, enabling them to offset the results of tariff reductions.

INSTRUCTIONS TO COMMERCIAL TRAVELERS IN SOUTH AMERICA

E. F. COLYER EMPHASIZES NEED OF KNOWLEDGE OF NATIVE LANGUAGE, OF PERSONAL CONTACT WITH CUSTOMER AND OF PROPER SEASONAL TRAVELING

E. F. Colyer, in charge of the Latin-American section of the foreign department of the General Electric Company, has had much experience in Central America and South America. In discussing export trade matters with a representative of the ELECTRIC RAILWAY JOURNAL, he said that no commercial traveler who went to either Central America or South America could do much if he did not know the language spoken in the country visited. In all countries except Brazil, where Portuguese is spoken, and British, French and Dutch Guiana, it is necessary to talk Spanish. Although some of the plants are owned by English or Americans, the miscellaneous trade, except in the large cities, is principally in the hands of native firms. With these a foreigner, who had to talk through an interpreter, could make very little progress, Mr. Colyer believes. This, of course, applies to travelers who are trying to make actual sales. If a representative of an American manufacturer goes to the country merely in order to get information concerning the outlook for his goods, it is not so imperative that he speak the language. It will be found that many of the plants and stores in Central American countries have connections with commission houses in New York and New Orleans.

In offering goods to residents of the Central and South American countries it is most desirable, Mr. Colyer stated, to have letters of introduction in order that a friendly relation may be established before actual business is attempted. As the banks of this country do not often have correspondents there, they are not likely to be of much assistance to commercial travelers. If it is possible to get a letter of introduction to a resident banker or to establish a business connection with him that is an advantage. In all cases the first man to be seen is the American consul. These men are always glad to assist anyone who is on a business trip, and frequently they are able to give much information that is of value. Correspondence between a company and a possible consumer is, of course, a step toward a personal introduction that will be found to be a help.

Mr. Colyer emphasized the fact that much of the business with the greater part of Central and South America is likely to be small in amount and that some time is required to develop the market. He figures the traveling expense of a salesman in Central or South American countries at about $5,000 a year. If a salesman were to attempt to cover the entire field he would find the territory so large that he might easily become discouraged. Business is not transacted in accordance with the practices that prevail here. Often a salesman will not receive a single order until he has been on the ground for weeks.

Mr. Colyer said that with the possible exception of Guatemala, which is more nearly a market for European countries, the Central American countries patronize mainly the manufacturers of this country. Between the commission and jobbing houses and local representatives of American firms, Central America is now well covered by American manufacturers.

In regard to the time of the year when trips should be made by representatives of manufacturers, Mr. Colyer said that it varied with the section visited, but that it was desirable to avoid the rainy season. Clothes suitable for the tropics should be taken, with a light overcoat for the altitudes. On account of the condition of the rivers in Colombia, it is possible to get into the interior of that country readily during only two seasons of the year.

The question of granting credit, Mr. Colyer believes, is not radically different in Central and South America from other countries. A good deal of misinformation has been published about the general necessity of very long credits, which are not the invariable rule. In some lines extended credits must be given, while in others it would be poor business policy. The practice in different markets and in different lines varies widely.

GOVERNMENT MOVES TO SECURE FOREIGN TRADE

AMERICAN AGENTS TO WORK WITH MANUFACTURERS IN STUDYING TRADE CONDITIONS IN SOUTH AMERICA AND THE FAR EAST

An appropriation of $50,000 for promoting the commerce in Central and South America, which for the first time is now available to the Bureau of Foreign and Domestic Commerce for the current fiscal year, is to be used promptly to reinforce the existing service for the development of Latin-American trade, according to the latest *Daily Consular and Trade Report.* Much work has already been done in this field in the line of reports covering current branches of commerce, but now a number of new phases of the trade will be intensively studied by special government agents. Agents will begin field investigations as soon as they can reach their several districts in Central and South America.

The appropriation for commercial attachés of the Bureau of Foreign and Domestic Commerce is also now available and the appointees of this class of trade promotion, those of the government for Rio de Janeiro, Buenos Aires, Santiago and Lima, will be promptly dispatched to their posts as soon as selected.

B. Joachim, special commercial representative of the Department of Commerce, who is about to conduct an investigation in South America in furtherance of American export trade, says that the existing war represents the greatest opportunity American manufacturers and exporters have ever had to capture South American markets. Mr. Joachim can for a time be reached through the New York City branch of the Bureau of Foreign and Domestic Commerce. Ralph M. Odell, another commercial agent, sails from San Francisco for Corea on Aug. 29. Mr. Odell is to spend two years investigating Oriental markets in the interests of American exporters. He will devote much of his time to the study of the markets of India as a source for American exports and will also look into the trade conditions and requirements in China and the Straits Settlements.

POINTS REQUIRING CAUTION IN INSTITUTING SOUTH AMERICAN TRADE

G. H. CHARLS MAKES PLEA FOR PROPER CONSIDERATION OF SOUTH AMERICAN TRADE REQUIREMENTS

In an interview with G. H. Charls, assistant secretary and sales manager American Rolling Mills Company, it was stated to a representative of the ELECTRIC RAILWAY JOURNAL that the chief words in connection with the possibilities of increasing United States trade with South America are "utmost caution." American manufacturers thoroughly familiar with the conditions that have prevailed during the past year in all South American countries and even the most representative South American merchants are proceeding cautiously because of the financial readjustment which is occurring there.

South America has relied upon foreign capital to finance practically all of its big undertakings. With the beginning of the Balkan war a money tightness became prevalent. Land speculation drove the price of many properties to twice their real value. Money borrowed from Europe paid for these lands. To-day many owners of fine camps and plantations find themselves in the position of being able to earn just sufficient profit to pay the interest on their loans. Misfortunes in crops have embarrassed these owners seriously. The present war has made it impossible for South American countries to float their loans abroad, and unless the bankers and capitalists of the United States go to their relief dull times will continue to prevail.

Too many, in Mr. Charls's opinion, are aroused to action by the fact that England, Germany and France, who formerly controlled the lion's share of South American business, are now at war. American manufacturers must keep in mind that these same countries consumed a proportional amount of the exported products of all South American nations. These conditions will not tend to lighten the financial situation which was so serious before the European war began. The merchants of Brazil, Argentina and Chile are not accepting orders without full information on the financial standing of their customers, and it will be well for United States manufacturers to follow their example.

According to Mr. Charls, two very important steps must be taken by North Americans to secure a permanent, profitable business relation with the nations south of us. The first is to secure proper shipping facilities. Some important and successful efforts to accomplish this task are now in progress, but all need the hearty support of every manufacturer interested in this field. The second is an awakening of United States bankers and capitalists to the splendid opportunities for profitable investment offered them in South America.

Mr. Charls expressed his regret that one of the large enterprising American railway firms operating in Argentina and Brazil was forced a year ago to appeal to English and French capitalists. The European capitalists, in cases of this kind, require that European products be purchased. Many of the largest systems of railways, rubber plantations, nitrate fields, public utilities, mines, etc., are financed by Europeans on the above basis. Therefore, notwithstanding the recognized superiority of United States products, American manufacturers lose the order. The chairman of one of the largest railway systems in Brazil, whose headquarters are in London, said: "If we intended purchasing $100,000 of material we would dislike very much for $1 of this business to be purchased in the United States if it could be produced in Europe." Too much emphasis cannot be laid on the danger of this impediment to the success of the manufacturers of the United States endeavoring to secure a successful foothold in South America.

Mr. Charls stated that American firms may either improve or endanger their future relations with South American countries by their actions and methods of doing business at this time. In order to gain their confidence manufacturers in this country must send them just what they order to the last detail, do business with them as they are accustomed to doing it, and devote every effort to please and win their respect. This can be accomplished only in one way, said Mr. Charls. Send experienced, tactful representatives speaking fluently the language of the country they visit, to study conditions, to make acquaintances, and, most important, to ascertain the exact requirements of the trade. Then these requirements should be filled without one hint of substitution. By this procedure due caution will be observed, and financial risks minimized on immediate business.

CITIES IN SOUTH AMERICA

The following table gives the names of the cities in South America with a population of 50,000 or more, according to the latest available census reports.

TABLE SHOWING POPULATION OF LARGEST CITIES IN SOUTH AMERICA

Buenos Aires	Argentina	1,331,000
Rio de Janeiro	Brazil	1,000,000
Santiago	Chile	400,000
Sao Paulo	Brazil	400,000
Bahia	Brazil	350,000
Montevideo	Uruguay	252,000
Pernambuco (Recife)	Brazil	150,000
Bogota	Columbia	150,000
Belem (Para)	Brazil	150,000
Rosario	Argentina	150,000
Valparaiso	Chile	150,000
Lima	Peru	140,000
Porto Alegre	Brazil	100,000
La Plata	Argentina	80,000
Quito	Ecuador	80,000
La Paz	Bolivia	80,000
Guayaquil	Ecuador	75,000
Caracas	Venezuela	72,000
Cordoba	Argentina	59,000
Ouro Preto	Brazil	60,000
Tucuman	Argentina	55,000
Georgetown	British Guiana	53,000
Concepcion	Chile	51,000
Mendoza	Argentina	51,000
Medellin	Colombia	50,000
Manaos	Brazil	50,000
Fortaleza	Brazil	50,000

The city treasury of Newark, N. J., has received from the Public Service Railway $173,976.99, which represents 5 per cent of the gross earnings from passenger traffic in the city during the year ending April 31. The company was obliged to pay this as practically a franchise tax in accordance with an old ordinance authorizing a change from horse-car to electricity. The amount is about $5,000 less than that paid the city for a similar purpose last year. Various reasons are assigned for the decrease, one of which is the falling off of traffic during the two big storms of the winter.

Statistics of Electric Railways for 1913

Following its previous practice the ELECTRIC RAILWAY JOURNAL publishes herewith a compilation of statistics of electric railway companies based on the returns given in the *McGraw Electric Railway Manual.* The statistics are compiled from the 1914 edition of the *McGraw Electric Railway Manual* and therefore represent the condition of the industry at the end of the year 1913. As in previous similar compilations the miles of track, the number of cars and the authorized and outstanding capital stock and funded debt are given. The same division as to States and groups of States that has been shown in earlier tables has been

STATE	NUMBER OF RY. COMPANIES	MILES OF TRACK	CARS	CAPITAL STOCK		FUNDED DEBT		TOTAL STOCKS AND BONDS

followed in this case. As the returns for the small companies were included in the 1914 edition of the *McGraw Electric Railway Manual* the compilation is based more nearly on actual figures from the companies and to a smaller degree on estimates than has been the case for several years past. The returns are mainly taken by companies as no systematic attempt has been made to segregate capitalization applicable only to the electric railway in cases where companies operate two or more classes of utilities.

Making A Park Pay

BY W. H. BOYCE, SUPERINTENDENT THE BEAVER VALLEY TRACTION COMPANY, NEW BRIGHTON, PA.

Junction Park until 1913 had been an amusement park on the lines of our company, the Beaver Valley Traction Company. During 1913 we made a contract with the Beaver County Agricultural Association, which had recently been organized, whereby we furnished the grounds and constructed a race track in Junction Park, giving the association a ten-year lease on the grounds. The association in turn built a grandstand with a seating capacity of 3000 and constructed stables, poultry-house, cattle pens and other buildings necessary for the conduct of a county fair.

Although the year 1914 saw the first fair held in Beaver County since 1902 and we experienced such bad weather during the first days of the fair that but two days of racing were possible, the fair was very well attended. The association had about 7000 paid admissions on Thursday, 8500 on Friday and 14,500 on Saturday.

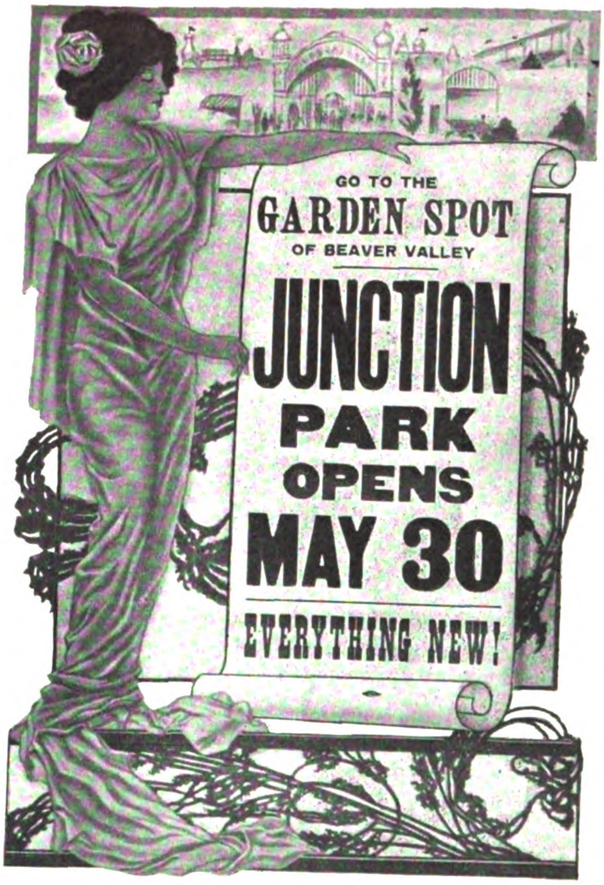
DODGER WITH IMITATION OF BANK NOTE ON BACK

In rearranging the grounds and constructing the race track we expended approximately $11,000. From our fair week revenue, as compared with the same week in previous years, after deducting all extra operating expenses, such as trainmen's wages, policemen's wages and extra coal consumed, we found that we had earned $1,800, or a little more than 16 per cent on our investment. We also have the promise of a very good fair at Junction Park this September.

In addition to the crowd that the race track brings to the fair, we sought extra business this year by advertising and by employing a park solicitor for a month before Decoration Day. As a result we booked about forty picnics where heretofore we did not exceed more than eight to ten picnics during the season because most of the organizations throughout the Beaver Valley had previously gone to out-of-town resorts. This year we could offer the use of a very fine half-mile track for motorcycle, automobile, bicycle and miscellaneous athletic races. This improvement and others, like the planting of many large shade trees, was a strong inducement in attracting these organizations to us.

Beside the picnics we have had field meets and professional automobile races with such drivers as Eddie Hearne and Louis Disbrow. Altogether, the installation of the race track has proved to be a very profitable investment. Junction Park is located just across the street from our office, shop, carhouse and power station and is about ten minutes run from the Pittsburgh & Lake Erie station (New York Central Lines) at Beaver and five minutes from the Pennsylvania station at New Brighton, so that it is a very desirable spot for a fair ground.

Display window cards announcing the opening of the park were placed in most of the store windows throughout Beaver Valley and in our cars. One form of novelty advertising was the distribution of a pen contained in an envelope, with the appropriate wording to "take a pointer" as to Junction Park; another was imitation money with lettering on one side, as reproduced; and a third was a box of safety matches with picnic and safety advertising. In addition to this, one-sheet posters of the form illustrated were placed in store windows and similar eight-sheet posters were used on billboards.



TYPICAL POSTER ADVERTISING JUNCTION PARK

When our traffic representative was about to close up with a picnic committee which was apparently lagging and undecided, he would send them a pair of 10-cent glasses, secured at a 5 and 10-cent store, with a letter stating that he hoped these glasses would aid them to see their way clear to attend Junction Park.

Provision has been made for the electrification of the Montreal (Que.) Harbor Railways. The cost is estimated at $282,674, with $300,000 for equipment. This year the actual trackage of the electrification will be extended to Pointe aux Trembles. The ultimate terminus of the railway system is Bout de l'Ile, which it is expected will be reached next year. On the south shore 8 miles of electric railway track will be laid.

crease in the demand for small supplies for which the purchaser can pay directly. The present plants must be kept up and supplies will be required at once. Ultimately foreign projects will have to be partially, and possibly largely, financed from America. Europe up to this time has largely financed all foreign undertakings, but America must shoulder part of the burden because European money will be needed at home. As foreign ownership influences trade to a large extent it follows that, as fast as American money is invested abroad, American trade will follow it. South America has little money of its own, hence must depend upon the outside world for capital. The conditions for investment, moreover, are favorable and they are constantly becoming less so in this country, at least so far as public utilities are concerned.

In Mr. Clark's opinion the close of the war will be followed by an influx of very desirable immigrants who will flee from the burdens which inevitably follow a great war. South America will share in this benefit as it did fifty years ago when some of the present prosperous Irish and other families settled there, particularly in the River Plate country. The reaction of the war will probably also be seen in the increased costs of manufacturing in Europe, both in labor and supplies, through high taxes and shortages, due to destruction and non-production. These will act as a protection to American industries, enabling them to offset the results of tariff reductions.

INSTRUCTIONS TO COMMERCIAL TRAVELERS IN SOUTH AMERICA

E. F. COLYER EMPHASIZES NEED OF KNOWLEDGE OF NATIVE LANGUAGE, OF PERSONAL CONTACT WITH CUSTOMER AND OF PROPER SEASONAL TRAVELING

E. F. Colyer, in charge of the Latin-American section of the foreign department of the General Electric Company, has had much experience in Central America and South America. In discussing export trade matters with a representative of the ELECTRIC RAILWAY JOURNAL, he said that no commercial traveler who went to either Central America or South America could do much if he did not know the language spoken in the country visited. In all countries except Brazil, where Portuguese is spoken, and British, French and Dutch Guiana, it is necessary to talk Spanish. Although some of the plants are owned by English or Americans, the miscellaneous trade, except in the large cities, is principally in the hands of native firms. With these a foreigner, who had to talk through an interpreter, could make very little progress, Mr. Colyer believes. This, of course, applies to travelers who are trying to make actual sales. If a representative of an American manufacturer goes to the country merely in order to get information concerning the outlook for his goods, it is not so imperative that he speak the language. It will be found that many of the plants and stores in Central American countries have connections with commission houses in New York and New Orleans.

In offering goods to residents of the Central and South American countries it is most desirable, Mr. Colyer stated, to have letters of introduction in order that a friendly relation may be established before actual business is attempted. As the banks of this country do not often have correspondents there, they are not likely to be of much assistance to commercial travelers. If it is possible to get a letter of introduction to a resident banker or to establish a business connection with him that is an advantage. In all cases the first man to be seen is the American consul. These men are always glad to assist anyone who is on a business trip, and frequently they are able to give much information that is of value. Correspondence between a company and a possible consumer is, of course, a step toward a personal introduction that will be found to be a help.

Mr. Colyer emphasized the fact that much of the business with the greater part of Central and South America is likely to be small in amount and that some time is required to develop the market. He figures the traveling expense of a salesman in Central or South American countries at about $5,000 a year. If a salesman were to attempt to cover the entire field he would find the territory so large that he might easily become discouraged. Business is not transacted in accordance with the practices that prevail here. Often a salesman will not receive a single order until he has been on the ground for weeks.

Mr. Colyer said that with the possible exception of Guatemala, which is more nearly a market for European countries, the Central American countries patronize mainly the manufacturers of this country. Between the commission and jobbing houses and local representatives of American firms, Central America is now well covered by American manufacturers.

In regard to the time of the year when trips should be made by representatives of manufacturers, Mr. Colyer said that it varied with the section visited, but that it was desirable to avoid the rainy season. Clothes suitable for the tropics should be taken, with a light overcoat for the altitudes. On account of the condition of the rivers in Colombia, it is possible to get into the interior of that country readily during only two seasons of the year.

The question of granting credit, Mr. Colyer believes, is not radically different in Central and South America from other countries. A good deal of misinformation has been published about the general necessity of very long credits, which are not the invariable rule. In some lines extended credits must be given, while in others it would be poor business policy. The practice in different markets and in different lines varies widely.

GOVERNMENT MOVES TO SECURE FOREIGN TRADE

AMERICAN AGENTS TO WORK WITH MANUFACTURERS IN STUDYING TRADE CONDITIONS IN SOUTH AMERICA AND THE FAR EAST

An appropriation of $50,000 for promoting the commerce in Central and South America, which for the first time is now available to the Bureau of Foreign and Domestic Commerce for the current fiscal year, is to be used promptly to reinforce the existing service for the development of Latin-American trade, according to the latest *Daily Consular and Trade Report.* Much work has already been done in this field in the line of reports covering current branches of commerce, but now a number of new phases of the trade will be intensively studied by special government agents. Agents will begin field investigations as soon as they can reach their several districts in Central and South America.

The appropriation for commercial attachés of the Bureau of Foreign and Domestic Commerce is also now available and the appointees of this class of trade promotion, those of the government for Rio de Janeiro, Buenos Aires, Santiago and Lima, will be promptly dispatched to their posts as soon as selected.

B. Joachim, special commercial representative of the Department of Commerce, who is about to conduct an investigation in South America in furtherance of American export trade, says that the existing war represents the greatest opportunity American manufacturers and exporters have ever had to capture South American markets. Mr. Joachim can for a time be reached through the New York City branch of the Bureau of Foreign and Domestic Commerce. Ralph M. Odell, another commercial agent, sails from San Francisco for Corea on Aug. 29. Mr. Odell is to spend two years investigating Oriental markets in the interests of American exporters. He will devote much of his time to the study of the markets of India as a source for American exports and will also look into the trade conditions and requirements in China and the Straits Settlements.

POINTS REQUIRING CAUTION IN INSTITUTING SOUTH AMERICAN TRADE

G. H. CHARLS MAKES PLEA FOR PROPER CONSIDERATION OF SOUTH AMERICAN TRADE REQUIREMENTS

In an interview with G. H. Charls, assistant secretary and sales manager American Rolling Mills Company, it was stated to a representative of the ELECTRIC RAILWAY JOURNAL that the chief words in connection with the possibilities of increasing United States trade with South America are "utmost caution." American manufacturers thoroughly familiar with the conditions that have prevailed during the past year in all South American countries and even the most representative South American merchants are proceeding cautiously because of the financial readjustment which is occurring there.

South America has relied upon foreign capital to finance practically all of its big undertakings. With the beginning of the Balkan war a money tightness became prevalent. Land speculation drove the price of many properties to twice their real value. Money borrowed from Europe paid for these lands. To-day many owners of fine camps and plantations find themselves in the position of being able to earn just sufficient profit to pay the interest on their loans. Misfortunes in crops have embarrassed these owners seriously. The present war has made it impossible for South American countries to float their loans abroad, and unless the bankers and capitalists of the United States go to their relief dull times will continue to prevail.

Too many, in Mr. Charls's opinion, are aroused to action by the fact that England, Germany and France, who formerly controlled the lion's share of South American business, are now at war. American manufacturers must keep in mind that these same countries consumed a proportional amount of the exported products of all South American nations. These conditions will not tend to lighten the financial situation which was so serious before the European war began. The merchants of Brazil, Argentina and Chile are not accepting orders without full information on the financial standing of their customers, and it will be well for United States manufacturers to follow their example.

According to Mr. Charls, two very important steps must be taken by North Americans to secure a permanent, profitable business relation with the nations south of us. The first is to secure proper shipping facilities. Some important and successful efforts to accomplish this task are now in progress, but all need the hearty support of every manufacturer interested in this field. The second is an awakening of United States bankers and capitalists to the splendid opportunities for profitable investment offered them in South America.

Mr. Charls expressed his regret that one of the large enterprising American railway firms operating in Argentina and Brazil was forced a year ago to appeal to English and French capitalists. The European capitalists, in cases of this kind, require that European products be purchased. Many of the largest systems of railways, rubber plantations, nitrate fields, public utilities, mines, etc., are financed by Europeans on the above basis. Therefore, notwithstanding the recognized superiority of United States products, American manufacturers lose the order. The chairman of one of the largest railway systems in Brazil, whose headquarters are in London, said: "If we intended purchasing $100,000 of material we would dislike very much for $1 of this business to be purchased in the United States if it could be produced in Europe." Too much emphasis cannot be laid on the danger of this impediment to the success of the manufacturers of the United States endeavoring to secure a successful foothold in South America.

Mr. Charls stated that American firms may either improve or endanger their future relations with South American countries by their actions and methods of doing business at this time. In order to gain their confidence manufacturers in this country must send them just what they order to the last detail, do business with them as they are accustomed to doing it, and devote every effort to please and win their respect. This can be accomplished only in one way, said Mr. Charls. Send experienced, tactful representatives speaking fluently the language of the country they visit, to study conditions, to make acquaintances, and, most important, to ascertain the exact requirements of the trade. Then these requirements should be filled without one hint of substitution. By this procedure due caution will be observed, and financial risks minimized on immediate business.

CITIES IN SOUTH AMERICA

The following table gives the names of the cities in South America with a population of 50,000 or more, according to the latest available census reports.

TABLE SHOWING POPULATION OF LARGEST CITIES IN SOUTH AMERICA

Buenos Aires	Argentina	1,331,000
Rio de Janeiro	Brazil	1,000,000
Santiago	Chile	400,000
Sao Paulo	Brazil	400,000
Bahia	Brazil	350,000
Montevideo	Uruguay	252,000
Pernambuco (Recife)	Brazil	150,000
Bogota	Columbia	150,000
Belem (Para)	Brazil	150,000
Rosario	Argentina	150,000
Valparaiso	Chile	150,000
Lima	Peru	140,000
Porto Alegre	Brazil	100,000
La Plata	Argentina	80,000
Quito	Ecuador	80,000
La Paz	Bolivia	80,000
Guayaquil	Ecuador	75,000
Caracas	Venezuela	72,000
Cordoba	Argentina	59,000
Ouro Preto	Brazil	60,000
Tucuman	Argentina	55,000
Georgetown	British Guiana	53,000
Concepcion	Chile	51,000
Mendoza	Argentina	51,000
Medellin	Colombia	50,000
Manaos	Brazil	50,000
Fortaleza	Brazil	50,000

The city treasury of Newark, N. J., has received from the Public Service Railway $173,976.99, which represents 5 per cent of the gross earnings from passenger traffic in the city during the year ending April 31. The company was obliged to pay this as practically a franchise tax in accordance with an old ordinance authorizing a change from horse-car to electricity. The amount is about $5,000 less than that paid the city for a similar purpose last year. Various reasons are assigned for the decrease, one of which is the falling off of traffic during the two big storms of the winter.

Statistics of Electric Railways for 1913

Following its previous practice the ELECTRIC RAILWAY JOURNAL publishes herewith a compilation of statistics of electric railway companies based on the returns given in the *McGraw Electric Railway Manual.* The statistics are compiled from the 1914 edition of the *McGraw Electric Railway Manual* and therefore represent the condition of the industry at the end of the year 1913. As in previous similar compilations the miles of track, the number of cars and the authorized and outstanding capital stock and funded debt are given. The same division as to States and groups of States that has been shown in earlier tables has been

followed in this case. As the returns for the small companies were included in the 1914 edition of the *McGraw Electric Railway Manual* the compilation is based more nearly on actual figures from the companies and to a smaller degree on estimates than has been the case for several years past. The returns are mainly taken by companies as no systematic attempt has been made to segregate capitalization applicable only to the electric railway in cases where companies operate two or more classes of utilities.

Making A Park Pay

BY W. H. BOYCE, SUPERINTENDENT THE BEAVER VALLEY TRACTION COMPANY, NEW BRIGHTON, PA.

Junction Park until 1913 had been an amusement park on the lines of our company, the Beaver Valley Traction Company. During 1913 we made a contract with the Beaver County Agricultural Association, which had recently been organized, whereby we furnished the grounds and constructed a race track in Junction Park, giving the association a ten-year lease on the grounds. The association in turn built a grandstand with a seating capacity of 3000 and constructed stables, poultry-house, cattle pens and other buildings necessary for the conduct of a county fair.

Although the year 1914 saw the first fair held in Beaver County since 1902 and we experienced such bad weather during the first days of the fair that but two days of racing were possible, the fair was very well attended. The association had about 7000 paid admissions on Thursday, 8500 on Friday and 14,500 on Saturday.

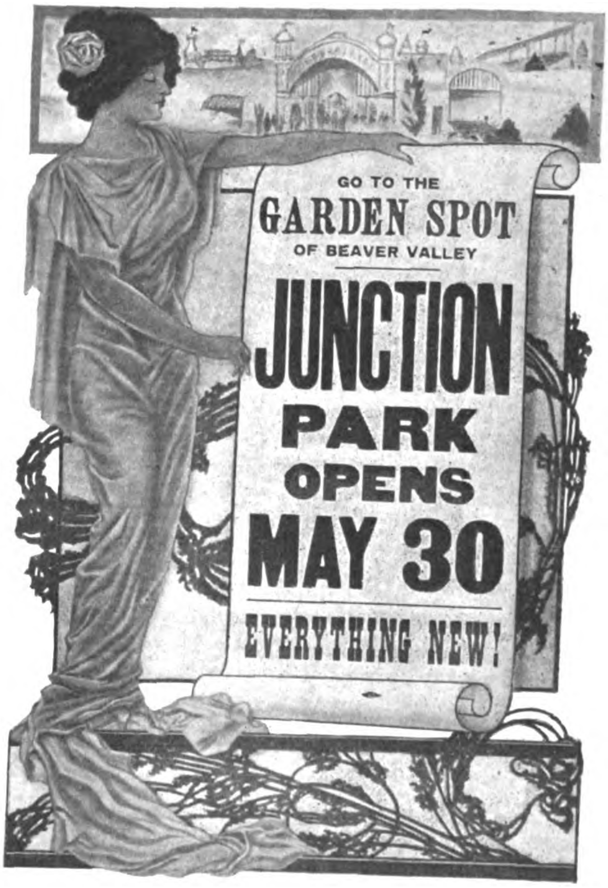
DODGER WITH IMITATION OF BANK NOTE ON BACK

In rearranging the grounds and constructing the race track we expended approximately $11,000. From our fair week revenue, as compared with the same week in previous years, after deducting all extra operating expenses, such as trainmen's wages, policemen's wages and extra coal consumed, we found that we had earned $1,800, or a little more than 16 per cent on our investment. We also have the promise of a very good fair at Junction Park this September.

In addition to the crowd that the race track brings to the fair, we sought extra business this year by advertising and by employing a park solicitor for a month before Decoration Day. As a result we booked about forty picnics where heretofore we did not exceed more than eight to ten picnics during the season because most of the organizations throughout the Beaver Valley had previously gone to out-of-town resorts. This year we could offer the use of a very fine half-mile track for motorcycle, automobile, bicycle and miscellaneous athletic races. This improvement and others, like the planting of many large shade trees, was a strong inducement in attracting these organizations to us.

Beside the picnics we have had field meets and professional automobile races with such drivers as Eddie Hearne and Louis Disbrow. Altogether, the installation of the race track has proved to be a very profitable investment. Junction Park is located just across the street from our office, shop, carhouse and power station and is about ten minutes run from the Pittsburgh & Lake Erie station (New York Central Lines) at Beaver and five minutes from the Pennsylvania station at New Brighton, so that it is a very desirable spot for a fair ground.

Display window cards announcing the opening of the park were placed in most of the store windows throughout Beaver Valley and in our cars. One form of novelty advertising was the distribution of a pen contained in an envelope, with the appropriate wording to "take a pointer" as to Junction Park; another was imitation money with lettering on one side, as reproduced; and a third was a box of safety matches with picnic and safety advertising. In addition to this, one-sheet posters of the form illustrated were placed in store windows and similar eight-sheet posters were used on billboards.



TYPICAL POSTER ADVERTISING JUNCTION PARK

When our traffic representative was about to close up with a picnic committee which was apparently lagging and undecided, he would send them a pair of 10-cent glasses, secured at a 5 and 10-cent store, with a letter stating that he hoped these glasses would aid them to see their way clear to attend Junction Park.

Provision has been made for the electrification of the Montreal (Que.) Harbor Railways. The cost is estimated at $282,674, with $300,000 for equipment. This year the actual trackage of the electrification will be extended to Pointe aux Trembles. The ultimate terminus of the railway system is Bout de l'Ile, which it is expected will be reached next year. On the south shore 8 miles of electric railway track will be laid.

COMMUNICATIONS

Futility of Heavy Plates for Side Sheathing

PHILADELPHIA, PA., Aug. 19, 1914.

To the Editors:

Referring to your editorial on steel sheathing for car siding in the ELECTRIC RAILWAY JOURNAL of Aug. 15, I append some computations showing the strength and weights of various car sides, as shown in the accompanying cut, which may be of interest to your readers.

Assumed constructions of car siding

Case *A*. The girder siding here consists of a belt rail 3½-in. x ⅝-in. bar, the side sheet of 30-in. x ⅛-in plate and a side sill of 4-in. x 4-in. x ⅜-in. angle. This section is similar to that used in a great many instances, the belt rail being made ⅝ in. thick to facilitate shop work, it being easier to maintain a section of this weight in alignment than with a lighter section. The size of the bottom angle in girders of this kind is determined by the amount of material to be suspended from it and by the construction of the bolsters and other cross members of the car.

Case *B*. The second case is computed on the same section as before except that in determining the center of gravity and the moment of inertia, the side sheet is neglected entirely. For the sake of comparison the belt rail and side sill are made the same as in the first case.

Case *C*. The third case considers a car using the steel construction similar to that in the two foregoing cases with the addition of a side plate or top plate, consisting in this case of an angle. This top plate angle is 3½-in. x 2½-in. x ¼-in. angle with a 3½-in. leg vertical. The belt rail consists of a 3-in. x ¼-in. bar, the side sheet of a 30-in. x ⅛-in. plate and side sill of 4-in. x 4-in. x 5/16-in. angle. The total depth of the girder is 93 in., as shown, which is possibly slightly in excess of the depth of the girder for the average city car but is about correct for cars used in interurban service.

Case *D*. In the fourth case the same girder is considered as in the third case, with the exception that the side sheet is omitted from the computation.

Moments of inertia and section moduli

Case *A*. This computation, using a side plate, gives a total moment of inertia of 1208.9 and a fairly well balanced section, the section modulus at the top being 74.58 and the section modulus at the bottom 87.67.

Case *B*. In the second case, disregarding the side sheet, we get a total moment of inertia of 919.8 and a section modulus at the top and bottom respectively of 53.7 and 71.4.

Case *C*. In this case, using a top plate, we get a total moment of inertia of 8682, the section modulus at the top and bottom respectively of 129.6 and 334. This section takes into consideration the side sheet.

Case *D*. In the fourth case, by disregarding the side sheet, we get a total moment of inertia of 7444 and a section modulus at top and bottom respectively of 126.2 and 219. It is interesting to note in this section that the neutral axis lies above the belt rail, making the belt rail a tension member and allowing the use of a light belt rail, which has been figured.

Stresses and weights

In computing the stresses in the various types, I have assumed arbitrarily an unbalanced moment of 800,000 lb.-in. This is about the average figure for city cars with prepayment platforms. The stresses in the beam as computed in the first case are 10,700 lb. in compression and 9100 lb. in tension, while the stress as computed in the second case, neglecting the side sheet, runs 14,800 lb. in compression and 11,200 lb. in tension.

With the beam as computed in Cases *C* and *D* we find in Case *C* a stress of 6150 lb. compression and 2390 lb. tension, and as figured in Case *D*, again neglecting the side sheet, we get a stress of 6330 lb. compression and 3650 lb. in tension.

It will be noticed that the increase in stress due to the omission of the side sheet is very much less in Cases *C* and *D* than in Cases *A* and *B*.

The weights of the girders are as follows:

In Case *A*, 30.84 lb. per lineal foot.
In Case *B*, 24.04 lb. per lineal foot.
In Case *C*, 30.1 lb. per lineal foot.
In Case *D*, 22.88 lb. per lineal foot.

In Cases *B* and *D*, in computing the weight, a 1/16-in. sheathing was added for weight but was not considered in computing the strength.

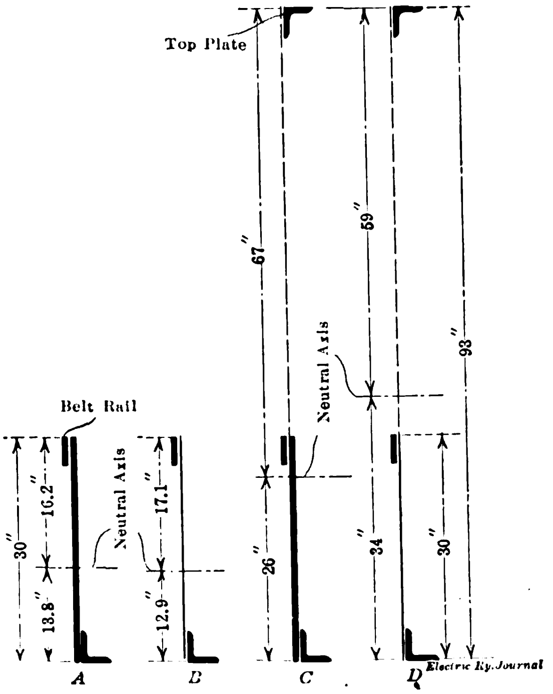


DIAGRAM SHOWING CONSTRUCTION OF FOUR HYPOTHETICAL CASES

The maximum stress for each of these cases is as follows:

Case *A*, 10,700 lb. compression.
Case *B*, 14,800 lb. compression.
Case *C*, 6,150 lb. compression.
Case *D*, 6,330 lb. compression.

Discussion

In making these computations it has been assumed that the posts were applied in the car in such a manner as to prevent buckling of the web due to shear. This is easily accomplished in the average electric car where the post spacing runs from 2 ft. 6 in. to 2 ft. 8 in. centers. Of course, where a girder of the kind considered in Cases *C* and *D* is used, the posts should be of steel, preferably with tee section on account of the great strength for weight and its adaptability to the construction in riveting. In Cases *A* and *B* where the stress in the girder runs high, the shear in the web may be taken care of by angles on each side of the posts where a wooden post is used.

As for the steel sheet, it is hardly necessary to consider it in beam action as it has been considered in Cases *A* and *C* because the sections of the belt rail and sill can easily be made in the average electric car so that the sheet need not be considered at all. Therefore it may be readily seen that where the heavier sheathing is used, sufficient strength is not gained to offset the increase in weight.

A comparison of Cases *A* and *D* gives a good example of what can be accomplished by the use of a top plate, the total difference in weight being approximately 8 lb. per lineal foot, or 480 lb. weight in a car 30 ft. long over the corner posts. Of course, there will be a slight increase in this weight from this figure due to the fact that in any construction of this kind, the posts must be fastened thoroughly at the side sill, belt rail and top plate by means of gussets or otherwise to prevent any loosening of the joints and to develop the full strength of the posts. These connections have not been considered in this calculation, but their weight will be a very small factor in the total and will hardly decrease the total saving in weight by the use of a top plate and 1/16-in. sheathing.

It should be noted that by eliminating the sheathing in computing the strength of the girders it becomes possible to make the side sheet of very light material and in short sections running only between posts or in panels of say two posts each. Then in case of any damage to the side of the car by wagon tongues or accidents of any kind, the sheathing may be easily removed and replaced without disturbing the girder or getting the car out of alignment.

The computations upon which these comparisons were made were accurate in the main but were not carefully carried out to the right of the decimal point. However, I think the comparison thoroughly demonstrates the point brought out in your editorial. Indeed, I believe within the next few years that you will see the light side sheathing come to its own, as I have been told there are electric cars running in England on which aluminum side sheets have been used for effecting reduction in weight. CHARLES J. MCPHERSON.

[The calculations by which the above results were determined accompanied Mr. McPherson's communication. Unfortunately lack of space prohibits their publication, but they are available for anyone who wishes to ascertain in detail how the writer arrived at his conclusions.—EDS.]

CHICAGO, Aug. 21, 1914.

To the Editors:

I have read with interest your editorial of Aug. 15 on the subject of steel car design. Your thoughts regarding the stresses taken by the side sheathing when it acts in a girder are correct, but you state that in the New York cars these sheets take only tensile stresses. This is true of all plate girder designs, the size of plate being selected for its tensile value rather than its value in compression. The compression is taken care of in the top flange as well as in the stiffeners at the girder panel points. I think this same reasoning will apply to the side girder design of car.

Also, fundamentally, that portion of the car body above the sash rail is not properly designed to receive body stresses. In other words, the posts and letterboard form rectangles, like panels of a Pratt truss in which there are no diagonals or tension members. Of course, it is possible to increase the post section and the connections between the posts and the side girder and between the posts and the letterboard to transmit these stresses around the sash opening, but this would require an uneconomical use of metal and, consequently would increase the weight without increasing strength. Hence, I believe that the side-girder design, with the minimum economical thickness of side sheathing and with as light a structure above the sash rail as is consistent with economical maintenance, will provide a car body structure of minimum weight. STUDENT.

[It would be interesting if our correspondent would calculate the stresses due to horizontal shear in the side posts of a car with seven panels between truck centers, neglecting the overhang to simplify the problem and using the admittedly high moment of 800,000 in.-lb. and a 93-in. truss-side construction as assumed in Mr. McPherson's communication published above The weight of gusset plates and posts required to make the top plate effective would then cease to be a matter of personal opinion.—EDS.]

Association News

Secretary Burritt has recently spent some days at Atlantic City arranging the details of meeting rooms for the several associations. An announcement of these details will be given out soon.

The Chicago train committee has arranged with the Pennsylvania Railroad for a first-class, all-steel train to leave Chicago at 5 p. m. Saturday, Oct. 10, arriving at Atlantic City at 4 p. m. Sunday, Oct. 11. Applications for reservations should be sent to E. K. Bixby, Pennsylvania Lines, Chicago, Ill.

The following members have been secured to the Manufacturers' Association in the last week: Mark Mfg. Company, Chicago, Ill.; Hubbard & Company, Pittsburgh, Pa., and Nungesser Carbon & Battery Company, Cleveland, Ohio.

The joint committee held its final meeting for the year in New York on Aug. 26. Those in attendance were W. J. Harvie, chairman, with Allen & Peck; A. S. Richey, professor of electric railway engineering, Worcester Polytechnic Institute; C. L. Henry, president Indianapolis & Cincinnati Traction Company; W. S. Twining, with Ford, Bacon & Davis; Farley Osgood, assistant general manager Public Service Electric Company; P. H. Thomas, consulting engineer; F. B. H. Paine, consulting engineer; W. T. Oviatt, general superintendent Narragansett Lighting Company; Thomas Sproule, assistant engineer Philadelphia Electric Company, and F. H. Bethell, vice-president New York Telephone Company.

The committee considered suggestions which had been received from various members, and the report as originally prepared will be revised and submitted to the company members of the association.

Engineering Teachers at the Westinghouse Works

The fourth in the series of special summer courses for teachers in engineering schools which has been given at the works of the Westinghouse Electric & Manufacturing Company at East Pittsburgh has just closed. Representatives from Stevens Institute, South Dakota State College, Purdue University, Bliss Electrical School, Swarthmore College, Case School, Montana State College, University of Illinois, Virginia Polytechnic Institute, Virginia Military Institute, University of Nebraska, Colorado College, Yale University, Syracuse University, Georgia Institute of Technology and the Ohio State University were in attendance. The teachers were assigned to various departments, including work in the shops and on the test floor, and to investigation in the engineering department. In addition to the actual engineering work there are regular conferences, inspections of different departments of the factory and excursions to outside plants. The course affords an opportunity for teachers to get together to compare notes and become acquainted with some of the recent developments in manufacturing practice.

Overhead Problems—Catenary Construction—I

BY CHARLES RUFUS HARTE, CONSTRUCTION ENGINEER THE CONNECTICUT COMPANY

Catenary construction, hailed on its first appearance as a panacea for overhead troubles, is latterly being regarded with more sanity. For high-speed work on private right-of-way in its best form it is admirable, but for ordinary street work it is at least an inexcusable complication.

The fundamental purpose of catenary overhead is to afford sufficiently frequent support for the contact wire to obviate abrupt changes of direction vertically, and to keep low the stresses in the collector wire while permitting a wide spacing of primary support; on a well-designed system the collector raises the trolley wire very little and runs past a hanger as smoothly as past midspan. Essentially it consists of one or more main supporting members or messengers, from which is suspended either the contact wire, or a secondary messenger system in turn carrying the contact wire. Messenger spans are usually 150 ft. with wood pole support, and 300 ft. on steel bridges; hanger spacing, an even part of the span, is generally 10 ft. to 15 ft. for pantograph operation, and twice these values for wheel operation. For the 150 ft. spacing with wood poles, spans or brackets but little heavier than those for regular line construction are used. Span support has the marked advantage of causing minimum interference with the view of the engineman, but the sag must be great or the stresses will be very high. For heavy work most engineers have preferred a stiff cross member to the high or heavy poles required for span support. The latter has been used in some of the early light catenary construction and the New York, New Haven & Hartford Railroad has made extensive use of this treatment for yard work, and to a small extent for the main line, employing heavy lattice poles to sustain it; the new Pennsylvania overhead from Philadelphia to Paoli will employ it throughout. The span wire attaches to the main catenary messenger, while a steady strand attached at or near the contact wire prevents overturning under pantograph pressure. In some instances the span has contained a section of structural steel carrying insulators to which the messengers attach. The New Haven type has long wooden strains in the steady strand, very materially stiffening it; the Pennsylvania will also be of this form.

CATENARY CONSTRUCTION—EARLY FORM OF NEW HAVEN BRIDGE

BRACKETS AND BRIDGES

Brackets are of two classes: those made up of paired angles or channels, separated at one end, to go either side of the pole, to which they fasten by a through bolt, or to clasp a casting lagged or bolted to the face of the pole; and those consisting of a single I or T seating in a suitable pole casting. Paired member brackets offer facilities for the attachment of supports, insulators and the like; single member forms offer much less opportunity for corrosion. Brackets which clasp the pole and are through-bolted to it restrict the length of line affected by a break to a few spans either side, but the brackets at the break are usually badly crippled if not completely wrecked; brackets less rigidly secured swing clear, and while dropping a much greater

CATENARY CONSTRUCTION—TYPICAL EXAMPLES OF HEAVY ELECTRIC RAILWAY SUSPENSION ON THE PRINCIPAL SINGLE-PHASE LINES OF AMERICA AND EUROPE

length of line are usually injured little if any. Abroad, brackets on special iron poles are used for spans up to 300 ft., and frequently for double-track work, either with center-pole construction or carrying both trolley wires on the one long arm. In American practice two-track brackets are not so frequently used, spans or bridges being employed instead; the latter are also extensively employed on long span foreign lines.

Bridges have a wide range of design, from the light paired angle irons bolted to wooden poles, one on each side of the track, as on the Midland Railway, England, and certain Continental lines, and the light but rigid entirely structural material frames of the Archbold-Brady type, to the very substantial structures of the early New Haven work. The importance of the traffic involved in the latter case and the lack of data as to behavior in such service fully justified the use of a very conservative design in the pioneer installation.

The Continental tendency to soften lines often leads to ornate curved members and little scrolls on both brackets and bridges, which with our heavy construction would appear decidedly "gingerbready"; the American forms are usually severely plain. An arch, consisting of two latticed curved tapered columns with a trussed spreader, is used on a short experimental section of the New Haven, but the latest bridge with tapered posts, small end down, and curved brackets in the angle between post and girder, has a very pleasing appearance and is more readily fabricated.

CATENARY CHANGES

On the first catenaries the main messengers were carried, alive, on insulators mounted on the supports; better practice, however, is to put the insulators closer to the conductor. The latest New Haven form has grounded main messengers, one for each track which supports I-beams called cross-bents, in turn carrying insulators to which the secondary messengers are attached; the value of this grounded shield as a lightning protection has been strikingly shown in several electrical storms which caused troubles on the older forms, while the new construction in the same territory was entirely unaffected.

The earliest catenary consisted of a messenger from which the contact wire was suspended by a series of equidistant hangers. This worked well for short spans, but on long spans the great difference in length, and so in weight, of the mid and end hangers led to the development of compound catenary. The Siemens-Schuckert type, one of the earliest forms if not the pioneer, employs a main messenger, a secondary messenger suspended from the main messenger by hangers approximately 20 ft. apart, and a contact wire suspended from the secondary messenger by hangers approximately 10 ft. apart. The secondary messenger supports come at the quarter points between the main hangers or "droppers," which are of wire, about No. 8 gage equivalent, and are in two parts, linked eyes in the adjacent ends forming a flexible joint; these hangers attach rigidly to both main and secondary messenger. The secondary hangers attach rigidly to the contact wire, but loop over the secondary messenger so they are free to rise 2 in. or 3 in. This has proved very satisfactory in a number of Continental installations, and on the Midland Railway of England.

Of about equal age is the Westinghouse multiple catenary, with two main messengers which have vertical sag and horizontal deflection toward each other. The hangers, spaced 10 ft. apart, are equilateral triangles of pipe, the two upper corners attaching to the messengers while the bottom one holds the contact wire; the entire system is at line potential, the supports at the bridges being insulators as well. As first installed on the New Haven road, the contact wire, No. 0000 grooved copper, was carried directly by the triangles. These points, however, were exceedingly rigid while the midspan was comparatively soft, and when the speed of the train was such that the time interval between hanger points was the same as the vibration period of the collector, the latter chattered with increasing violence until changed conditions, which were not infrequently a broken wire, threw the pantograph "out of step."

The trouble was very satisfactorily obviated by a modification suggested by E. H. McHenry, then vice-president, as follows: A steel contact wire of the same section as the copper is suspended from the latter by clips coming midway between the triangles, which keep the wires 1¾ in. apart, center to center. The clips are rigidly attached to both wires; it was feared that with the heavy shoe pressure a looped clip such as is used in the Siemens-Schuckert form might permit the lower wire to turn sideways, in which case the shoe would foul the clips with disastrous results. The London, Brighton & South Coast Railway, to secure the same end, uses triangles of comparatively light wire, the small ones holding the wire by a loop, while the larger ones have jointed sides to give the desired flexibility. On this system the stresses are all low, the messenger having a sag of 6 ft. in vertical projection for a span of not quite 200 ft.

The extensive experience with the pioneer and McHenry forms under heavy service, and careful study of the behavior of other types has resulted in the McHenry-Murray catenary employed on the latest extension of the New Haven electrification. In this the main messengers, one for each track, have at the quarter points structural steel cross-bents which in turn carry insulators from which the secondary system is hung. This latter consists of the secondary messenger, carrying, through hangers 10 ft. apart, a pair of wires, upper of copper and lower of steel, held 1¾ in center to center by clips which are midway between the secondary hangers. The main messengers and the cross-bents are grounded, and the insulators have only to carry the mechanical load of the secondary system.

The Pennsylvania catenary consists of a main messenger for each track, carried by cross-spans. A paired wire like that of the New Haven, except that bronze is used instead of steel for the lower one, is hung from the main messenger, but these hangers are 20 ft. apart and come midway between every other pair of clips, thus cutting down the load materially.

The general tendency in catenary is towards a flexible line, but there are two recent marked exceptions. The Fischer-Jellinek form employed on the Budapest, Ueberetsch and other Austrian lines, has a triangular hanger which lies in the plane of the catenary and carries at the bottom angle an ear through which the trolley wire is free to slide. Continued and repeated use of this form apparently indicates successful results, but it is difficult to believe that even with the light bows employed there is not severe wear at these loose connections, particularly as the triangular hangers of this form, to insure that the clips remain parallel to the contact wire and do not bind on it, of necessity make very hard spots.

This type is hard incidentally rather than by design, but the Paul catenary of the Midi Railway, France, is essentially hard, the messenger supporting a trussed member, which is an equilateral triangle, a contact rail being secured to the lower vertex while pull-offs and steady braces attach to the top which is horizontal. The trusses are a trifle more than 40 ft. long and are suspended by their ends, there being four to the span. This ought to work well; the writer has always contended that it is abrupt change that causes trouble, and that a uniformly hard line would be as satisfactory as a uniformly flexible one, and hoped to see a rigid bar used on the original Westinghouse form; as a new proposition, however, the rigid construction is much more difficult to obtain.

For ordinary service simple catenary meets all requirements. On the Syracuse, Lake Shore & Northern and on the Rochester, Syracuse & Eastern Railways of central New York there have been used spans of 300 ft. on steel bridges of the Archbold-Brady type, the messenger having a sag of 79½ in. with rigid hangers 15 ft. apart. Long span installations are not so common, but spans of 150 ft. with wood pole support are to be found in all parts of the country, the sag for these ranging from 14 in. to 20 in., while the hanger spacing is from 10 ft. to 50 ft.

Bushings for Iron Armature and Axle Bearings

BY R. H. PARSONS, ELECTRICAL FOREMAN

In old-type motors serious trouble with the iron shells, which after being babbitted are used for armature and axle bearings, arises from the dowel holes. As these holes wear out of round and become too large for the dowel pins, they allow the bearing to move in the housing. The consequence is that the shell and housing are soon worn to such an extent that the bearing must be shimmed to secure a snug fit. As these shells are usually made of cast iron, it has not been found entirely satisfactory to fill the worn holes with new material either by the arc welding or oxy-acetylene process. An iron bushing screwed into the shell and drilled out to the proper size will give good results, but the method here described is cheaper and will work to better advantage.

The worn hole should be drilled to 1 in. or any other size that may be necessary to obliterate the old hole entirely, and then a hard brass plug should be driven into the enlarged hole. The length of the plug must necessarily be as great or slightly greater than the thickness of the shell, and the diameter of the plug should be large enough to require some force to drive it in. After the plug has been driven into the hole it should be upset or riveted into the shell by resting the bottom of the plug at the inside of the bearing on some solid base and hammering the top of the plug in order to force it more securely into the shell. The plug should not be tapered.

After the plug is filed on the outer side to conform to the surface of the shell the inside should be tinned. Then when the shell is babbitted, the brass plug will adhere to the babbitt. After being marked at the proper point, the plug can be drilled to fit the dowel pin when boring out the bearing.

When the plug is so worn again that the hole is too large it can easily be knocked out for replacement by a new one.

The Return Circuit — Selection and Location of Bond

BY HOWARD H. GEORGE, ASSISTANT ENGINEER MAINTENANCE OF WAY, PUBLIC SERVICE RAILWAY, NEWARK, N. J.

An important feature in rail bonding is the proper cross-section for any given length, and the available space beneath the joint plates. While a bond of No. 00 capacity and 8 in. or less in length may prove entirely satisfactory, it would not be possible to obtain satisfactory results with a 500,000 circ.-mil. bond of the same length. To obtain the necessary flexibility it is essential that a bond of such capacity be at least 14-in. in length and preferably from 16 in. to 18 in. For the same reason a No. 0000 bond should preferably not be less than 10 in. long.

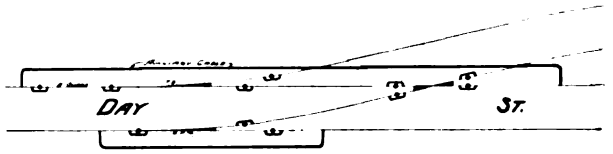
Clearance Under Plates and Proper Length of Bond

The determination of the proper section of bond for any given clearance under the plates cannot be decided by any fixed rule. A safe practice is to allow 1/16 in. as a minimum clearance at all points, and the shape and location of the crimp in the flexible part of the bond must be determined by such conditions as location and size of bolt and bond holes, and whether single or double bonding is to be employed. In connection with the above, it might be mentioned that the plates designed for the standard rails of the American Electric Railway Engineering Association provide adequate clearance for bonds under the plates.

It is probably true that most of the trouble which has been experienced from crystallization and consequent breaking of rail bonds has been due to the fact that the bond used was not flexible enough to provide for the deflection and vibration of the bond under wheel loads and rail movements due to expansion and contraction. Experience has shown that any kind of bond placed beneath the joint plates should be at least 10 in. long, and the general modern practice is to allow for a bond from 12 in. to 16 in. in length. On a 550-volt circuit cross-bonds should be placed approximately every 1000 ft. In cross-bonding the rails of a track, the length of such bonds should be at least 12 in. more than the gage of the track. In the use of exposed bonds, that is to say, bonds which are installed around the outside of the joint plates, such bonds should be at least 10 in., and preferably 12 in., longer than the plates, so that the latter may be removed or the bolts driven with a spike maul and the nuts tightened without danger of injury to the bond.

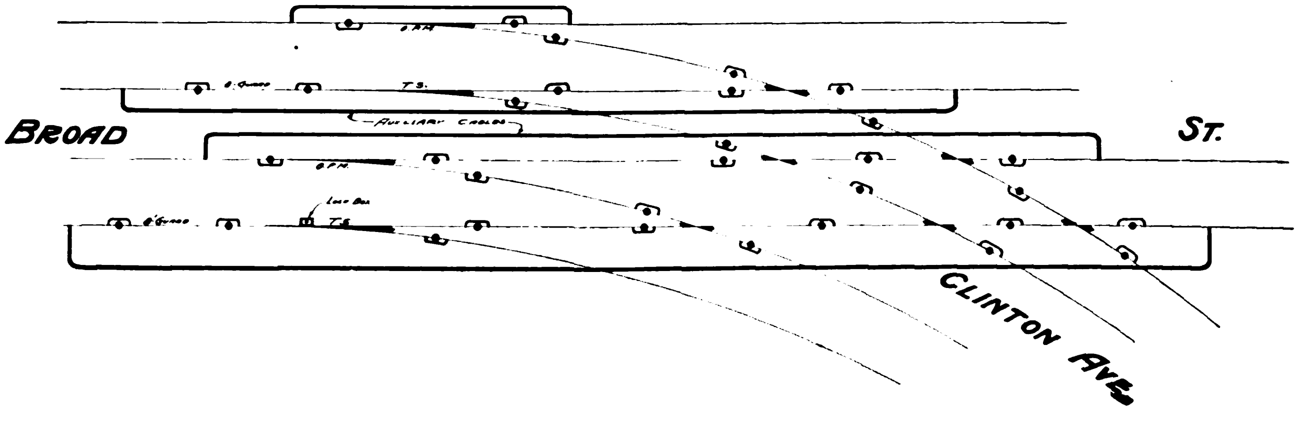
Location of Bond Holes and Relation to Bond Failures

From data collected, it seems to be the general practice to space the terminals midway between the first and second bolt holes, or between the second and third bolt holes. In no case should the bond holes be located close to the ends of the rails, as it has generally been found that the shock from the wheels pounding on the rail ends is dissipated through the copper at the point where it is fixed rigidly to the rail, and this has a tendency to shorten the life of the copper. The increased life and efficiency of the longer bond will generally more than offset the increased cost of the copper as well as the increased energy loss due to increased joint resistance, since the increased flexibility lessens the leverage which the different rail movements tend to exert at the point where the body of the bond joins the head.



RETURN CIRCUITS—PUBLIC SERVICE RAILWAY BONDING INSTALLATION AT A SIDE TURNOUT

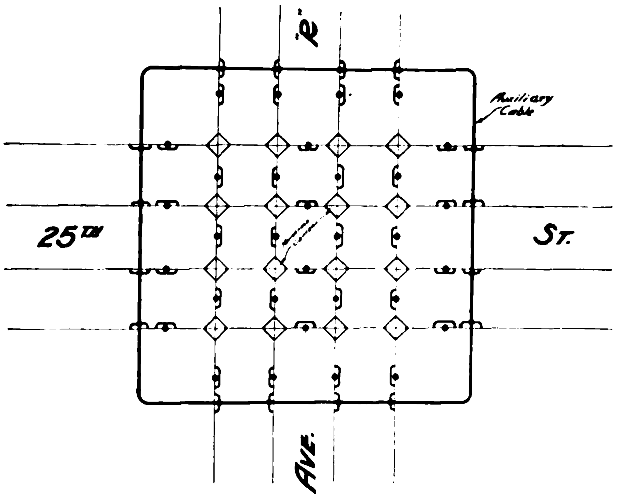
Another explanation offered by some for the loosening of bonds is that when the steel contracts, due to temperature changes, it shrinks around the bond terminal and compresses the copper, causing it to flow slightly. Then, when the steel heats up again, the rail expands and leaves the copper terminal slightly loose in the hole through the rail web. This theory, however, is not generally accepted, as it is believed that the copper is greatly hardened when the taper punch is driven through the terminal or when the hydraulic compressor is applied, giving it a much higher elastic limit and thus permitting a much larger deformation to occur without a permanent set taking place.



RETURN CIRCUITS—PUBLIC SERVICE RAILWAY BONDING LAYOUT FOR A DOUBLE-TRACK BRANCH-OFF

Resistance of Various Types of Bond Terminals

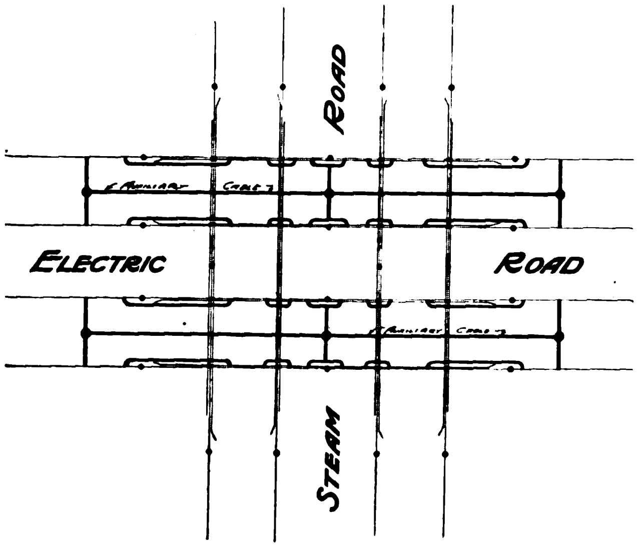
Relative to the efficiency of various types of bonds, it is interesting to note that tests made by one street railway showed that the resistance of a hydraulic compressed bond was 3.35 per cent less than the resistance of a pin terminal bond of the same length and capacity. Still other experiments made at the same time showed that the contact resistance was decreased about 6 per cent by the use of mercury amalgam. Of course the hydraulic compressor is a more expensive and complicated piece of machinery than the outfit which is required for the installation of pin terminal bonds, and the labor required might have to be of a higher class, thus making the bonding cost more. The foregoing tests of the relative resistance of bonds of the same length and capacity but with different types of terminals were made as an experiment. Without doubt, they were made under ideal laboratory conditions, but these conditions were alike for all bonds tested and the results obtained are therefore comparative.



RETURN CIRCUITS—BONDING LAYOUT OF THE PUBLIC SERVICE RAILWAY AT A STREET CROSSING

BONDING THROUGH SPECIAL WORK—EQUIVALENT RAIL RESISTANCE

One part of the track return circuit which is very liable quickly to lose its efficiency as a conductor is that through the special work. For this reason it is not only necessary to bond each individual joint through the entire layout, but it is also necessary to install auxiliary cable bonds running completely through the special work, and connected with the track beyond the limits of the layout. Four accompanying diagrams show the standard method of bonding through some typical special track layouts on the property of the Public Service Railway.

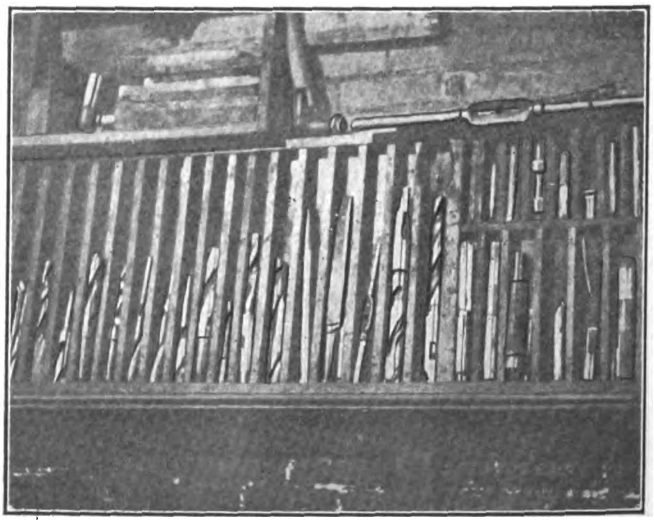


RETURN CIRCUITS—TYPICAL SPECIAL WORK BONDING LAYOUT AT A STEAM-ELECTRIC CROSSING

It is customary to express the resistance of a joint in terms of the resistance of a length of unbroken rail. There is a large difference of opinion as to the proper equivalent in determining whether the joints should be rebonded or not. For instance, one of the questions in the American Electric Railway Engineering Association Question Box (*Proceedings*, 1911) asking the proper figure for this purpose, brought twenty-three replies. Four men agreed that 5 ft. of unbroken rail should be used, three thought 6 ft. was the proper figure, and the rest thought still other lengths should govern. Not more than two of the remaining sixteen concurred as to the proper length, their replies ranging all the way up to 12 ft. of unbroken rail. It would not seem proper to adopt any standard equivalent length to cover all conditions, because the length which would be correct for track in the center of a heavily loaded traffic zone or near the power station would be unreasonable for the outer ends of some suburban lines. Therefore it is not just to classify all joints of a certain fixed length as good, and all more than that length as poor. Bonding may be in A-1 shape and still show a resistance reading greater than the established maximum, because such an expression of the resistance of the joint will depend on the length and size of the bond itself, conductivity of the steel rail, temperature, etc. To determine whether the joint should be rebonded or not, the permissible energy loss or voltage drop across the joint must first be established, and, knowing the resistance of a properly bonded joint, the calculation of the maximum permissible joint resistance can easily be made.

Saving Trips to the Stock Room

At the St. John Street shops of the Portland (Maine) Railroad frequent trips of machinists to the stock room are avoided by the storage of drills and arbors in a home-made wall rack shown in the accompanying half-tone. The rack, which is 7 ft. long and 20 in. high, is divided into fifty-six compartments by 5/8-in. separating sticks. It is mounted about 17 in. above the bench near the principal machine tools and has proved a great convenience to employees.



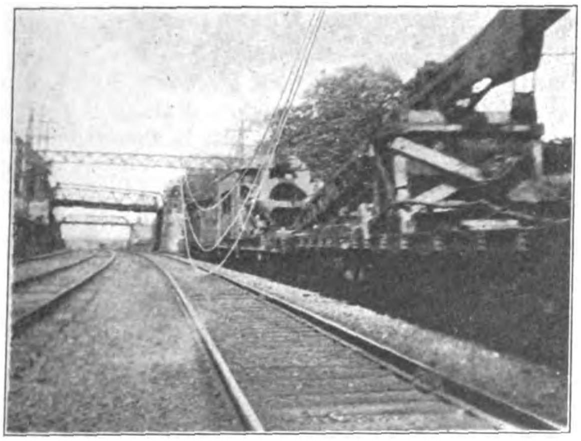
AUXILIARY DRILL AND ARBOR RACK AT PORTLAND, MAINE

The coal contract for the Cincinnati (Ohio) Traction Company has been closed for the next three years. The business will be divided between the Cabin Creek Coal Company and Matthew Addy & Company, both of Cincinnati.

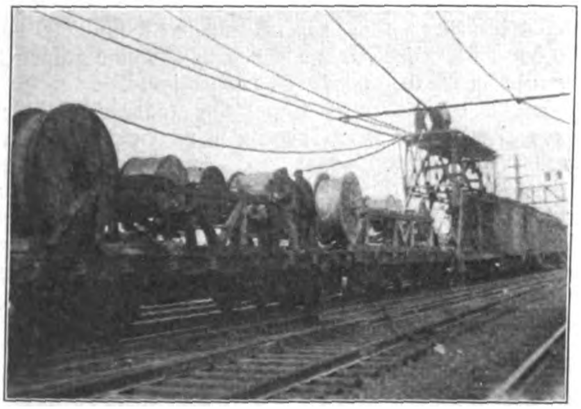
New Haven Railroad Construction Notes—Pulling 5/8-In. Messenger and Copper and Steel Trolley Wire

BY A FORMER INSPECTOR

The engine, reel car, tool car and coach shown in the accompanying views were used in the electrification of the New Haven Railroad for pulling a 5/8-in. steel messenger, a copper and a steel trolley wire. The reel cars were loaded with one reel of 5/8-in. steel messenger, two reels of No. 0000 copper and one reel of No. 0000 steel trolley. The average length of the messenger wire was 10,000 ft. One view shows the train in operation. At the point where the pull was to be started the train was stopped to bring the tower car under the anchor bridge. A 1¼-in. turnbuckle and a high stress dead-end insulator were then attached to the bridge. Next the 5/8-in. steel messenger was taken up from the reel over the top of the tool car to the top of the tower car and attached to the insulator with an open socket. The copper and steel trolley were brought up in the same manner, made up into coils about 150 ft. long and left on the anchor bridge for connecting to the run from the other side. Then the trolleys were attached to the 5/8-in. steel messenger with Crosby clips. After all wires were thus secured, the train was run ahead to the first I-beam bent of the overhead line, where the 5/8-in. messenger was put into the clamps of the main line insulator, leaving it loose so that the cable would run freely, as shown in one of the views. The copper trolley was tied loosely with a heavy tie wire on one side of the insulator and with the steel trolley wire on the other side so that both trolleys would run freely. This method was repeated to the end of the run. After pulling out the first reel of copper trolley, the wires were pulled up one at a time by the train. A Crosby clip was put over the 7/8-in. messenger cable, and any of the three wires (namely, 5/8-in. messenger, No. 0000 steel or No. 0000 copper) was then put into the U-bolt of the Crosby clip and pulled up until it was tight. Following this, the clip was tightened to hold it in place. After all three wires were thus pulled up and tightened, the train ran ahead and the cable was pulled up and tightened in the same manner. The upper views show the three wires in the center of the track before they were pulled up.



THE 5/8-IN. STEEL AND NO. 0000 COPPER AND STEEL TROLLEY WIRES OVER CENTER OF TRACK BEFORE BEING PULLED UP



TRAIN FOR PULLING 5/8-IN. MESSENGER AND NO. 0000 COPPER AND STEEL TROLLEY IN OPERATION

Auxiliary Wiring of Interurban Cars

BY J. N. GRAHAM, MASTER MECHANIC ROCKFORD & INTERURBAN RAILWAY COMPANY

The accompanying table and drawing will illustrate the method used by the Rockford & Interurban Railway for wiring light and pump circuits in its interurban cars. These prints are also used by the shopmen to locate trouble on these circuits. By controlling the marker circuits with three-way switches it is possible to carry either white or green signals on the front of car or no signals, as desired. As the incandescent headlight is also operated with a three-way switch, it can be turned on as the arc headlight is turned off when entering a city where the use of arc headlights is forbidden.

WIRING OF LIGHTS, AIR, ETC., ON THE CARS OF ROCKFORD & INTERURBAN RAILWAY

General: All fuses connected to main trolley.

Air compressor connection: From fuse to switch, from switch to governor, from governor to compressor.

Arc headlight connection: From fuse to switch, from switch to headlight resistance, from resistance to headlight plug.

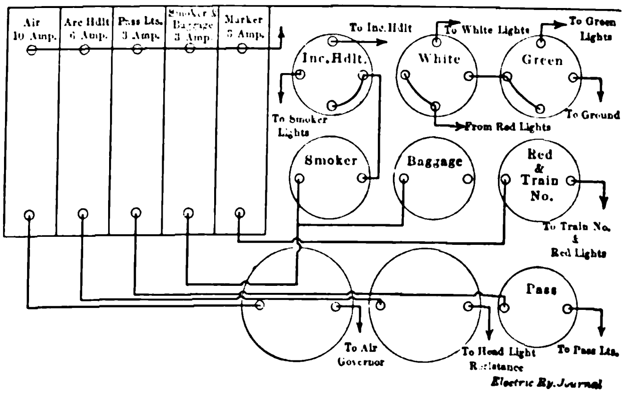
Passenger lights connections: From fuse to switch, from switch to light circuits in passenger compartment of car.

Smoker lights connections: From fuse to switch, from switch to positive pole of three-way switch, from one negative pole of three-way switch to incandescent headlight, from incandescent headlight to smoker lights, from the other negative pole of three-way switch direct to smoker lights.

Baggage lights connections: From fuse to switch, from switch to baggage lights.

Marker lights connections: From switch to train number light, from train number light to red lights and rear platform lights, from rear platform lights to positive pole of first three-way switch, from one negative pole of first three-way switch to white lights, from white lights to ground; from the other negative pole of first three-way switch to positive pole of second three-way switch, from one negative pole of second three-way switch to green lights, from green lights to ground; from the other pole of second three-way switch to ground.

All circuits to be grounded.



PLAN OF SWITCHBOARD FOR AUXILIARY WIRING, ROCKFORD & INTERURBAN RAILWAY'S INTERURBAN CARS

Municipal Railway Machine Shop at San Francisco

All of the repair equipment, now being installed in the Geary Street shop of the Municipal Railway at San Francisco, is driven by direct-connected motors. The railway buys power in the form of direct current at 500 volts for 1 cent per kw-hr. while the rate on other voltages is 3 cents per kw-hr. It was therefore found economical to install in the shop a motor-generator set of 75-kw capacity. This set takes 500-volt current from the supply mains and delivers 230-volt current to the motors in the shop.

The shop equipment includes the following:

One 42-in. Niles wheel-turning lathe, with boring attachment, 30-hp motor.
One 300-ton hydraulic press, 7½-hp motor.
One 24-in. Reed lathe, 7½-hp motor.
One 19-in. Le Blond heavy duty lathe, 5½-hp motor.
One 14-in. Hendy Norton lathe, 2-hp motor.
One 3-ft. Dreses radial drill, 3½-hp motor.
One 20-in. Barnes drill, 1½-hp motor.
One 24-in. Kelley shaper, 5-hp motor.
One No. 7 Racine high speed hack saw, 1½-hp. motor.
One Universal wood working machine, 10-hp motor.
One Beaudry power hammer (300-lb.), 7½-hp motor.
One Bridgeport wet and dry emery wheel, 3-hp motor.
One 2-ton Euclid electric hoist.

Eight Gas-Electric Motor Cars for St. Louis Southwestern Railway

The St. Louis Southwestern Railway is placing in operation the first lot of eight gas-electric motor cars that are now being received from the General Electric Company. At this writing four cars are in use. Car No. 10 is now making the trip between Shreveport, La., and Lewisville, Ark., a distance of 62 miles. Along the route are ten regular stops, seven flag stops and four railroad crossings. The time required for the run is two hours and thirty minutes. The car makes one trip each way a day, totaling 124 miles. Car No. 11 recently made the initial run between Commerce and Sherman, Tex., a distance of 57 miles. The car left Commerce at 8 a. m. and arrived at Sherman at 10.40 a. m. Returning it left Sherman at 4 p. m. and arrived at Commerce at 6.40 p. m.

In the formation of the St. Louis Southwestern Railway are included the Pine Bluff Arkansas River Railway, the St. Louis Southwestern Railway of Texas and the Eastern Texas Railroad. It is known as the "Cotton Belt Route" and its total trackage is 1810 miles standard gage. Starting at St. Louis, Mo., it follows a southwesterly direction across Arkansas into Texas. Here at Mount Pleasant one branch terminates at Fort Worth and the other runs through Waco to Comanche and to Stephenville. Branches connect with important centers like Cairo, Ill.; Memphis, Tenn.; Little Rock, Ark., and Dallas, Tex. The equipment of the road comprises 242 locomotives, 235 passenger cars, and 12,445 freight and miscellaneous cars.

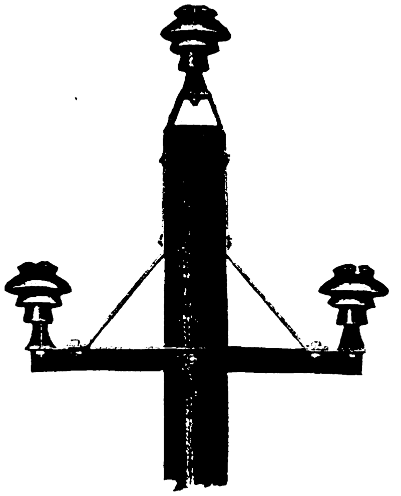
All the gas-electric motor cars for this railway are what is known as type RE-70-B-11. The specific dimensions of the St. Louis Southwestern cars are 70 ft. 1⅜ in. over bumpers by 10 ft. 6¾ in. wide over all. They weigh approximately 49 tons, have a seating capacity for sixty-two passengers, two per seat, and are each equipped with two GE-205, 600-volt, box frame, commutating pole motors having a total of 200-hp capacity. The motors are mounted with nose suspension directly on the axles of the forward truck. The generating unit consists of an eight-cylinder, four-cycle gas engine of the "V" type, direct-connected to a 600-volt, commutating pole generator.

The interior of the cars is partitioned into four compartments. The cab in front containing the power plant apparatus measures 11 ft. 11 in. long; next is the baggage room, 10 ft. 11⅞ in. long; then the smoking section, 12 ft. 5 in. long, and the passenger compartment, 30 ft. 5⅞ in. long. The body of the cars is of all-steel construction, except the seats and interior finish, which are of mahogany. Rear platform entrances are provided. The trucks are of the heavy spring bolster type with elliptic bolster and coil equalizer springs.

Triangular Arms for High-Tension Lines

The Electric Service Supplies Company has placed on the market a new angle-iron cross-arm to be known as the "Keystone" triangle arm. As will be noted in the illustration it consists of an angle-iron cross-arm with braces on either side which are continuous and which form a ridge iron over the top of the pole for a third insulator. The cross-arm proper is shaped to allow the insulators to be on a line with the center of the pole and so that braces and top insulator will also be centered.

To install this arm it is necessary only to shave off two sides of the pole at the top so that it will fit the brace, and to bore three holes. The cross-arm proper does not require gaining. This small amount of preparation can be very readily and accurately done by means of a template where a large number of poles are to be erected. On account of the superior bracing qualities of this cross-arm only three ¾-in. through bolts are required to secure it permanently to the pole. On large installations the minimum time necessary to install these triangle arms should result in some appreciable saving.



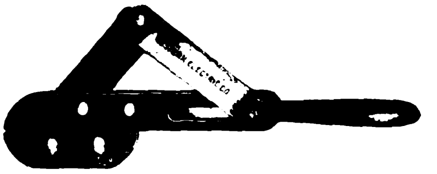
TRIANGULAR CROSS-ARM FOR HIGH-TENSION LINE

Triangle cross-arms are made from 3-in. x 3-in. x ¼-in. steel angle and ¼-in. x 3-in. flat steel. They are made for three-phase circuits up to 35,000 volts and for 50,000-volt, three-phase circuits. Their approximate weight is 36 lb. and 49 lb. respectively.

Probably the most important feature of this new cross-arm is its great strength, particularly where the pull is downward or at any lower angle therefrom. This is partly due to the equal distribution of weight on either side of the pole, and finally to the exceptional bracing and the improved design and great strength of every part. Other claims made for this cross-arm are that the bolts are placed through the pole in opposite directions, giving exceptional rigidity to the installation; that the wires are in a true triangle and all in different vertical planes, thus decreasing the possibility of a short-circuit due to the breaking of an upper wire, which short-circuit is quite possible from some of the varied methods now in use for supporting high-tension transmission lines; that a maximum height of pole is secured in that the ridge iron is actually an extension to the pole, thereby allowing a shorter pole for a given height of wires. Ground wire supports or bayonets when used in connection with these cross-arms are attached by means of the two through bolts which support the upper section of the triangle. They are of the off-set type and are made from 3-in. x 3-in. x ¼-in. steel angle.

A Lineman's Grip

A lineman actually requires three hands to do his work efficiently, a hand for each wire and a third to do the tying or splicing. The Western Electric Company's "Buffalo" grip illustrated does the work of a third hand. Its jaws may be clamped open at any width, the grip held in one hand and the wire inserted, no matter in what position the lineman may be. The locking device makes this possible, while the rest of the construction is such that pulling only serves to strengthen the grip on the wire. The jaws of drop-forged steel will not injure the softest wire or insulation. The grip is made with and without pulley attached. It will hold all sizes of wire, bare and insulated, up to and including No. 0000 B. & S.

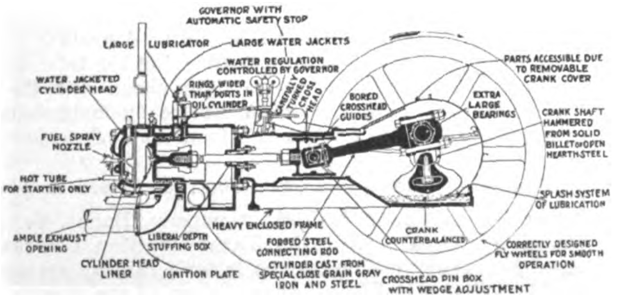


LINEMAN'S GRIP CLOSED

A New Valveless Two-Cycle Oil Engine for Low-Grade Fuels

An oil engine of the valveless two-cycle, low-compression type has recently been brought out by the Chicago Pneumatic Tool Company. This engine can be operated successfully on gasoline, kerosene, crude oil or practically any of the intermediate grades of distillates, and it is, therefore, especially adapted for use in operating air compressors or generators in construction work, the design being exceptionally simple so that satisfactory operation is assured notwithstanding the rough handling likely to be involved in such service.

The engine differs materially from the customary form of two-cycle machine, as it is provided with a piston-rod and cross-head instead of the usual trunk-piston. The compressed air for scavenging after each explosion is obtained by the motion of the piston head in a chamber that is separated from the crank case. The crank case, therefore, does not have to be inclosed, and lubrication of the cranks and cross-head is not affected by the heat from the cylinder. Ignition is obtained by spraying the fuel, which is forced into the cylinder by a small pressure pump, against a hot plate attached to the piston head, a hot tube being used for starting. With the fuel a quantity of water is injected to reduce the temperature of ignition and the supply of water is regulated automatically by the governor, the supply being proportioned to the quantity of fuel injected.



GOVERNOR WITH AUTOMATIC SAFETY STOP
LARGE LUBRICATOR
LARGE WATER JACKETS
WATER REGULATION CONTROLLED BY GOVERNOR
WATER JACKETED CYLINDER HEAD
RINGS WIDER THAN PORTS IN OIL CYLINDER
CAREFULLY TURNED CROSS HEAD
BORED CROSSHEAD GUIDES
EXTRA LARGE BEARINGS
PARTS ACCESSIBLE DUE TO REMOVABLE CRANK COVER
CRANK SHAFT HAMMERED FROM SOLID BILLET OF OPEN HEARTH STEEL
FUEL SPRAY NOZZLE
HOT TUBE FOR STARTING ONLY
SPLASH SYSTEM OF LUBRICATION
HEAVY ENCLOSED FRAME
AMPLE EXHAUST OPENING
LIBERAL DEPTH STUFFING BOX
FORGED STEEL CONNECTING ROD
CRANK COUNTERBALANCES
CORRECTLY DESIGNED FLY WHEELS FOR SMOOTH OPERATION
CYLINDER HEAD LINER
IGNITION PLATE
CYLINDER CAST FROM SPECIAL CLOSE GRAIN GRAY IRON AND STEEL
CROSSHEAD PIN BOX WITH WEDGE ADJUSTMENT

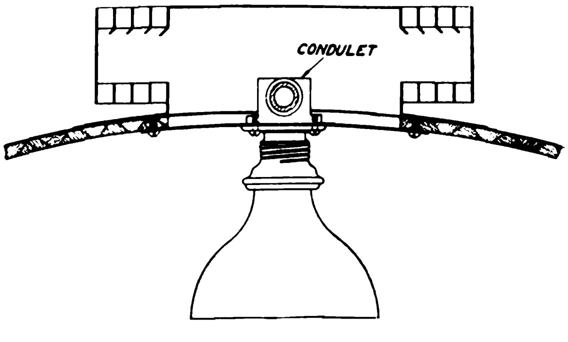
ELEVATION OF OIL-ENGINE SHOWING COMPRESSION CHAMBER SEPARATE FROM CRANK CASE

Ramp-Floor Semi-Convertible Cars for Portland, Maine

The Cumberland County Power & Light Company, operating the electric railway service of Portland, Maine, is equipping ten new cars at its St. John Street shops. The cars are of the semi-convertible type and were built by the Wason Manufacturing Company, Brightwood, Mass. They are designed for prepayment service and are provided with steel underframes and sides up to the belt rail, with an over-all length of 42 ft. 8 in., a seating capacity of forty-four passengers and an over-all width of 8 ft. 3 in. An interesting feature of the design is the use of inclines in the floor for a distance of 6 ft. back of each vestibule, the drop being 3 in. to permit the use of a lower step from the street level. The step heights are 13 in. for each of the first two steps from the ground, the third step being 10 in. high. The steps will fold in conjunction with the vestibule doors, the exit door in the forward end being operated by a pedal under the control of the motorman. The cars are built for double-end operation, each platform being 5 ft. 6 in. long, and are equipped with four GE 40-hp motors each, mounted on Brill 51-E trucks. Johnson fare boxes, Flexolith flooring and Holophane reflectors equipped with 60-watt lamps are among the other features. The interior car lighting is cared for by ten lamps. The fare and transfer register in each car will be operated by pipe levers controlled by pedals mounted above the vestibule floor at the conductor's position, the lever at each end of the car being a ½-in. rod carried inside a 1¼-in. vertical pipe run from the fare box to the roof.

Combined Honeycomb Ventilator and Lamp Fixture

The Railway Utility Company, Chicago, has just put on the market a combined honeycomb ventilator and lighting fixture. The purpose of this fixture is to economize space, and the heating effect of the lamp also aids in ventilating the car when it is standing still. The fixture is easily detached from the supporting condulet, and the connections to the wiring circuit are made on a neat molded block inclosed in the condulet, no soldering of joints being required. This provides a substantial construction which eliminates all chance of wiring difficulties. The shade is held by a special design of holder which provides a flexible grip on the shade, easy to manipulate, and a positive lock. This combined ventilator and lamp socket has been adopted by several steam railroads and is used on the low-level, end-entrance cars of the Third Avenue Railway, New York.



COMBINATION OF HONEYCOMB TYPE VENTILATOR AND MODERN CAR LIGHTING FIXTURE

News of Electric Railways

Hearing on United Railroads and Solano Project

The hearing being conducted by the California Railroad Commission in the case of the United Railroads of San Francisco was continued on Aug. 24. At the last meeting President Lilienthal of the United Railroads agreed to see what he could do to discover the sources of the money contributed to the Solano Irrigated Farms Company. He was the principal witness at the hearing on Aug. 24. He reported that his examination of the books of the Solano Irrigated Farms Company showed that the company had received $1,180,000 in cash from all sources. This amount included about $292,000 which did not come from Mr. Calhoun, former president of the United Railroads of San Francisco. As the investment from funds of the United Railroads in the Solano project amounted to $1,096,000, this left a balance of about $208,000 which, according to the testimony, had not been accounted for.

At the conclusion of Mr. Lilienthal's testimony the commission advised him to refer these findings to the district attorney. It then instructed its secretary to refer all of the evidence in hand to the district attorney.

The remainder of the hearing on Aug. 24 was devoted to a discussion of the methods of accounting followed by the United Railroads. No recommendation was announced in this matter. At the close of the hearing on Aug. 24 the commission announced that the case against the company was adjourned until Aug. 28.

Need for Cleveland Improvements Misunderstood

In the department "Financial and Corporate," elsewhere in this issue, mention is made of the restoration of the transfer charge by the Cleveland (Ohio) Railway and the statement of earnings of the company for July, 1914, and July, 1913, is published. The charge is made by Councilman William Stolte that the company is spending too much money for carshops and buildings and is not endeavoring to keep the fare at 3 cents. He also accused Peter Witt, street railway commissioner, of recommending the expenditure of too much money and said that with the execution of such plans as have been made the rate could never be maintained because of the excessive interest charges. Councilman J. J. McGinty expressed similar views. It is a fact that the company is investing considerable money in shops and division buildings, but this work was delayed for years by the controversy between the city and company. The criticism has come from members of the Council who have not been in close touch with the history of the road and not from the special committee which did study the matter some time ago. The increase in the deficit is partly due to the charges of $18,000 per month, made for the abandonment of power equipment and cars and restoration of the maintenance fund. Since the company was not free to take care of the loss in its own way, the charge had to be made.

Councilman Robert Koch, chairman of the street railway committee, has announced that he will favor the adoption of a flat rate of three tickets for 10 cents in place of the charge for transfers. He argues that the charge for transfers is unfair. This announcement has provoked some discussion of the zone system.

George R. Davies, president of the local branch of the Amalgamated Association, presented another proposition to the company on Aug. 22. It provides for an increase in wages from 27 cents to 30 cents for first-year men and from 30 cents to 35 cents an hour for the men who have been in the service for more than a year. There is a further provision that the minimum work day shall be eight hours and the maximum day, nine and a half hours, 75 per cent of all runs to be made within twelve consecutive hours and the other 25 per cent within fourteen consecutive hours. This change in hours would necessitate a revision of the schedules and seriously affect the cost of operation. J. J. Stanley, president of the company, said that any proposed arbitration must be made on the basis of the original demands, and on Aug. 25 forwarded a communication to the local union refusing the latest demands for increased wages and readjustment of the length of the work day.

Northampton Strike Settled

The strike of the employees of the Northampton (Mass.) Street Railway, which was begun on Aug. 19, was settled on Aug. 25 through the efforts of Bernard F. Supple, secretary of the Massachusetts Board of Conciliation and Arbitration. An agreement has been signed by the company and the local branch of the Amalgamated Association, under the terms of which all employees were to return to work without prejudice and all motormen and conductors receive an increase of 2 cents an hour above their previous rate of pay, employees in carhouse, line and track departments to have an increase of 2½ cents per hour in wages. Motormen and conductors will now receive a minimum of 25 cents an hour in a graduated scale of wages reaching a maximum of 30 cents an hour at the end of six years' service. An extra daily time allowance of ten minutes will be granted for taking out and putting up cars and making reports to the company. The company agrees so far as possible to arrange its schedules of regular runs on the nine-hour basis. As a result of the agreement, the men gain an increase of 2 cents an hour in all grades over the schedule awarded by the recent board of arbitration, while the company is not obliged to grant the demand for $3,600 in back pay for which the men contended, and the men are required to work on platform time. From June 1, 1914, the men receive increases reaching an estimated total of $3,600 per year and the agreement is to remain in force until June 1, 1916.

Beginning Promised on New Buffalo-Niagara Line

According to the Buffalo *Commercial* the International Railway, Buffalo, N. Y., is planning to carry out at once all the preliminaries looking toward the construction of the proposed Frontier Electric Railway on a private right-of-way between that city and Niagara Falls, first proposed about a year ago. In this connection E. G. Connette, president of the company, is quoted as follows:

"The building up of Buffalo, the Tonawandas and Niagara Falls, the increase of traffic between these cities throughout the year and in addition to that the ever-growing tourist travel to and from the falls have made it necessary to go ahead with such an extension and expansion of the International's interurban service.

"We have realized the advantages of a direct trunk-line high-speed service between Buffalo, the Tonawandas and the falls, but it was inadvisable to build a parallel or additional route across the Niagara frontier until the local inter-communication on the present Niagara Falls route grew to such a point that the traffic there would maintain the old line and give the company an opportunity to develop a separate trunk line service.

"It is well understood that it would be difficult to finance a big undertaking at the present time, but the International Railway is in a position to go right ahead with the first portion of this new interurban service by laying out and grading the roadbed for the new trunk route."

Thirty-Year Railway Power Contract Closed in Texas

The Texas Power & Light Company, Dallas, Tex., has closed a contract with the Texas Traction Company to furnish energy to operate the latter's railway system and has leased the McKinney power plant of the railway company. The contract covers the sale of $100,000 worth of energy annually for thirty years. Lines will be constructed connecting the present "transmission district" of the Texas Power & Light Company with the northern group of cities served by the company. Construction will also be begun soon on the new power plant for the latter company on the Oklahoma bank of the Red River.

At present the Texas Power & Light Company operates in thirty-three Texas communities having an aggregate population of 212,000. Its connected load in lighting aggregates 14,000 kw and in motors 12,401 kw. In addition, it operates 3200 street lamps and sells energy to several interurban railways. This railway load alone amounts to 2300 kw and consumes about 1,300,000 kw-hr. each month.

Cotton gins, oil mills, cotton mills, city water pumping and railroad shops make up the principal classes of its industrial customers, while the company has one user, a cement plant, which, with a connected load of 3500 kw in motors, consumes 2,500,000 kw-hr. per month.

The majority of the thirty-three communities now served by the Texas Power & Light Company lie quite close together geographically, and already some twenty-three of them have been linked by the high-tension lines of the company and compose what is known as its "transmission district." This entire central system is fed with energy from two steam plants at opposite ends of one of the main transmission circuits. The communities outside the present transmission district are now served by individual steam or Diesel-engine plants, but will later doubtless be reached by the high-tension network as this is extended from its present nucleus.

The Opportunity of the Panama-Pacific Exposition

C. C. Moore, president of the Panama-Pacific International Exposition at San Francisco, states that at no time had the directors a thought of postponing the opening date of the exposition on account of the European war. Forty-four states of the Union have made appropriations and are actively engaged in building state pavilions and preparing their exhibits. The various state appropriations are made for a stated period, and a delay in the exposition would necessitate going to the legislatures for more money. The exhibit palaces are completed and the installations have already begun on a large scale. Thirty-four foreign nations have made appropriations and are actively engaged in erecting their official buildings and preparing their exhibits regardless of war, so that any postponement in the exposition would complicate the situation. Of the foreign nations that are now preparing buildings and exhibits, only three are concerned in war, and none of these has indicated that its arrangements for participation will be interrupted. France and Italy have cabled that their preparations to participate are proceeding despite the war. The Argentine government cabled on Aug. 13 that it was preparing to increase its exhibits and accordingly requested the exposition officials to assign additional space. Brazil also cabled that it intended to proceed with larger plans for an exhibit at the exposition. For the first time in its history China has made application to display machinery, and space has been assigned the Chinese Republic in machinery palace in addition to assignments in the other exhibit palaces. The operation of the new regional banks and the added number of ships flying the American flag and making quick time from coast to coast, through the Panama Canal, places the United States in a most favorable position to bring American manufactures to the attention of the distributors and consumers of the world who are at peace.

Hearings on Location of Kansas City Interurban Terminal

Public hearings on the location of the new interurban railway station in Kansas City, Mo., were held during the week ended Aug. 22 by the board of control of the Kansas City Railways. Citizens interested in the various sites presented their arguments, and plans for financing the building were outlined. Several groups offered definite building plans. In most cases the suggestions were for a building of several stories to occupy a block. The board has instituted an investigation of the subject for itself. Among the details which will influence the result are the currents of traffic and the comparative number of transfers as shown by the records. It is said that 40 per cent of the passengers on the interurban railways now transfer to the Kansas City Railways. This would indicate that only 60 per cent would stay on the cars to the station. There is also a large amount of transferring from the city lines to outbound interurban cars. Another factor is the traffic on the interurban railways in connection with the old Union depot in the west bottoms. This will be radically changed, perhaps, when the new union station is opened.

The physical plant of the Kansas City Railways has been improved under the receivers. About three years ago special reports made to the engineers showed that nearly 70 miles of track needed immediate attention, and repairs were begun. The chief trouble was due to paving and the depreciation of the foundation of the rails. It is said now that less than 6 miles need attention. Some heavier rails have been laid, notably near the new union station and in the west bottoms where the cable line will be replaced by electricity.

New Colorado Commission

Governor Ammons, of Colorado, has named George T. Bradley as a member of the State Public Utilities Commission which replaced the State Railroad Commission of Colorado on Aug. 13. When the public utilities law was enacted it provided that A. P. Anderson and S. S. Kendall, two of the members of the Railroad Commission, should be two of the three members of the new commission. Mr. Bradley is the third member. The law was suspended until Aug. 13 through the filing of a referendum petition, but Judge George W. Allen, of the district court, recently held the petition was fraudulent, and enjoined the Secretary of State from submitting the law to the people. The act extends the jurisdiction formerly exercised by the State Railroad Commission, which had control only over railroads, to every form of public service, including telephone, water, light, power and telegraph. Mr. Anderson, of the commission, said:

"While the new act requires a much larger office force than we now have, we do not propose to make any very large extension of the force at the present time. The two 'revenue making' sections of the bill are still held up by a petition referring them to the vote of the people at the coming election. The act appropriated $25,000 to maintain the commission, with the expectation that there would be considerable revenue from fees, but these fees will not be forthcoming until after the election, and if the referred sections are defeated we will get no revenue at all until after the Legislature can meet and amend the act."

Improvements in Schenectady

In accordance with its agreement to extend its lines from Schenectady to South Schenectady and to Carman and through the Grand Boulevard if it were not compelled to sell six tickets for a quarter, the Schenectady (N. Y.) Railway has announced that it will soon proceed to make these improvements. The improvements as estimated at that time, and the estimated cost of the improvements to be made in the next three years follow:

Grand Boulevard and double-tracking of lines in Union and Wendell Avenues and Rugby Road	$206,500
Renewals of present rails and overhead construction	194,700
New emergency carhouse	14,000
New machine shop and equipment	100,000
New substation in McClellan Street	102,430
Block signal systems on three interurban lines	75,000
Six new interurban cars	54,000
Ten trailers for city lines	30,000
Remodeling seventy cars into pay-at-entrance type	42,000
Changes in underground and overhead feeder systems	84,125
Changes incident to widening Lafayette Street	96,100
Total	$998,855

Though the statements of J. F. Hamilton, general manager of the company, provide that these improvements were intended to be made within three years, plans already have been made to extend the lines to suburban districts in the near future. The company has also drafted petitions to be sent to the Schenectady Common Council and to the Town Board of Rotterdam at its next meeting.

Brooklyn Subway Section Contract Let

During the week ended Aug. 22 the Public Service Commission for the First District of New York awarded to the Flinn-O'Rourke Company, Inc., the contract for the construction of Section 3 of Route No. 33, the Montague Street portion of the Whitehall-Montague Street tunnel line in Brooklyn. This firm was the lowest of eight bidders at $3,395,152. The bids ranged from the figure given to a little more than $5,000,000. The contractor must begin work within sixty days after the delivery of the contract and give a bond for $500,000. He will have thirty-six months in which to complete the work. This contract is a continuation of the Whitehall-Montague Street tunnel line for operation by the New York Municipal Railway Corporation, and the same company has the contract for building the tunnel.

The third contract for special work for the Fourth Avenue Subway in Brooklyn has been awarded by the commission.

It covers the supply of switches and frogs for certain portions of that subway. The contract went to the lowest bidder, the Pennsylvania Steel Company at $37,426, for final delivery within 100 days.

The commission has advertised for bids to be opened on Sept. 15, for the construction of Section 2 of Route No. 48, the William Street portion of the Park Place, William and Clark Street Subway to be operated by the Interborough Rapid Transit Company. The plans call for a two track underground railroad to be completed within twenty-eight months from the delivery of the contract.

The Third Avenue Railway has begun operation with storage battery cars of the line from Bartow Station on the New York, New Haven & Hartford Railroad to Belden Point, City Island. Eventually the road will be operated by overhead trolley, but for the present eight storage battery cars are used.

Attempt to Organize Baltimore Employees Fails

The attempt that was made to organize the employees of the United Railways & Electric Company, Baltimore, Md., and precipitate a strike in that city has failed dismally. The men who became affiliated with the union were largely trainmen who had been discharged for cause, and the call for a strike which was issued on Aug. 24 at three o'clock ordered the men to quit their cars at 7 p. m. The attempt to stop service resulted only in delay to the cars and in the arrest of about thirty disorderly persons. On the morning of Aug. 25 practically the full force of motormen and conductors reported for duty. The relations of the company with its employees have always been very friendly. William A. House, president of the company, announced that he considered the attempt to array the men against the company not only adverse to the best interests of both the men and the company, but to the riding public as well. That the relations of the company and the employees were satisfactory, he said, was shown by the loyalty with which the men supported the company.

Municipal Ownership Carried at Pekin, Ill.—The proposition to authorize the city to issue bonds to provide funds to purchase, reconstruct and extend the Pekin & Petersburg Railway in Pekin as a municipal undertaking carried at a special election at Pekin, Ill., on Aug. 21.

Extension of City Line Opened in San Francisco.—The Van Ness Avenue line of the San Francisco (Cal.) Municipal Railways has been placed in operation. The branch is 3½ miles long and extends from Market Street and Van Ness Avenue to the Chestnut Street terminus. Seventeen cars have been placed in service, six of them running the full length of Van Ness Avenue and the other eleven running from the ferry to Geary Street and Van Ness Avenue, thence to the exposition grounds.

War Interferes with West Indian Electrification.—The work of reconstructing and equipping the Bridgeton Tramway, Bridgeton, Barbados, West Indies, with electricity will be postponed for the present on account of the war. The property is owned by William B. McKinley, president of the Illinois Traction System, and his associates, and W. R. Morrison, long connected with McKinley properties, was on his way to Bridgeton and had got as far as New York when war was declared. Contracts for part of the material to be used in the reconstruction had been placed with German manufacturers.

Supplementary Bus Service in Seattle.—The utilities committee of the City Council of Seattle, Wash., has recommended for passage a bill appropriating $25,000 from the city stable bond fund for the purchase of five automobile buses, to be operated by the city to connect Divisions "A" and "C" of the Municipal Railway, and run in opposition to the Seattle, Renton & Southern Railway on Fourth Avenue and the lines of the Puget Sound Traction, Light & Power Company on streets where common user rights cannot be obtained without litigation. Transfers will be issued from the buses to the municipal lines.

Hazleton Strike Declared Off.—The strike of the employees of the Lehigh Transit Company, Hazleton, Pa., which was started on Jan. 1, was declared off by the men on Aug. 22. Three of the thirty-eight strikers, members of the grievance committee, voluntarily withdrew from further consideration in the issue and the company agreed to take all of the others back. The charge made by the company against the grievance committee was that its members broke faith with the company when the strike was declared. References to the strike have appeared in the ELECTRIC RAILWAY JOURNAL of Jan. 24, page 201; April 18, page 894; July 18, page 140, and Aug. 8, page 270.

New York City Franchise Abandoned.—The New York (N. Y.) Railways has filed with the Public Service Commission of the First District of New York a declaration of abandonment of its franchise route over what is known as the Roosevelt Street ferry branch of the Madison Street surface line. The route runs from Roosevelt Street ferry to South Street, to James Slip, New Chambers Street, and to the intersection with Madison Street. The company's application for authority of abandonment states that the board of directors authorized the abandonment on May 6, and on July 1 more than two-thirds of the stockholders and upward of two-thirds of the bondholders ratified the action of the board.

Baseball Game Between the Bangharts and the McWhirters.—The annual baseball game between the Bangharts and the McWhirters occurred at Donnelly's, College Point, L. I., last month. The occasion was the annual outing of the McWhirter-Banghart Relief Association. After the game, at which the McWhirters won, a shore dinner was enjoyed. W. O. Wood, president and general manager of the New York & Queens County Railway, was umpire-in-chief. Among those who distinguished themselves during the game were C. S. Banghart and J. S. McWhirter, captains of the respective teams; Major Evans, H. L. Ransom, C. R. Ellicott, W. R. Kerschner, A. Green, C. W. Wilder, F. A. Elmquist, J. J. Dempsey and A. McIver.

Strike in Maryland.—The motormen and conductors in the employ of the Cumberland & Westernport Electric Railway, Cumberland, Md., went on strike on Aug. 19 to enforce their demands for an increase in wages to a uniform scale of 26 cents an hour. This would mean an increase of 1 cent for motormen and 3 cents for conductors. Ferdinand Williams, president of the company, stated that the company was willing to have the Public Service Commission mediate, were the offer acceptable to the men. He said the men could go to work at once, pending the finding of the commission. He added that the company would be willing to give the increase asked by the men if the receipts warranted it, but that this year's income was less and the expenses greater than last year.

Service Resumed in Vincennes.—An appeal to the Federal Court for an injunction enabled S. S. Bush, Louisville, Ky., operator of the Vincennes (Ind.) Street Railway, to resume operation on the lines in Vincennes. Mr. Bush asked that the order be directed against the striking employees, the members of other unions in Vincennes and the city administration. Under protection of the Federal Court, limited operation was resumed pending the hearing on the temporary injunction in the Federal Court in Indianapolis. Mr. Bush is quoted as follows: "We found it necessary to discharge the old employees because they were unfriendly to the company or were intimidated by threats of violence on the part of outsiders. We are putting other men to work as rapidly as we can, though we are not using professional strike breakers to keep the cars moving."

Stone & Webster Men in the War Zone.—A number of Stone & Webster men were in Europe at the recent beginning of hostilities, but so far as is known, all are now outside the immediate centers of military attack. Charles F. Wallace of the Stone & Webster Management Association returned to Boston recently on the *Finland* from England, and E. N. Lake of the Chicago office of the Stone & Webster Engineering Corporation has arrived in Boston after a voyage from Antwerp. J. F. Manning, Frederick Arnold, W. L. Fales, and Henry Houghton of the Boston office were in England at last accounts, as was George Winthrop Lee, librarian of Stone & Webster, who went to Paris in midsummer to attend an Esperanto conference. Mr. Lee was obliged to leave the city twelve hours after his arrival on account of the mobilization of troops. It is expected that Mr. Lee will sail from England for home within a few days and that Messrs. Arnold and Fales will return via the Italian-Mediterranean lines. J. W. Buzzell of the New York office was last heard from in London.

Financial and Corporate

Recent Financial Tendency

As far as the New York Stock Exchange is concerned the policy of the board of governors of "watchful waiting" continued on Aug. 27. The present is the longest period that the New York exchange has remained closed and is the first time in the history of Lombard Street that the London Exchange has suspended. In the panic of 1873 the New York Exchange was closed for ten days. On Aug. 25 it was reported by cable from London that the London Stock Exchange had appointed a sub-committee to consider the advisability of opening. Many suggestions have been made for opening the New York exchange, among them one that the exchange be opened for domestic trading only, under a rule prohibiting buying and selling American securities for account of foreign investors. The recommendation made by Henry Clews was that the exchange be opened on a given day for a limited period, operations to be confined to four designated active stocks.

Some of the influential commission houses in New York are understood to have urged their clients to buy stocks on the cash basis authorized by the exchange. In this connection the return on a number of principal issues on the basis of the closing prices of July 30 has been pointed out, among them Atchison and Steel preferred returning nearly 7 per cent; Brooklyn Rapid Transit 7½ per cent; Steel common more than 9 per cent and Amalgamated Copper better than 12 per cent, to mention only a few.

On Aug. 25 President de Aguero of the Consolidated Stock Exchange in New York, announced that the resumption of trading was being considered by that body, the plan being to confine transactions within a limited range of prices, the minimum being an average of about one point below the closings of July 30, all trades to be for delivery on the following day and no marginal trading to be allowed. The latter rule would eliminate short selling. What the problems are that attach to reopening are indicated by the more than $100,000,000 of European securities dumped on the American market in the last week of trading in New York. The European market absorbs annually about $300,000,000 of American securities, and no less an authority than Sir George Paish, editor of the *Statist*, London, has estimated that $6,000,000,000 of American securities are owned in Europe.

While the matter of opening the exchanges is an important one, the question which at the time this report was being written caused most concern was that of caring for outstanding foreign indebtedness. As regards the restoration of international credits only moderate progress has been made. The national banks and the trust companies necessarily have taken a position against movements of gold that are not essential. In connection with the question of foreign obligations, the suggestion has been made that a clearing house be established for foreign exchange and that all requests for gold to satisfy legitimate commercial credits be referred to the clearing house and that shipments of gold be permitted only in case of necessity. So far interchange credit arrangements have been worked out with France, Italy, Switzerland and Argentina. London still insists upon being paid in gold, wherever obligations contain a provision for payment in that form, and the effort has thus far proved unavailing which was advocated of allowing money owed in England by corporations and banks in the United States being paid here and drawn against for import. In the meantime exports from the United States, while moving now in considerable volume, are still far below the amount needed to offset American debts in the British capital. The question that confronts a number of American railroads with early maturities is whether any of their obligations about to become due are effected by the English moratorium.

It is generally anticipated that the plan worked out by the National City Bank of establishing South American branches will facilitate our trade and tend to enlarge our commercial field. In this respect the direct banking connections made by the Broadway Trust Company, New York, with Japan is of interest. Heretofore importations to Japan have been made through the instrumentality of bankers of London and other European countries. Letters of credit are already being issued under the new arrangement.

According to *Financial America* the most striking feature of the abstract of the condition of the national banks of the United States as to June 30 last, just published in detail by the comptroller of the currency, was the ability of these institutions to preserve their strength in gold holdings notwithstanding the enormous drain of gold to Europe in the first half of the year. For the six months ended June 30, 1914, the net exports of gold in excess of imports was more than $53,000,000 and yet the banks at the end of the month held in gold coin and gold certificates $625,863,069, compared with $592,759,204 on Jan. 13, 1914, as reflected by the comptroller's exhibit, an actual increase of $33.103,865. Compared with the statement of March 4, 1914. the gold holdings on June 30 last fell only $4,789,906. The explanation is offered that in anticipation of a foreign demand the banks operated their accounts so as to displace gold in circulation with silver certificates, as the holdings of silver dollars and silver certificates declined $23,519.980 from Jan. 13 to March 4, 1914, though there was an increase in silver holdings from March 4 to June 30 of $4,259 740. The reduction in this item from Jan. 13 to June 30, 1914, was $19,260,240. The six months' native production of gold was about $45.000,000, assuming an annual output of $90.000 000 gold for the United States. This figure, coupled with the exchange of silver for the more precious metal in the last six months, would have provided a surplus of about $11,000,000 over the gold exports of $53.000,000 in the half-year.

While in individual cases the losses to American trade have been severe, many of the almost wholesale curtailments reported in the daily papers during the early stages seem to have been greatly exaggerated. In the electrical trade only such adjustments have been made as were concomitant with the unprecedented situation with which manufacturers found themselves confronted. The early reports of wholesale automobile and typewriter retrenchment certainly were greatly exaggerated and the interviews with men prominent in New England industry which have appeared in the Boston *News Bureau* do not bear out the early pessimistic utterances. That the grain and the cotton problems are posers none will deny. The problem that confronts the electric railways is largely one of future financing. For the present, at least, one may expect only such important improvement work to be carried out as has already been financed. While the earnings of American public utility companies will probably not suffer materially, except through cessation in industrial work and the consequent loss of traffic, the tendency to go slow has already manifested itself in the suspension of dividends by a number of companies as a means of harboring resources. The cessation of dividends by the Cities Service Company and the Fonda, Johnstown & Gloversville Railroad has already been noted in these columns, and to these companies are added this week the Portland Railway, Light & Power Company, Portland, Ore., and the Tennessee Railway, Light & Power Company, Memphis, Tenn. Furthermore there is the deferring of action by the trustees of the Chicago Elevated Railways in regard to the expected quarterly dividend on the preferred participating certificates of that company.

The features of the country's foreign trade return for July, made public on Aug. 25, were the new high record for July imports of $160,178.000, and the excess for the month of imports over exports of $6.095,000. July therefore was the fourth consecutive month in which the country's imports have exceeded the exports. Taking the seven completed months ending with July, the export balance stands at only $59.625,000, whereas in the same months last year the exports exceeded imports by $307,907,000. A year ago the July figures showed an export excess of $21.929 000. These figures do not of course cover the period of the European war disturbance except during its preliminary stages in the last week of July.

The emergency shipping bill authorizing the admission of foreign-built ships to American registry was signed by President Wilson on Aug. 22. Regulations under the new law are in course of preparation by the Bureau of Navigation.

ANNUAL REPORTS

New York, New Haven & Hartford Railroad

The New York, New Haven & Hartford Railroad and its associated companies have issued a summarized report of operations for the year ended June 30. In that period the parent company had left, after paying interest and rental charges, only $268,662, as compared to a balance of $8,922,000 reported for 1913. In its introduction to the statements the New Haven says of the net income as reported:

"This represents the amount available for the payment of floating debts, additions, and improvements necessary, but unproductive or only partially productive, such as new stations, and therefore preferably payable out of income rather than from new capital, and for dividends. The fiscal year ended June 30 has been a difficult one for all transportation companies and particularly for those in New England. A summary of the figures shows that the many complications and difficulties to be met by the various properties resulted in balances over fixed charges as follows:

New York, New Haven & Hartford Railroad, surplus	$ 268,662
Central New England Railway, surplus	230,020
New York, Ontario & Western Railway, surplus	663,692
New England Steamship Company, deficit	77,802
Hartford & New York Transportation Company, surplus	85,965
New Bedford, Martha's Vineyard & Nantucket Steamboat Company, surplus	62,708
The Connecticut Company, surplus	1,501,072
The Rhode Island Company, surplus	347,642
Berkshire Street Railway, deficit	72,507
New York & Stamford Railroad Company, deficit	5,824
Westchester Street Railroad, surplus	4,883
New York, Westchester & Boston Railway, deficit	246,923
Housatonic Power Company, surplus	78,506
Westport Water Company, surplus	1,664

"Every property of the New York, New Haven & Hartford Railroad earned its fixed charges except four, including the New England Steamship Company. The Berkshire Street Railroad shows a deficit of $72,507, whereas a year ago the deficit was $91,861, showing an improvement of $19,354. The New York & Stamford Railroad Company reduced a deficit last year of $36,556 to $5,281 this year, showing an improvement of $30,732. The New York, Westchester & Boston Railway (apart from the interest on its bonds and notes) reduced its deficit from $334,554 to $246,923, an improvement of $87,630.

"The statements of income, profit and loss for the New York, New Haven & Hartford Railroad and its subsidiaries are shown in the accompanying table. In connection with these statements the preliminary summary gives the interest of the New York, New Haven & Hartford Railroad in the various subsidiaries as follows: Central New England Railway, 99.8 per cent; New York, Ontario & Western Railway, 50.1 per cent; New England Steamship Company, Hartford & New York Transportation Company, New Bedford, Martha's Vineyard & Nantucket Steamship Company, Connecticut Company, Rhode Island Company, Berkshire Street Railway, New York & Stamford Railway, Westchester Street Railway, Housatonic Power Company and Westport Water Company, sole interest, and New York, Westchester & Boston Railway, 99.6 per cent.

TABLE SHOWING STATEMENTS OF INCOME, PROFIT AND LOSS FOR NEW YORK, NEW HAVEN & HARTFORD RAILROAD AND VARIOUS ELECTRIC RAILWAY SUBSIDIARIES.

*Deficit.

Cleveland Transfer Charge Restored

The report of the Cleveland Railway, made to the directors on Aug. 22, shows the interest account to have been $276,802.05 on Aug. 1. Under the Tayler franchise, the company was entitled to adopt the next higher rate of fare in the fixed scale on that date, but because the figures could not be put into shape until late in August, the higher rate will go into effect on Sept. 1. This change comes about automatically, as the interest fund has dropped below the minimum of $300,000. The rate will now be 3 cents with 1 cent for transfers and no rebate. It will continue until the interest fund reaches $700,000, when it will automatically drop back to the straight 3-cent rate again. The rate taken under the ordinance, however, may not produce a sufficient amount to increase the interest fund to that point and take care of other charges that the company has been compelled to meet. Unless some other plan were adopted, the transfer charge would remain. If found necessary to maintain the interest fund intact a higher rate of fare may be adopted. It is believed, however, that this rate will take care of the expenses and the fund. The charge for transfers is estimated to produce about $800,000 per year.

The monthly reports made by the company for July show the figures based on the ordinance allowances and those based upon actual expenditures, for both 1914 and 1913. These reports are as follows:

Based on Ordinance Allowances

	1914	1913
Operating revenue	$664,869	$629,994
Car mile allowances for maintenance and operation	538,020	487,205
Net operating revenue	$126,849	$142,789
Non-operating income	4,989	1,016
Gross income, less allowances	$131,838	$143,805
Taxes	38,469	38,628
Income, less allowances and taxes	$93,369	$105,177
Interest	142,156	130,369
Deficit	$48,787	$25,192
Special allowances	18,000	......
Net deficit	$66,787	$25,192

Based on Actual Expenses

	1914	1913
Operating revenue	$664,869	$629,994
Maintenance and operating expenses	601,233	485,825
Net operating revenue	$63,636	$144,169
Non-operating income	4,989	1,016
Gross income, less expenses	$68,625	$145,185
Taxes	38,469	38,628
Income, less expenses and taxes	$30,156	$106,557
Interest	142,156	130,369
Deficit	$112,000	$23,812
Obsolete property	12,000	......
Net deficit	$124,000	$23,812

Chicago (Ill.) Elevated Railways.—At the meeting of the trustees of the Chicago Elevated Railways, it was decided to defer action on the declaration of a quarterly dividend of 1½ per cent on the preferred participating shares. Action on the dividend was expected at this time, but no date has been set for any future meeting.

Cincinnati, Lawrenceburg & Aurora Electric Street Railway, Cincinnati, Ohio.—Frank B. Shutts has been appointed receiver of the interests of the Cincinnati, Lawrenceburg & Aurora Electric Street Railway in Indiana. He was appointed receiver of the company in the state of Ohio some time ago.

Cities Service Company, New York, N. Y.—The directors of the Cities Service Company have referred the question of dividends to the executive committee, which will make its recommendation to the board at some future time. Formal announcement was made by the company in the early part of the current month that payment of further cash dividends would be deferred until a reliable forecast could be made of the financial situation and the security markets.

Gary & Interurban Railroad, Gary, Ind.—Willoughby G. Walling recently resigned as trustee of the Gary Connecting Railways and the Gary & Interurban Railway. The directors of the Gary & Interurban Railroad, which is the successor company by consolidation to the above railway, have appointed William P. Abbott to succeed Mr. Walling.

Kansas City Railway & Light Company, Kansas City, Mo.—John B. Dennis, S. L. Fuller, Jerome J. Hanauer and James J. Storrow, composing the committee representing the 6 per cent collateral notes of the Kansas City Railway & Light Company, deposited with the committee at the New York Trust Company under an agreement dated Aug. 15, 1912, announce that interest on the notes from March 1 to Sept. 1, 1914, will be paid on the latter date at the New York Trust Company at the rate of 7 per cent per annum.

Monterey Railway, Light & Power Company, Monterey, Mexico.—The total net earnings of the Monterey Railway, Light & Power Company for 1913 are reported to have amounted to $444,251. After meeting fixed charges and interest on debenture stock and providing for the dividend of 5 per cent on the preferred stock, there remained a balance of $127,251, increasing the surplus brought forward to $601,098, out of which $150,000 has been placed to reserves for contingencies, increasing that fund to $450,000, leaving a credit to profit and loss of $451,098. The loss to the company on account of the disturbed conditions in Mexico is said to be represented principally by diminished earnings. Owing to the unsettled conditions and unknown future, and to the exorbitant rate of exchange upon transfers of money out of Mexico, the directors decided that it would not be in the interest of the holders of the debenture stock to pay the interest due in February, 1914, and a circular to that effect was issued.

Northern Illinois Light & Traction Company, Ottawa, Ill.—The Northern Illinois Light & Traction Company, controlled by the Western Railways & Light Company, reports gross earnings for the year ended June 30, 1914, of $243,207, an increase of $34,505, or 16.53 per cent, over the preceding year. Operating expenses were larger by 9.05 per cent, and net earnings were $115,448, a gain of $23,914, or 26.12 per cent. Interest and other charges were $34,484, an increase of 14.42 per cent, and the surplus, after all charges, was $80,963, a gain of $19,572, or 31.88 per cent.

Pacific Gas & Electric Company, San Francisco, Cal.—As subscriptions have been received for more than 70 per cent of the issue of $12,500,000 of new first preferred stock of the Pacific Gas & Electric Company, the financial plan outlined in a letter to the stockholders under date of June 3, 1914, has been declared operative. Up to Aug. 15 the subscriptions received exceeded $8,750,000 from 3000 subscribers. Many of the subscribers have either paid for their stock in full or have signified their intention of completing the full payment upon allotment, but in view of the disturbed financial conditions the directors have deferred the time of payment of the second installment of $15 a share from Aug. 15 to Oct. 15, of the third installment of $12.50 a share from Oct. 1 to Nov. 15 and of the fourth installment of $12.50 a share from Jan. 1 to Jan. 15, 1915.

Portland Railway, Light & Power Company, Portland, Ore.—In a circular to the stockholders of the Portland Railway, Light & Power Company announcing the passing of the regular quarterly dividend of 1 per cent, which is due at this time and usually payable on Sept. 1, the directors say in part: "The annual report of the company for the year ended Dec. 31, 1913, gave information as to the earnings and financial condition of the company. The figures given showed that the surplus available for dividends upon the stock had been decreasing steadily for two years, owing to business depression, very heavy increase in taxes and increased interest charges. When the report was written on May 1, 1914, it was thought that these unfavorable conditions had about run their course and that gradual improvement might be expected. Up to the present time, unfortunately, the expected improvement has not manifested itself. Under these circumstances, the interests of the stockholders require that the company should conserve its cash resources so as to be prepared for any eventuality, and the directors have accordingly determined to pay no dividend on Sept. 1."

Tennessee Railway, Light & Power Company, Memphis, Tenn.—The directors of the Tennessee Railway, Light & Power Company have decided to defer the usual quarterly dividend payment on the $10,250,000 of 6 per cent cumulative preferred stock. An official statement says in part: "In view of the present unsettled financial and business conditions throughout the world, the board has decided that the only proper policy is to conserve our cash resources in every possible way until the effect of the war is more clearly determined. The regular quarterly dividend on the preferred stock will therefore not be paid on Sept. 1. The dividend of June 1, 1914, was made possible through contributions of the four banking firms which organized the company, without the creation of an obligation of any kind. The earnings during the past year have naturally suffered from the business depression, but it was assumed that with improving conditions due to excellent crops, and the completion of construction work, the company could continue to pay the regular quarterly dividends on the preferred stock. Several large contracts for sale of power were about closed, or under negotiation, and to provide for the increased business expected a contract had been made to purchase a large amount of power from the Brady plant on the Tennessee River, and the construction of the transmission line required for its proper utilization was commenced in May and has just been completed. This will enable us not only to operate most economically, but to take on new power contracts as fast as they can be secured. Owing to the present uncertainty, however, it is impossible to close at this time several large power contracts which were counted on materially to increase the earnings. The retail light and power and the street railway business will depend entirely upon industrial conditions. The company has financed its requirements until June, 1915, when bonds or a note issue must be sold. There would be no difficulty under normal conditions in doing this, but we have no precedents for the present situation, and forecasts of earnings or financial probabilities are of no value. The wise course, therefore, is to keep our cash position as strong as possible."

Washington-Oregon Corporation, Vancouver, Wash.—Federal Judge Cushman at Tacoma has put over until Sept. 21 the question of appointing a permanent receiver for the Washington-Oregon Corporation. The Fidelity Trust Company, Philadelphia, trustee for a mortgage made by the company for $5,000,000, under which $1,563,000 of bonds have been sold, desires to have E. M. Hayden, the temporary receiver, confirmed as the permanent receiver for the railway company.

Dividends Declared

American Railways, Philadelphia, Pa., quarterly, 75 cents, common.

Northern Ohio Traction & Light Company, Akron, Ohio, quarterly, 1¼ per cent, common.

Northern Texas Electric Company, Fort Worth, Tex., 3 per cent, preferred; quarterly, 1¾ per cent, common.

Terre Haute Traction & Light Company, Terre Haute, Ind., 3 per cent, preferred.

Traffic and Transportation

Safety Zones in Louisville

The Louisville (Ky.) police department, in conjunction with the officers of the Louisville Railway, is making a test of the safety zone standards at Fourth and Walnut Streets, perhaps the busiest corner in the city. The moveable standards, with heavy iron pedestals and topped by a red metal flag with the words "Safety Zone" painted on them in white, have been placed on Fourth Street, about 50 ft. from the intersections and between the curbing and the street railway tracks on the sides at which the cars stop to discharge and take on passengers.

Samuel Riddle, superintendent of the Louisville Railway, agreed to co-operate with the police department, and the experiment is being tried out with interest not only to the police but to the owners and users of vehicles. If the trial at Fourth and Walnut Streets proves successful, similar standards will be placed at other busy corners in the retail section of Fourth Street, such as at the Chestnut Street and the Green Street intersections. At other corners the standards will need to be placed only on Fourth Street as that is narrow while the cross streets are exceptionally wide and give room enough for traffic to pass and people to board and leave cars at the same time.

A city ordinance prohibits any vehicle passing a street car which has been stopped to discharge or take on passengers, but the ordinance has been violated, especially on outlying streets where no traffic police are stationed. Recent accidents at downtown corners have prompted the trial of the standards, and, it is said, if they prove desirable, the system may be extended to include the intersection corners and transfer points of the Louisville Railway lines elsewhere in the city than the heart of the business section.

Anticipating a Public Need

The following interesting statement, complimenting the management of the Citizens Traction Company, Oil City, Pa., was contained in the *Democrat* of that city on Aug. 13:

"J. Harvey McClure, general manager of the Citizens' Traction Company, has introduced many changes in the operation of the cars of the company, with other conveniences for patrons, adding largely to the popularity of the service, with a corresponding increase in its patronage, since he assumed the duties of his important position. But there is probably none of these that will be more generally appreciated than that inaugurated yesterday when all of the big open cars running between Oil City and Franklin were furnished with a stool similar to those used by the Pullman Company on its sleepers.

"When the big cars were introduced into Oil City some years ago, each was equipped with a double step, running its full length on each side. The length of the car made it impossible to make the many sharp curves on Oil City's short streets in safety with the double-deck step, hence the lower one was removed. This left the distance from the street to the first step so great that an aged person, or one the least inclined to weight, could not negotiate it with any degree of comfort. Where the patron had passed middle age, getting on or off the car was also attended with considerable personal risk.

"As the cars were used only during the park season, the discomfort of boarding them or disembarking was submitted to without complaint. But Mr. McClure does not wait for complaints before conserving the comfort and safety of the men and women who travel on trolley cars. He gave the matter considerable thought, his inventive ability being stimulated by the new styles in gowns, which candor compels the admission were never designed to permit the wearer to take the high step the cars require. The Pullman stool seems to be the only solution of the problem. It is carried under the front or rear seat of the car and is easily placed when its use is necessary or demanded by a patron. That the device will be popular when it is more generally known that it is available is without question. It will tend to increase the patronage of these cars by ladies of modesty, besides eliminating the present name of the intersection of Sycamore and Center Streets known as 'rubber-neck corner.'"

Pussy-Footed Men Undesirable

At the annual meeting of the American Association of Railroad Superintendents in New York recently a communication was read from F. D. Underwood, president of the Erie Railroad, who was unable to be present. Mr. Underwood said in part:

"A retrospection shows me that I fell far short in all the essential qualifications I now attempt to portray. Even now I should like another chance on a red-hot division to prove I could be a better superintendent than I was.

"A superintendent should not do physical acts that can be done by someone else. The bawling, hauling we old-timers did is unwise from several points of view. A man who is never angry is not an efficient boss; the spur of anger should be concealed, used but to stimulate the stroke—never paraded.

"There are in all walks of life those who bluster, plead, lie and bring pressure from many sources. The processes used to carry their point are ingenious, plausible and persuading. Quietly sidetrack them when sure you are right; never willingly recede from a position that is fair.

"Breaking a rule or doing something outside of the rules is many times an offense to be condoned, provided the offender has brains. His action showed him fearless and perhaps expedient. There are the seeds of a good man in every rebel. Mentally pussy-footed sort of men are not desirable. An argufier—sometimes called a sea lawyer—has his uses.

"Never condemn a measure you want to kill; praise it, tell in how many times and places it would be fine, then put in the local misfit color."

Near-Side Stop in Leavenworth.—The Kansas City-Western Railway instituted the near-side stop in Leavenworth on Aug. 15.

Transfer Hearing in Missouri.—The Public Service Commission of Missouri will meet in Joplin on Sept. 19 to consider requests for broader transfer privileges from the Southwest Missouri Railroad.

Increase in Fare on New York Line.—The International Railway, Buffalo, N. Y., has filed with the Public Service Commission of the Second District of New York notice of a proposed increase in fare between North Tonawanda and La Salle from 10 cents to 15 cents, the increase to be effective on Sept. 15.

Decline in Traffic in Cincinnati.—Application has been made by the Cincinnati (Ohio) Traction Company to Mayor Spiegel and Service Director Fosdick for permission to reduce the service on all lines. The reason advanced is that many factories have laid off part of their forces and that the receipts of the company have declined about $500 a day. Mayor Spiegel has announced that he will take the matter under consideration, but that he will not consent to a reduction in service until an investigation now under way by the city has been completed.

Stopover Privilege Denied.—The Southwest Missouri Railroad, Joplin, Mo., having denied the request of the city that stopover privileges at the city market be granted, Charles A. Patterson, the city commissioner of public utilities and public property, ordered that cars stop at the market. The company refused stopovers because the tickets might be transferred by persons going to the market to others who are bound for destinations farther on the company's line.

Worcester Company Reduces Suburban Fare.—The Worcester (Mass.) Consolidated Street Railway is issuing special tickets which are to be used by passengers of the Worcester and Jefferson division of the company's lines. Under the new arrangement the tickets, used during certain hours of the day, entitle persons to ride between City Hall, Worcester, and the end of the line at Jefferson for 10 cents, or from Jefferson to City Hall. The fare has been 15 cents between Worcester and Jefferson. The tickets are good only between certain hours in the afternoon and in the evening.

New Through Illinois Traction System Service.—The Illinois Traction System, Peoria, Ill., has decided to run its local cars between Peoria and Decatur via Bloomington without change, the same as its limited cars. The running time between Peoria and Bloomington and Bloomington and Decatur will be shortened, and radical changes will be made in the leaving time of trains. An additional late train, which heretofore ran only to Mackinaw, will hereafter be operated through from Bloomington to Peoria. The company is now arranging to handle large crowds during the Illinois State Fair at Springfield and the National Implement and Vehicle Show at Peoria.

Changes in Fare Methods.—The Buffalo & Lake Erie Traction Company, Buffalo, N. Y., has announced that on Sept. 2 the regulation governing the collection of excess fare where fare is paid on cars will be changed to provide that no excess fare will be collected on fares of 10 cents or less; also establishing a new regulation to the effect that the point to point fares in the tariff do not apply to through transportation of passenger in cases where the through fare between the point of boarding and of leaving the car is more than 10 cents. In such cases the through fare will be charged and the regulations governing collection of excess fare will be applied.

Service Complaint in Hannibal.—The city attorney of Hannibal, Mo., has filed a complaint with the Public Service Commission of Missouri against the Hannibal Railway & Electric Company. The commission is asked to issue an order directing the company to provide better equipment; double track its lines on Broadway; provide sufficient cars to care for the traffic in the rush hours; sell tickets in lots at reduced rates, and make extensions which will insure transportation facilities to the northern part of the city. Extensions are asked to the Country Club and Riverside Park and the request is made that the company sell books of six tickets for 25 cents, and books of 100 tickets for $3.75.

Politics in Gary Fare Controversy.—On Aug. 18 the Common Council of Gary, Ind., issued a notice declaring the 3-cent-fare clause of the franchise of the Gary & Interurban Railroad to be in force. The franchise states that after the lines are in operation five years, tickets must be sold eight for a quarter. This clause the company will resist, it is stated, and an appeal will be made to the Public Utilities Commission. Alderman Dwight M. Kinder, Republican candidate for senator, is leading the attack on the company. State Senator Frank N. Gavit, Mr. Kinder's opponent and Progressive candidate for re-election, is president of the railroad. The company has been operating in the morning and evening rush hours for some time past at a 3-cent fare.

Traction Company Not to Transport Intoxicants.—At the last spring local option election in Decatur, Ill., the city went "dry" by a large majority, and the City Council passed an ordinance recently refusing any steam or electric or express company the right to bring any intoxicating liquor into the city. The chief of police called upon the agents of various companies and presented the order of the City Council in writing and demanded a receipt to the effect that the notice had been served. The representative of the Illinois Traction System, the Wabash, the Vandalia and the Cincinnati, Hamilton & Dayton Railroads, and the Adams, Wells-Fargo and America Express Companies complied with the order, but the agent of the Illinois Central declined to receipt for it.

Wreck on Chicago, Ottawa & Peoria Railroad.—A serious wreck occurred on Aug. 22 on the line of the Chicago, Ottawa & Peoria Railroad between Princeton and Joliet, Ill. The cause of the disaster was a broken brake rod on one of the limited interurban cars. The car was making usual schedule time on a straight stretch of track, and when the motorman attempted to stop his car as it approached a curve near Peru, Ill., a brake rod broke, causing the car to take the curve at such speed that it was overturned. After the motorman found his brake inoperative, he reversed his motor, which reduced the speed materially, and as a result the accident was not as serious as might have been expected. Fifteen passengers received injuries sufficient to require hospital attention. The car body, however, was but slightly damaged, it being one of this company's standard arched-roof interurban cars with composite underframe and a wooden superstructure.

Field Day of Beaver Valley Employees.—The third annual field day and picnic of the employees of the Beaver Valley Traction Company, New Brighton, Pa., was held on Aug. 7. For the twenty-nine events of the field meet 224 prizes, consisting of sweaters, clocks, thermos bottles, carving sets, hair brushes, manicure sets, razors, neckties, handkerchiefs, etc., were awarded. After the events on the program were run off supper was served. A number of persons besides employees of the company were invited and attended. They included physicians, members of Councils and other friends of the company throughout the Valley. The employees of the company do not solicit prizes from merchants, as do members of other relief associations throughout the section in which the company operates. Each individual contributes whatever he sees fit to the field day fund, the balance of the amount needed being made up by the company. This year the employees contributed three times the sum donated by the company.

Change in Signs in Louisville.—For many years certain of the Fourth Street cars of the Louisville (Ky.) Railway have continued out to Iroquois Park, which is 4 miles south of the city proper, though included in the city limits. Some of these cars take the Third Avenue route and some the Seventh Street route. These cars have lately been designated by large enameled signs carried on the front end, replacing small wooden signs and reinforcing the small signs in the windows over the motorman's head. Samuel Riddle, superintendent of the company, noted that considerable time was lost and confusion caused because would-be passengers often could not identify cars and had to stop them to inquire of the conductors whither they were bound. Frequently passengers got on the wrong cars. Now, however, the big red signs, appropriately lettered, indicate the cars which take the Third Avenue route and the big black signs the cars that take the Seventh Street route. Both cars run to populous suburban sections with a 5-cent fare, and carry large numbers of passengers to resorts at the edge of the park and to the park itself.

B. R. T. Holds Big Field Day.—An enthusiastically attended athletic field day was held on Aug. 27 by the employees of the Brooklyn Rapid Transit Company at Dexter Park, Brooklyn. Two baseball games were played during the day by teams representing depots of the company. These games form part of a regular series of about ninety games played during the summer by the Brooklyn Rapid Transit baseball league. During the afternoon much interest was shown in the field events and races, the most exciting of which was a relay race between thirteen teams for a loving cup. The events were not confined merely to the employees themselves but were extended to their wives and children, who participated in egg and potato races, while the gastronomic powers of their sons were taxed to the utmost by a pie-eating contest for boys. A collection of forty prizes, including gold-filled watches, rings, cameras, fountain pens and medals was distributed among the winners. Concerts given throughout the day by the regular Brooklyn Rapid Transit brass band added much to the attractiveness of the program. The athletic events were followed by a dance in the evening.

Through Interurban Service in California on 241-Mile Line.—A joint time-table has been agreed upon by the Oakland, Antioch & Eastern Railway, the Northern Electric Railway and the Sacramento & Woodland Railway whereby through service was established on Aug. 24 between Oakland and Chico, Cal. The distance between the cities is 241 miles, of which the Oakland, Antioch & Eastern Railway covers 107 miles and the two other roads the remainder. On one daily through train each way an observation car belonging to the Oakland, Antioch & Eastern Railway will be run, but on other trains than this passengers and freight will be transferred at junction points so that each line will operate only its own equipment. A total of 299 miles, including branch lines, is involved in the chain thus linked together. The cities north of Sacramento which are tapped are Woodland, Gridley, Colusa, Marysville, Oroville and Chico. The three-car trains operating from Oakland as far as Sacramento will have a total seating capacity of 146 and will make this 90.1-mile run on a regular schedule of two hours and fifty-seven minutes, or at an average speed, including stops, of about 30.5 m.p.h.

Personal Mention

Mr. H. G. Williams, assistant chief clerk of the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio, has been advanced to the position of chief clerk of the company.

Mr. John I. Fiscus, inspector on the Sharon branch of the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio, has been made assistant division superintendent of that branch.

Mr. J. B. Stewart, Jr., has been appointed superintendent of freight of the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio, in addition to safety and efficiency engineer.

Mr. Charles C. Beckman, who has been with the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio, many years, has been appointed superintendent of ways and structures of the company.

Mr. M. C. McElligott, chief clerk to Mr. G. J. A. Paul, manager of railways for the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio, has been promoted to superintendent of transportation.

Mr. Thomas Flanigan, superintendent of the local division of the Mahoning & Shenango Railway & Light Company, at Sharon, Pa., has been promoted to division superintendent of the Youngstown & Sharon division.

Mr. Frederick L. Ray, superintendent of motive power of the Louisville (Ky.) Railway, is one of the incorporators of the Ray Manufacturing Company, which will manufacture and market a patented boiler feed regulator.

Mr. Bion J. Arnold and Mr. Walter Fisher, Chicago, who visited Europe this summer to study the terminal stations in large cities, are reported to have arrived safely in London. They are expected back in Chicago on Sept. 1.

Mr. James Compton, who has been master mechanic of the Atchison Railway, Light & Power Company, Atchison, Kan., has been appointed manager of the Omaha & Lincoln Railway & Light Company, Ralston, Neb. Both properties are controlled by the Illinois Traction System.

Mr. George B. Prest has been elected president and a director of the New London & East Lyme Street Railway, New London, Conn., to succeed the late Thomas Hamilton. The New London & East Lyme Street Railway is operated under lease by the Shore Line Electric Railway.

Mr. Alonzo L. Lockwood has been appointed division superintendent of the Niles branch of the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio. He succeeds Arthur P. Newlin, who was killed in an accident on Aug. 14, when he fell under the wheels of a moving car.

Mr. George T. Bradley has been appointed a member of the new Colorado State Public Utilities Commission by Governor Ammons. Mr. Bradley was formerly chairman of the Democratic state central committee. He will serve on the new commission with Mr. A. P. Anderson and Mr. S. S. Kendall, formerly members of the Colorado Railroad Commission.

Mr. Howard S. Butler, who has been assisting Mr. LeRoy T. Harkness, assistant counsel of the Public Service Commission of the First District of New York, in the work of preparing and supervising rapid transit contracts, has been made an assistant counsel. Mr. Edward Riegelman has also been appointed an assistant counsel. Mr. Riegelman has been an assistant corporation counsel in charge of the street opening bureau for Brooklyn.

Mr. R. H. Sperling, retiring general manager of the British Columbia Electric Railway, Vancouver, B. C., was presented recently with a solid gold cigar box suitably engraved and bearing the Sperling family coat-of-arms as a token of esteem from his associates. Mrs. Sperling was the recipient of a diamond ring. The presentation was made by Mr. F. S. Barnard, resident director of the company. Subsequently a farewell banquet was tendered to Mr. Sperling at the Hotel Vancouver by the officials of the company, presided over by Mr. George Kidd, now general manager of the company. Representative officials from all over the company's extensive system were present.

Mr. F. N. Koziell, who was recently appointed chief engineer of the Railway Storage Battery Car Company, New York, began his railway experience with the West End Street Railway, Boston, Mass., after graduating from the Massachusetts Institute of Technology. Later on he was sent to Manaos, Brazil, by Flint, Eddy & Company as superintendent of motive power, line construction and track, and from there was transferred to the Rio de Janeiro (Brazil) tramways as superintendent of motive power. He returned to the United States in 1907 and became superintendent of equipment of the Union Railway, New York. Later he was appointed general manager of two electric lighting properties at Montpelier, Vt. When these properties were taken over by Tenney & Company, Mr. Koziell returned to the Pearson Engineering Corporation, Ltd., and was sent to Barcelona, Spain, as superintendent of motive power of the tramways in that city.

OBITUARY

Charles Alldis, for fifteen years superintendent of the Torrington division of the Connecticut Company, with offices at Burrville, Conn., is dead.

Isaac Newel Barton, railroad builder, died in his home at Flushing, Long Island, recently at the age of eighty years. He retired from active business fourteen years ago. Mr. Barton was the first superintendent of the Harlem Railroad. After serving seventeen years with that company he became general superintendent of the Long Island Railroad. He also was an assistant to Gen. George B. McClellan in the construction of the Atlantic & Great Western Railroad, and later was connected with the Brooklyn Union Elevated and Brooklyn Bridge Railroad.

Charles E. Bonney, formerly of Chicago, died on Aug. 16 at Jacksonville, Fla., where he had resided for the last ten years. Mr. Bonney was born in Peoria, Ill., on Jan. 23, 1858. He entered the traction field in Chicago by building the street railway in West Twenty-second Street. This work was begun in 1895. The company which operated the line was called the West & South Towns Street Railway, but the name was later changed to the Chicago General Railway. After the company was forced into the hands of a receiver in 1900 Mr. Bonney retired from business and removed to Florida.

Charles A. Ricks, secretary and assistant treasurer of the G. C. Kuhlman Car Company, died suddenly at his home in Cleveland on Aug. 24 as a result of heart trouble. Mr. Ricks was born in Massillon, Ohio, and was forty-five years old. He was the son of Judge Ricks, who sat on the bench of the United States Circuit Court when former President Taft was a circuit judge. His first business connection in Cleveland was with the Standard Oil Company. When the Kuhlman Car Company was reorganized about ten years ago he aided in this work and was made secretary and assistant treasurer at the time the property passed into the control of The J. G. Brill Company. Mr. Ricks was a member of the Country, Union and Tavern clubs. He is survived by a widow. The interment was at Massillon.

Mayor Marx Renominated in Detroit

Mayor Oscar B. Marx of Detroit, Mich., has been renominated on the Republican ticket by 10,000 majority over John McVicar. The latter's attack was largely on the ground that Mayor Marx, in perfecting the agreement with the Detroit United Railway in August, 1913, which provides for the sale of seven tickets for a quarter, had betrayed municipal ownership of street railways, to which he was pledged. The charge was denied by the Mayor. F. H. Ingram, the Democratic nominee, has indicated that the municipal ownership will be a leading feature in his campaign against Mr. Marx.

The work of appraising the properties of the Detroit United Railway within Detroit is progressing steadily under the direction of Prof. E. W. Bemis. Some question has been raised as to whether the appraisal would be completed within the time limit, fixed as Oct. 15, but the street railway commission has stated that the report will be forthcoming at this time.

Negotiations are proceeding between the representatives of the interested municipalities and representatives of the London & Lake Erie Railway & Transportation Company, London, Ont., looking to the extension of the company's line from St. Thomas to Aylmer, Ont.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

NEW INCORPORATIONS

***Southern Minnesota Traction Company, St. Paul, Minn.**—Incorporated in Minnesota with a capital stock of $250,000 to acquire and operate steam and electric railways. Incorporators: William D. Mitchell, George Hoke and Wilfred Rumble, all of St. Paul.

***Frederick & Brunswick Railway, Frederick, Md.**—Incorporated with a capital stock of $100,000 to construct an electric railway from Jefferson to Brunswick. It will connect with the main line of the Baltimore & Ohio Railroad at Brunswick and will be about 9 miles long. As soon as it is completed the line will be leased by the Hagerstown & Frederick Railroad. Among the promoters are T. H. Haller, E. L. Coblentz, T. B. Hayward and others identified with the Hagerstown & Frederick Railway.

FRANCHISES

Stockton, Cal.—The Stockton Electric Railroad has received a 50-year franchise to build double-track extensions in San Joaquin County.

Vallejo, Cal.—The Vallejo & Northern Railroad has asked the City Commissioners for an extension of time in which to complete its line in the northern section of Vallejo.

***Pocatello, Idaho.**—J. D. Browning has received a 30-year franchise for a street railway in Pocatello. The franchise provides for one track loop covering both sides of the town and specifies that additional mileage must be built for a period of three years.

Pekin, Ill.—The proposition for a municipally owned street railway and the authority to provide a bond issue to operate the same was carried at a special election held in Pekin on Aug. 21.

Peoria, Ill.—The Peoria Railway has filed a petition with the City Council for the double-tracking of its lines on Pennsylvania Avenue from Jackson Street to Indiana Avenue.

Cedar Rapids, Ia.—At a special election held in Cedar Rapids last week the people voted in favor of the ordinance giving the Waterloo, Cedar Falls & Northern Railway an entrance into Cedar Falls. The franchise gives the company perpetual rights to operate steam trains over some of the streets. The rights to operate electric cars over other streets are for a period of twenty-five years only. The ordinance now goes to the Council for adoption.

Hopkinsville, Ky.—A franchise providing for the construction of an electric railway in Hopkinsville was sold to R. E. Cooper on Aug. 22. [E. R. J., Aug. 15, '14.]

New Orleans, La.—The Thompson ordinance providing for the extension of the Claiborne Avenue line, rerouting of the Levee and Barracks line and the rearrangement of the Dauphin line was introduced in the Commission Council recently. These lines are operated by the New Orleans Railway & Light Company.

Patchogue, N. Y.—The Suffolk Traction Company has petitioned the Public Service Commission of the Second District for permission to build an extension of its line in Bayport and Sayville and for approval of the exercise of a franchise therefor.

North Tonawanda, N. Y.—The International Railway has applied to the Common Council for a new franchise in place of the one granted the Frontier Electric Railway for the construction of the proposed electric railway between Niagara Falls and Buffalo.

***Milwaukie, Ore.**—L. H. Campbell has received a 25-year franchise from the Council for a street railway in Milwaukie. It is stated that this franchise is not altogether for local purposes but that construction of an interurban line eastward from Milwaukie through the Mt. Hood country is contemplated.

Washington, Pa.—The Monongahela, Ellsworth & Washington Railway has received a 60-year franchise from the

Washington Borough Council over certain streets in the borough. The section of the line between Monongahela and Bentleyville is completed. [E. R. J., Aug. 8, '14.]

Dallas, Tex.—The Dallas Northwestern Traction Company has received from the Council six months' additional time in which to begin and complete the construction of 20 miles of track in Dallas. E. P. Turner, Dallas, president. [E. R. J., Aug. 15, '14.]

***Dallas, Tex.**—John T. Jones and associates have received a franchise from the City Commission for a street railway in East Dallas.

Waco, Tex.—The Southwestern Traction Company has filed an application with the County Commissioners of Waco for a right-of-way through incorporated towns south of Waco. [E. R. J., Aug. 1, '14.]

TRACK AND ROADWAY

Edmonton (Alta.) Interurban Railway.—This company will resume operation, with an hourly service, between Edmonton and St. Albert on Oct. 1. It is at present electrifying the line under the supervision of W. T. Woodroofe. It is understood also that negotiations are being carried on between the company and the Edmonton municipality whereby the latter will supply current for the operation of the line.

***Tramways, Ltd., Edmonton, Alta.**—This is a new company formed for the purpose of constructing a railway from Edmonton to Fort Saskatchewan, via Nanao, a distance of 18 miles. This company, together with the Edmonton Interurban Railway, is negotiating with the city with a view to securing running rights to some central point within the city limits. If a tentative agreement can be reached the ratepayers will probably be asked to vote on it.

Penticton, B. C.—In connection with plans for the operation of an electric railway between Oroville and Penticton, the Okanagan Valley Electric & Power Company recently acquired the Oroville electric light plant from the Similkameen Power Company, and will develop the power at Similkameen Falls to the fullest extent.

Fresno (Cal.) Interurban Railroad.—This company announces that it will begin building the second unit of its line between Alvina Heights and Clovis by Sept. 1. The contract for the work has been awarded to Mahoney Brothers. Material for the completion of the line has been ordered. About 2 miles of the line have been placed in operation. [E. R. J., Aug. 1, '14.]

Los Angeles (Cal.) Railway.—This company is extending the East First Street and Brooklyn Avenue line along North Gage Street to the site of its new carhouse. This line will be extended eventually to Eastlake Park.

San Francisco-Oakland Terminal Railways, Oakland, Cal.—This company will spend $475,000 on its mole and wharf on the Oakland side of the bay. Contracts have been signed with the San Francisco Bridge Company for the work. The contract includes dredging, wharf building and mole construction. There will be an elaborate switching system. Track improvements amounting to $200,000 are being completed by this company in and around Oakland. About 50,000 ft. of new track and roadbed have been laid.

Visalia (Cal.) Electric Railroad.—This company will build a 2-mile extension of its line from Rose Station to Elderwood.

Shore Line Electric Railway, New Haven, Conn.—This company has received permission to extend its line from Backus Corner out along the Salem turnpike. The extension will be about one-third of a mile long.

Miami (Fla.) Traction Company.—This company has placed an order with C. C. Atkinson, of Little River, for 7000 ties to be used in the construction of its line. The ties will be laid in solid concrete and will carry 105-lb. girder rails through the business sections of the city and 90-lb. rails on the other streets. Surveys have been begun by this company in Miami. L. D. Llewellyn, Miami, engineer. [E. R. J., Aug. 1, '14.]

Covington & Oxford Street Railway, Covington, Ga.—Work will be begun within the next few weeks by this company on its line between Covington and Oxford. A loop will be built in Oxford.

East St. Louis & Suburban Railway, East St. Louis, Ill.—L. C. Haynes, vice-president of the East St. Louis & Suburban Railway, conferred recently with the president of the Belleville Commercial Club and a committee of East St. Louis business men and agreed to have the interurban cars, which are operated to the Belleville Square, run four blocks farther east on Main Street and to double track this stretch of four blocks.

Rock Falls & Southern Traction Company, Rock Falls, Ill.—Plans are being considered by this company to begin the construction of this line in the fall. The railway will connect Sterling, Ladd, Rock Falls, New Bedford, Tampico, Princeton, Setonville and Kewanee. Andrew S. Goodell, Rock Falls, secretary. [E. R. J., May 30, '14.]

Indianapolis Traction & Terminal Company, Indianapolis, Ind.—It is stated that this company will build an extension this fall on West Tenth Street from Holmes Avenue to Tibbs Avenue.

Kansas City, Kaw Valley & Western Railway, Bonner Springs, Kan.—This company has nearly completed its right-of-way for the extension of the line between Bonner Springs and Lawrence, Kan. Construction on this section, about 21 miles, will begin about Sept. 30 and cars probably will be running in the spring of next year. The company began operation between Kansas City and Bonner Springs, 17 miles, on July 20. Four cars are used at present.

Skowhegan & Shawmut Electric Railway, Fairfield, Maine.—Surveys have been completed by this company for its 12-mile line between Skowhegan and Shawmut, but no plans have been made to begin construction. The greater part of this line will be through private right-of-way. It will connect at Shawmut with the Fairfield & Shawmut Railway, and with the Skowhegan & Madison Railway at Skowhegan.

Hagerstown & Frederick Railway, Frederick, Md.—An extension westward from Hagerstown to the Country Club is being contemplated by this company in the near future.

United Railways & Electric Company, Baltimore, Md.—The Public Service Commission has decided favorably upon the proposal of this company to divert the Emory Grove, Pikesville and Pimlico line into Madison Avenue at Whitelock Street and to make the route as follows: down Madison Avenue to Eutaw Street, to German Street, to South Street, returning over same course in Baltimore.

Salisbury (Md.) Interurban Railway.—Work will probably be begun in the fall by this company on the construction of its electric line to connect Salisbury, Hebron, Tyaskin, Bivalve and Nanticoke, a distance of 30 miles. [E. R. J., April 4, '14.]

Holyoke (Mass.) Street Railway.—This company will spend about $15,000 for the laying of new rails from the Willimansett Bridge through Holyoke.

Billings, Mont.—A. J. Showalter is said to have interested Butte capitalists in a proposition to construct an electric railway between Red Lodge, Bear Creek, Carbon and Stillwater. [E. R. J., May 23, '14.]

Charlotte (N. C.) Electric Railway.—This company is extending the Myers Park line from Queens College to Briar Creek, a distance of about 1 mile.

Jamestown (N. Y.) Street Railway.—Extensive double tracking operations have been begun by the Jamestown Street Railway in West Third Street, the most congested part of the city. It is intended to equip this section of the city with double tracks.

New York, N. Y.—The Public Service Commission has awarded the third contract for special work for the Fourth Avenue Subway. It covers the supply of switches and frogs for certain portions of that subway. The contract went to the lowest bidder, the Pennsylvania Steel Company, at $37,426, for final delivery within 100 days. Bids have recently been advertised by the commission to be opened on Sept. 15, for the construction of Section 2 of Route No. 48, the William Street portion of the Park Place, William and Clark Street Subway to be operated by the Interborough Rapid Transit Company. The plans call for a two-track underground railroad to be completed within 28 months from the delivery of the contract. The Public Service Commission of the First District has awarded to the Flinn-O'Rourke Company, Inc., the contract for the construction of Section 3 of Route No. 33, the Montague Street portion of the Whitehall-Montague Street tunnel line in Brooklyn. This contract is a continuation of the Whitehall-Montague Street tunnel line for operation by the New York Municipal Railway Corporation, and the same company has the contract for building the tunnel.

Toronto, Ont.—Municipalities will vote on Sept. 21 on the question of closing contracts with the Hydro-Electric Power Commission of Ontario to build an electric railway through the Newmarket, Port Perry and Uxbridge districts.

Oregon Electric Railway, Portland, Ore.—The Oregon Electric Railway has been formally invited by the people living between Eugene and Santa Clara to construct an interurban line down the River road, in case of the failure of the Portland, Eugene & Eastern Railroad to do so.

York, Pa.—George B. Wilson, Allan A. Herr and H. S. Williamson are securing right-of-way for an electric railway on the Harrisburg Pike to Long Park and the fair grounds adjoining the park. It is understood that the Conestoga Traction Company will assume the construction of the new line if a certain amount of stock is taken by persons interested in the new company.

Hull (Que.) Electric Company.—Improvements made to the lines of this company between Deschenes and Aylmer are expected to be completed shortly. About 2½ miles of track has been relaid and considerable ballasting has been done.

Nashville (Tenn.) Traction Company.—It is announced that operations of this company's line from the northern boundary of the city near St. Cecilia Academy to the corporation boundary on Lafayette Street will begin on Nov. 1. The company has adopted plans for the extension of the line to Una, but work will not be begun on this strip until the right-of-way recently granted by the County Court can be amended so as to give the line more territory along the road. It is thought probable that the company will obtain its current from the plant at Hale's Bar. [E. R. J., July 18, '14.]

Tacoma, Wash.—Bids will be received by Public Works Commissioner Woods until Sept. 8 for rails for the municipal street railway. A 5 per cent check must accompany the bid.

West Virginia Light & Traction Company, Charleston, W. Va.—This company is in the market for 5 miles of 70 to 80-lb. relaying rails, delivery to be made at Fayette, W. Va.

SHOPS AND BUILDINGS

Edmonton (Alta.) Interurban Railway.—It is stated that this company will erect a carhouse and repair shops at St. Albert.

Indianapolis Traction & Terminal Company, Indianapolis, Ind.—The general contract for the construction of the new carhouse of the Indianapolis Traction & Terminal Company at Highland Avenue and St. Clair Street has been let to W. P. Jungclaus. The F. S. Cannon Company is the architect.

Louisville (Ky.) Railway.—This company has completed the transfer of its equipment from the old shops at Eighteenth and Walnut Streets to the new shops on West Broadway. All the shop work is being done in the new quarters. The old buildings and site are to be offered for sale.

International Railway, Buffalo, N. Y.—This company has filed plans and specifications in Buffalo for the immediate construction of a brick addition to the Hertle Avenue carhouse to cost $20,000. Plans for a new station in Lockport as a terminal for the Buffalo, Lockport & Rochester Railway have been presented to the Aldermen of the city by the International Railway.

POWER HOUSES AND SUBSTATIONS

Pennsylvania Railroad, Philadelphia, Pa.—Braun & Stewart, Philadelphia, have received a contract from the Pennsylvania Railroad for the erection of substations at Bryn Mawr and Paoli in connection with the electrification of the main line to the latter point.

Manufactures and Supplies

ROLLING STOCK

Havana Central Railroad, Havana, Cuba, has ordered six electric cars from the Wason Manufacturing Company.

Buenos Aires (Argentina) Southern Tramways is contemplating the purchase of twenty new cars, inquiries on which have recently been issued.

Albany Southern Railroad, Rensselaer, N. Y., has ordered one express car from the Wason Manufacturing Company. This corrects an item in the ELECTRIC RAILWAY JOURNAL of Aug. 22, in which the name of the car-builder was mentioned incorrectly.

Corpus Christi Street & Interurban Railway, Corpus Christi, Tex., has ordered two single-truck one-man cars from the Cincinnati Car Company, through W. R. Kerschner, its Eastern agent. The order was placed by A. M. Burke, consulting engineer American Properties Company, Wilmington, Del.

Laconia Car Company, Boston, Mass., is building a new type of car which is to be exhibited at the Atlantic City Convention. It is a low center-entrance car seating forty-four passengers. The car, completely equipped, weighs less than 500 lb. per seated passenger. It is a four-wheel car without trucks, but with novel connections to journal pedestals to prevent oscillation. This company is planning to show the car completely equipped with motors and air brakes. Westinghouse motors and HL control have been selected.

TRADE NOTES

Curtain Supply Company, Chicago, Ill., has received an order to equip with Forsyth fixtures and Rex rollers the 228 new cars recently ordered by the Chicago Surface Lines from The J. G. Brill Company.

Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has received an order to equip with control, air brakes and automatic couplers the 100 new subway cars recently ordered by the New York Municipal Railway.

Art Metal Construction Company, Jamestown, N. Y., has appointed E. St. Elmo Lewis as vice-president and general manager, effective Sept. 1. Mr. Lewis has been for the past ten years advertising manager of the Burroughs Adding Machine Company.

Hess-Bright Manufacturing Company, Philadelphia, Pa., is planning to erect a new factory building at its present location on the main line of the Pennsylvania Railroad, Front Street, for the manufacture of its ball-bearings, and is also adding greatly to the machinery equipment in its present buildings.

William Wharton, Jr., & Company, Inc., Philadelphia, Pa., have appointed R. C. Hoffman & Company, Inc., as their representatives for the Southern Atlantic Coast, with main offices in the Continental Building, Baltimore, Md., and an Atlanta, Ga., office in charge of F. McDermott, located in the Candler Building.

Railway Storage Battery Car Company, New York, N. Y., has appointed Lee Klopman, for fifteen years treasurer of the Eugene Dietzgen Company, as general manager. F. N. Koziell, formerly connected with the Pearson Engineering Corporation, Ltd., has been made chief engineer of the Railway Storage Battery Car Company.

Electric Railway Improvement Company, Cleveland, Ohio, has recently leased bonding cars to the following electric railways: Des Moines (Ia.) City Railway, second car; Bell & Jamison, Los Angeles, Cal., second car; Jamestown, Westfield & Northwestern Railroad, Wilkes-Barre & Hazleton Railway, and Shore Line Electric Railway.

Willard Doud, formerly engineer of shop improvements for the Chicago, Burlington & Quincy and Illinois Central Railroads, has completed the engineering work involved in the design, construction and equipment of the new shops of the Belt Railway of Chicago, at Clearing, Ill., and announces the opening of offices at 538 South Dearborn Street, Chicago, for the handling of all matters pertaining to design, construction, equipment and operation of industrial and railroad shops, factories and power plants.

Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has elected J. J. Hanauer, a junior member of the firm of Kuhn, Loeb & Company, as a director of the company to succeed Paul M. Warburg, recently confirmed as a member of the Federal Reserve Board. T. P. Gaylord, formerly district manager at Chicago, has been appointed acting vice-president to succeed H. D. Shute, who has been elected treasurer and assistant secretary of the company, succeeding T. W. Siemon, who resigned to become secretary and treasurer of the Union Switch & Signal Company.

ADVERTISING LITERATURE

Railway & Industrial Engineering Company, Pittsburgh, Pa., has issued a folder describing its Burke Horn Gap lightning arrester.

Dielectric Manufacturing Company, St. Louis, Mo., has issued a folder which contains colored samples of its various interior paint finishes.

Reading Chain-Block Company, Reading, Pa., has issued a catalog describing and illustrating its multiple-gear chain blocks, stationery hoists, jib cranes and steel plate, I-beam and geared trolleys.

Royal Enameling & Manufacturing Company, Chicago, Ill., has issued a catalog describing its porcelain enameled iron signs, which are for use in the electric railway field as guidance and danger signs and other purposes.

M. H. Treadwell Company, Inc., New York, N. Y., has issued a catalog describing the equipment for and containing views of installations of its industrial railways. Another catalog issued by this company describes its two-way dumping cars.

Barrett Manufacturing Company, New York, N. Y., has issued a folder entitled "Another Mile!" which contains a panoramic illustration of the vast plant of the Standard Steel Car Company's Works at Butler, Pa., which extend a mile in length and are equipped with 750,000 sq. ft. of specification roofing manufactured by this company.

Railway Accessories Company, Chicago, Ill., has issued a catalog describing the Wightman mechanically welded rail joint. As shown in the catalog this rail joint has been practically tested by a number of railroads, among which are the following electric railways: Seattle (Wash.) Electric Railway, Portland (Ore.) Railway, Light & Power Company, and Tacoma (Wash.) Railway & Power Company. Testimonial letters from these companies are quoted in the catalog.

Prepayment Car Sales Company, New York, N. Y., has issued a strikingly colored folder entitled "Origin and Development of Prepaying on Street Cars." The prepayment idea (on street cars) is declared to have been originated by Messrs. Ross and MacDonald and was later developed by the Prepayment Car Sales Company. The prepayment idea was developed on the theory that a small minority of the public are willing to appropriate anything to themselves without pay. The folder calls attention to the fact that though a "free ride" does not seem to be a very heinous crime to the perpetrator, yet enough free rides would wreck the richest railway in the world. The value of the prepayment car is shown in that it prevents accidents and continual accident claims and also checks the free rider.

C-A-Wood-Preserver Company, St. Louis, Mo., has issued a folder entitled "The Third Degree," which contains a declaration that the manufacturers will furnish to every purchaser a sworn analysis of their wood preserver, together with a blank affidavit to be executed by the seller offering his product in competition. This company has also issued a sheet containing information relative to comparative tests of its wood preserver and other similar preparations. A chart attached to the sheet which was prepared by the U. S. Forest Products Laboratory shows that in a test made a cubic foot of wood absorbed 13.45 lb. of coal-tar creosote and 15.1 lb. of wood preserver, and that in a twelve weeks' open test the wood treated with creosote lost 22.42 per cent in weight, while wood treated with the wood preserver of this company lost only three-tenths of 1 per cent.

Trolley Supply Company, Canton, Ohio, has issued a folder describing its roller-bearing trolley base, which is designed to prevent trolley wheels from jumping. The higher the pole goes up the more tension there is against the wire, and the tension decreases as the pole goes down. The lowest tension occurs when the pole is hooked to the roof of the car. This arrangement makes it easy for the conductor to pull the trolley pole down when desired. Another catalog has recently been issued by this company describing and illustrating its trolley supplies, including Knutson trolley retrievers Nos. 2 and 5 for high-speed roads, "Ideal" trolley catcher, simplex roller-bearing trolley base, Peerless roller-bearing trolley base No. 10, Peerless check valve and Junior headlight, pressed-steel headlight, Hollis safety fender, and detachable fender. In the Knutson No. 5 trolley retriever, the same retrieving mechanism is used as in the No. 2, but the opening of the case is enlarged and the method of connecting the rope to reel by means of a chain, screw eye, ferrule and rivet is eliminated. A knot is tied in the end of the rope, which is inserted in a slot in the reel. By inserting the knot it releases the knot pawl and throws the weak spring in action. Should the rope break while the retriever is in action, it would not be necessary to remove it from the car to replace the rope, as the operator himself can do this in a few minutes simply by tying a knot in the rope and inserting it in the reel.

NEW PUBLICATIONS

Traffic Glossary. By R. E. Riley. La Salle Extension University, Chicago, Ill. Paper bound, 136 pages, $1, postpaid.

In the study of interstate commerce and general railway traffic many terms of a technical nature are used for which in the past it has been difficult to obtain convenient, reliable and clear definitions. This traffic glossary prepared for La Salle Extension University should be of material aid in supplying this need. The book is divided into four sections covering the following points: Definitions of traffic territories, definitions of traffic terms and provisions, application of classifications and suggestive questions. Such problems as the meaning of western termini, S.U.L.C.L. (set up in less than car-loads) or reciprocal demurrage can easily be solved by reference to the glossary. It is realized, of course, that territorial definitions are supplemented and superseded from time to time, and where the actual movement of traffic is involved the glossary must naturally give way to the latest official publications on the subject. For general information concerning technical traffic terms and interpretation of abbreviations, however, the glossary serves as a convenient reference book.

Business Administration. By Edward D. Jones. The Engineering Magazine Company, New York, N. Y. 5 in. x 7½ in. Bound in cloth, 275 pages, $2.

In the belief that the administration of manufacturing and operating companies under modern conditions is developing into a new profession, the author of this book has sought its scientific principles by a study of the older professions with which it is most closely allied. His argument is briefly that success in dealing with men and affairs depends upon certain basic laws which can be discovered by studying the work of successful administrators, that the rules and methods followed by masters of business and finance are usually deliberately hidden with no records throwing full light on their lives and acts, but that leaders in stage craft, war and science are figures of world-wide interest, whose career and practice are fully illumined by public and private records, correspondence and personal reminiscences. From such data as these Professor Jones has analyzed different primary principles of administration. In history and the biographies of military conquerors, diplomats and scientists he finds the elementary rules of success.

It has sometimes been stated that the study of scientific management may direct itself to machines, materials, methods and men. Heretofore the first force of scientific management investigation has been expended along the lines of the first three items. It is being realized more and more at present, however, that the human factor is the one of superlatively high rank. For this reason the present book is very interesting, for it examines the best thought of the world to find out how great statesmen and generals have worked with the human beings under their control. The plea of the author in general is for the conduct of modern industrial life in harmony with modern thinking, and it must be said that his treatment of the subject tends to raise administration to a higher plane among the profession than heretofore.

Electric Railway Journal

Published by the McGraw Publishing Company, Inc.

Vol. XLIV NEW YORK, SATURDAY, SEPTEMBER 5, 1914 No. 10

WANTED— A PURE PRODUCTS LAW

Although several states and the national government have laws relating to the purity of foods and drugs, nothing has been done, so far as we know, toward securing a standard of purity in such items as paints, varnishes, insulating compounds and wood preservatives. All of these classes of material are highly complex chemical and physical aggregates, which cannot be graded in the order of merit as empirically as pieces of timber. The buyer is expected to take for granted the word of the purveyor that the materials are of standard purity and proper combination. To-day the only remedy open to the careful purchaser is to subject specimens of the offered materials to some recognized testing laboratory which can assure him whether the goods are adulterated. Such tests for purity are no reflection on the great body of honest manufacturers, but they are a necessary precaution against the temptations of the adulterator with his alluringly low prices. Although a buyer can protect himself adequately through laboratory help it is a pity that he should not receive adequate protection under a law which would make adulteration practically impossible. We do not mean that a manufacturer should be forced to reveal the exact quantitative and qualitative analyses of his products. He should be obliged, however, to state the names of the ingredients together with other data which would indicate the limitations of the product, such as a wood preservative's distillates at different temperatures. Drastic legislation would make it unnecessary to test articles simply for purity, but there is still left a profitable field for testing materials as to their suitability for any given set of conditions.

ELECTRIFICATION IN THE POLAR ZONE

An old writer on biology once noted that the hog and man were the most adaptable of animals, for they prospered in every zone from the torrid to the frigid. The electric railway is not an animal, but the story of the Kiruna-Riksgraensen electrification, as related elsewhere in this issue, entitles it to lay claim to an equally high degree of adaptability. Although located in a land where snow is present during eight to nine months a year, this short railway carried in 1913 some 3,000,000 tons of the famous Swedish steel. Under steam single-track operation, the capacity of the road was approaching its limit. The climatic and physiographic conditions would have made double-tracking for the desired capacity to 5,000,000 tons a year a most costly proposition, and since abundant water-power was available, electrification was merely a matter of a reliable contact system. It is therefore interesting to observe that a simple catenary line with A-frame poles spaced 172 ft. apart should have been considered ample for the greater part of this arctic installation. The contact system differs only in a few particulars from much of the standard European single-phase construction for temperate zones. Thus, sectionalization has been employed to an unusual extent to facilitate the location of defective insulators, and single, though larger, insulators have replaced the double insulators common in more populous regions. The swiveling bracket construction which helps to take care of temperature variations is also an interesting feature of the catenary line. On the whole, the simplicity of the construction is a noticeable feature of this line which has to meet the problem of high-tension distribution under most arduous climatic conditions.

INTERNATIONAL CONVENTION ABANDONED

This week the convention of the International Street & Interurban Association was to have been held in Budapest, but it is, of course, indefinitely postponed. Several advance papers were received in this office last month, evidently having been mailed before the outbreak of hostilities, and are on such up-to-date subjects as rail corrugation, registration and cancellation of tickets, relative advantages of a.c. and d.c. for railways, roller bearings and ball bearings, etc. Instead of the benefit which would result from international discussions on matters of this kind, a pall has fallen over Europe. Even an official notification of the cancellation of the International convention has not been received in this country. The last direct report from our Budapest correspondent, who was to report the convention for this paper, was written on July 27. It simply said that matters then looked unsettled and the convention might have to be postponed. In the meantime, reports received from Brussels, the headquarters of the association, are that the Germans were commandeering the receipts of the Brussels Tramway Company, and, in consequence the company had begun to carry passengers without charge. One of the most unfortunate results of the present war is the inevitable cessation both during war operations and for a long time afterward of a great deal of the valuable pioneer work and investigation in electric railway operation which has been conducted in Europe. We owe a great deal, in the science of electric railroading, to our confrères in all of the nations now at war, but it is vain to assume that much will be done by them to advance electric railway science for years.

The energies of all will have to be devoted to restoring civilization, and to making up, as far as possible, for the immense losses caused by the destruction of property and life. Therefore upon those nations not at war must fall the duty of developing and advancing the art.

CONSERVATION OF CASH RESOURCES

One way in which the present unsettled state of business and finance throughout the world, brought about by the European war, has manifested itself in this country, is through the deferring of corporate dividends. It is estimated that during the last month American companies with $300,000,000 capital have been transferred from the dividend-paying to the non-dividend-paying list, with an annual decrease in dividends of nearly $15,000,000. This suspension of dividends, however, is not entirely a product of the present war situation, for the general financial depression in this country for the past year and a half has also had its effect. It is estimated that since Jan. 1, 1913, stockholders have suffered a loss of revenue aggregating $75,000,000 a year, and according to the *Wall Street Journal*, in the last twenty months dividends have been either passed or reduced by more than 100 of the larger companies, of which seventeen were railroad, eight electric railways and the others industrials. In view of the generally recognized stability of public utility earnings, it is not surprising that electric railways should be at the bottom of this list. In spite of this fact, however, the recent deferring of dividends by the Cities Service Company, the Fonda, Johnstown & Gloversville Railroad, the Portland Railway, Light & Power Company, the Tennessee Railway, Light & Power Company and the Chicago Elevated Railways has caused a slight apprehension among all public utility stockholders. It can be said emphatically that the greater portion of this fear is altogether baseless.

In almost all cases the suspension of dividends has been accompanied by the statement that the reason impelling the action has been the desire to conserve the cash resources or working capital of the corporation. Now, in general, the amount of actual cash needed by a corporation varies with the size of its payroll and other current demands for cash, with the amount and character of its accounts and bills payable in connection with its accounts and bills receivable, with the discounts obtainable by making cash payments and with its facilities for securing temporary loans. These points are of much more vital concern to industrial than to public utilities. The reason is that public service corporations have no turnover where a large amount of capital must be sunk into the product and where there must be sufficient capital to keep the company going, perhaps in the face of slackening trade, until cash is ultimately received for the goods. There is a generally well-defined regularity of demand for the service of electric railways, and the payment for the commodity offered is not deferred. Electric railways secure their passenger revenue daily and thus have a more constant influx and replenishment of their cash assets.

While it appears, then, that public utilities usually need comparatively little working capital, yet it must be said that under certain conditions the problem of adequate current resources is not one of which they are entirely devoid. Through some extra large current liabilities falling due, through some drain on the current revenues, such as strikes or long-continued storm blockades, or through a steady increase in operating costs owing to higher prices for materials and higher wage scales, the railway may find its working capital seriously depleted. A more common difficulty, however, is that exemplified by some of the railways now deferring dividends. The Cities Service Company is in a developmental stage and is constantly in need of new financing for improvements, betterments, additions and the like. Moreover, the company has interested foreign capital in its securities, but this is now withdrawn at a time when financing in this country is difficult. The Tennessee Railway, Light & Power Company is also at an early stage of its growth. It has financed all its requirements until June, 1915, when bonds or a note issue must be sold. Under normal conditions, no difficulty would arise in effecting such a sale, but at present the free disbursement of dividends based on forecasts of easy financial probabilities next year is hardly desirable. The Portland Railway, Light & Power Company is confronted with the problem of raising large sums each year to carry out the requirements of its franchises, many expenditures being inevitable under municipal direction. With the maturing of a $5,000,000 note issue on May 1, 1915, and also of paving assessments for previous work done, and with a record of increased taxes and interest charges and a business depression for two years, it is evident that the company is confronted with conditions requiring close attention to its present working resources.

Such cases as the above, however, are the exception and not the rule. Practically all instances where dividends have been passed, deferred, paid in scrip or reduced have been those of companies confronted with some special or peculiar difficulty during a stringent period when the exercise of corporate prudence made necessary the conservation of all liquid resources. Those companies that are provided with strong working capital, as judged by the requirements of the electric railway field, and are not confronted with the imperative need of financing in the immediate future, are paying their usual dividends. Stockholders may rest assured that a possible impairment of corporate credit through an unnecessary suspension of dividends is too great a danger to run at this time. Even in England, in spite of the present crisis, *The Electrical Review* of London warns firms against refraining from distributing dividends, and that such a measure of precaution might be disastrous to the shareholders. Business here may fall off on account of the war in some cases, as with the factory traffic of the Chicago Elevated Railways, but unless national and world financial conditions become much worse, most companies will not be at all justified in passing their dividends or reducing their dividend rates.

CORROSION OF ALL-STEEL CARS

A prominent designer of permanent structures, in commenting upon a recent editorial on the subject of side sheathing for steel cars, has stated that a 1/16-in. sheet is too thin for practical purposes, pointing out that in ordinary structural design it has become a rule to use sections not thinner than ¼-in. to withstand corrosion successfully. Corrosion of the members of steel cars has, however, by no means the importance that it has in permament structures. The latter are at all times exposed to the action of the elements. Examinations are often cursory in character, and paint is applied more often with regard to economy than to complete protective action.

Certainly it is never the case for a permanent structure to be subjected to the elaborate painting processes that are the rule with passenger cars, and the fact that such paint is applied for the purpose of improving the appearance of the car is a practical guarantee that corrosion is not going to begin at the outside of the structure. Corrosion of the floor framing is, of course, a possibility, for this is never painted with the same care that is devoted to the sides of the car, but these members in modern designs are generally easy of access, and parts of them, in fact, are affected by the same conditions due to flying oil that have permitted many roads to stop altogether the painting of the trucks.

From the inside of the car there is, however, an ever-present tendency toward corrosion, owing to the occasional use of water for car washing. That this must tend to rust the side sheets and posts at the floor line cannot be denied, and when the protective covering of paint breaks down it must be renewed if deterioration is to be avoided, even though there is no evidence that the deterioration will be any more rapid in action than that caused by the rotting which occurs from the same cause at the bottoms of wooden posts. However, if this interior rusting is allowed to go unchecked it would seem to make little difference whether the side sheathing was 1/16 in. or ⅛ in. in thickness. Once the corrosion was well established it would be only a comparatively short time before the sheet would have to be renewed, and while the labor involved would be trifling the expense with a large number of cars might become heavy.

The most obvious remedy is to keep the inside of the side sheathing well painted, and this is certainly preferable to the alternative of using an unnecessarily heavy side sheet which is not only costly to install but involves a continual cost for the energy required to haul the additional weight. To this end the use of an easily-removable inside lining has been suggested, although the use of no inside lining at all would be preferable and is entirely feasible except, perhaps, in very cold climates. Now that the drop sash has practically disappeared the original necessity for using a heavy and permanent inside lining has become solely a matter of custom, the requirements being only those involved by insulation, as the appearance of such a thoroughly inconspicuous surface is hardly important.

WELDING AND TRACK REPAIRS

During the past two or three years the portable welding outfit has come to play a very important part in electric railway track repairs. While many companies have taken advantage of this new means of obtaining renewed life in track, others, either due to a lack of information or because they are not progressive, have looked askance at this method of making repairs. Recently it has been our privilege to inspect track repaired in this manner in a number of large cities and by different methods of welding, and we feel convinced that the plan is an unquestionable success. While some companies have obtained better results than others, the unsatisfactory work may be attributed principally to the failure to employ an intelligent operator. Successful welding is the result of real scientific study, therefore it cannot be properly done by rule of thumb or "cut and try" methods. It is a study in itself, hence the work of welding should be in the charge of not only an intelligent operator but one who is especially interested in the subject. If in the welding process certain things occur which result in the success or failure of the repair, the operator should know why so that he can apply this information in his future work.

Probably most welders have found their principal trouble in trying to restore manganese inserts and solid manganese pieces. While the inherent characteristics of this metal do not make it especially fitted for repairs by any welding process, yet certain precautions taken during the welding operation make it possible to obtain a large proportion of successful welds. For instance, it has been found that if the portion restored is large and the operation is made continuous, the weld usually is unsuccessful. On the other hand, if the restored work is quenched frequently during the welding operation so that no part of the body casting is heated to a critical temperature, success usually follows. Again it is found impossible to make metals of different characteristics bond, principally because of the shrinkage strains which break down the bond when the work cools. Manufacturers of welding outfits have studied this problem carefully and recommend the use of certain metals for certain kinds of repairs. While it may be possible to purchase these metals locally, it is well to have a thorough knowledge of the proper chemical analysis if one desires to obtain best results.

Some operators believe that the finished work should be ground to surface, while others believe that the work should be done under traffic and left in the rough when complete. The latter class believes that welds made under traffic are more compact and homogeneous and that a good operator can do the work sufficiently accurate to make grinding unnecessary. Built-up welds are being made at cupped joints, at chipped intersecting flangeways and at other badly worn points. In fact, many pieces have been restored which otherwise would have required renewal at the time the repair was made. Even if the percentage of unsuccessful repairs is quite large, the cost of making them is so small that as a whole the work undoubtedly will figure as an economy.

MUNICIPAL OWNERSHIP IN LONDON

The perennial question of tramway versus motor bus has again come to the foreground in connection with the London County Council Tramways. As noted elsewhere in this issue, the operating report for the year 1913-1914 shows the financial condition of the tramways to be more hopelessly involved than ever. The anticipation of a surplus of £43,399, as expressed in the 1913 report, has not been realized, there being instead a deficit of £88,526. During the year the actual increase in income was only £16,939, while the operating expenses increased £102,790. Moreover, in spite of increasing withdrawals from the renewals fund, during the year the additions to the fund decreased from the £497 of the year previous to nothing at all, whereas if a full provision had been made for renewals on the agreed basis of two-thirds of a penny per car mile for five years the fund would have received more than £160,000. It is needless to say that the renewals fund cannot long continue unless its depletion is met and remedied in some way. Furthermore, it is estimated that the general fund of the company will have decreased 57 per cent during the two years ending March 11, 1915.

These data are sufficiently interesting in themselves, but similar ones have been previously commented on in these columns. The most striking point in connection with present operating conditions has to do with current English editorial comment. Most of the blame is laid on the power of motor bus competition, but *The Electrician* states that the fault lies in the company's double policy of endeavoring to run the undertaking on a commercial basis and at the same time conducting it for the benefit of certain sections of the community. As we pointed out recently in connection with municipal railway operation in San Francisco, the use of railways as forerunners of urban development may be excellent from the point of view of city congestion, but it does not tend toward satisfactory commercial results. Furthermore, our British contemporary calls attention to the fact that recent concessions to employees have involved expenditures of £14,388 and that demands now made in the face of the present deficit would necessitate the spending of £90,000 more. Nothing could show better than this the political power that the employees of a municipally operated railway may bring to bear on the local legislative body.

The Engineer believes that "had the tramways been run from the first as a business concern by business men the present position would never have been reached. The highways committee forgets in complaining about motor omnibus competition that the tramways when first introduced affected the incomes of certain railroads. One railroad very successfully met competition by electrification and business economy." It is true that business principles and scientific management are not and never have been innate or even acquired attributes of government ownership. But if the difficulties are not due to faulty direction but to conditions which could not have been foreseen, they present an equally strong argument against municipal ownership. As we have many times declared, the electric railway business presents many hazards, some of which may be escaped by good management and some may not. Certainly these hazards are greatly increased by municipal ownership, while the opportunities for escaping those which are common to both public and private ownership are greatly lessened when the city operates the railways.

The only safe plan is for the municipality to refrain from all commercial undertakings possible. The funds which a city can invest in enterprises of this kind are essentially "trust funds," and it should be as careful of exposing them to the hazards of ordinary business as are the administrators of other trust funds. When to this argument is added the demonstrated fact that a municipal enterprise cannot be conducted as efficiently as one under private direction, the inadvisability of municipal operation of electric railway systems is evident.

RAILROAD PASSENGER FARE INCREASE

We know of nothing that has happened for a long time which is more important to the interurban electric roads of this country than the announcement made this week that the Pennsylvania Railroad intends to increase its passenger mileage rate for mileage books from 2 cents to 2¼ cents, and the subsequent statements that nine other steam railroads are planning to take similar action. In explanation of its increased passenger rates the Pennsylvania Railroad says, briefly, that it is due to the increased cost of operation and refers to the greater use of steel cars, the more general adoption of automatic signals and other safety apparatus, the general cost of materials and the higher wages of trainmen which have been characteristic of the last few years.

Facing such a condition and confronted with the half-hearted and only partial grant of increased freight rates recently made by the Interstate Commerce Commission, it is not surprising that the steam lines have followed out the suggestion then made by the commission in the rate decision that they might well consider an increase in their passenger fares rather than devote all of their attention to seeking higher rates for freight.

The connection between this proposed passenger rate increase on steam railroads and the interurban electric railway interests in the country is not difficult to see. For years most of the long interurban electric railroads have been charging fares which are too low—certainly under present conditions. They have been prevented from raising their rates by a number of factors, among which public opinion and steam railroad competition have been perhaps the most important. Now, however, on the initiative of the steam lines, both of these factors will be removed. The public will not fail to recognize that the conditions of higher operating costs of which the steam railroads complain apply to the electric roads as well and they are equally as much entitled to an increase in rates. From a competitive standpoint, also, the electric roads will be able to make an increase of ¼ cent per mile without altering the respective positions of existing steam and electric fares. There will be this difference, however, in which the electric roads will be the gainers. On the average steam railroad of the country, according to the statistics of the Interstate Commerce Commission, the passenger receipts amount to only 20 per cent of the gross, so that an increase in passenger receipts of 12½ per cent, or that accomplished if all of the passenger fares were increased in the same proportion as the mileage fares, would increase the gross receipts only 2½ per cent. But on the electric road, where the business is almost exclusively passenger, the gross would increase in almost the same ratio as the passenger receipts. That is to say, the electric roads ought to benefit almost five times as much as the steam railroads with such a parallel increase in passenger rates.

We do not mean to say that such increase on both lines, even though justified and though supported by the prestige of the Interstate Commerce Commission, will not meet some obstacles. This will have to be expected. An increase in mileage rates will necessitate an increase in many local rates, and this may not only create much local opposition but involve a rate in excess of that permitted by state law. However, the tendency in rate making is constantly to vest more power in the federal authorities, and with the Shreveport decision as a precedent we do not believe that such local rate-making statutes will be allowed by the federal courts to interfere with the rates deemed just by the Interstate Commerce Commission.

If the action by the steam railroads this week should be instrumental in increasing the rates of the interurban electric railways it will prove a boon to the industry.

WHAT DO WE KNOW ABOUT ELECTROLYSIS MITIGATION?

The control of the return currents in electric railway circuits is different from ordinary engineering undertakings because it involves so many variables, several of which are somewhat indeterminate. To illustrate the complex character of the calculations involved, those required in electrolysis investigation need merely to be compared with those involved in the design of a bridge. In the one case we are dealing with definite forces; in the other case with forces and quantities for the most part indefinite and vague. Electrolysis calculations are even much more complicated and uncertain than those associated with inductive interference from single-phase railways to which so much attention has been given of late. Not only are the underlying facts difficult to determine in the case of electrolysis, but there is a conflict of interest and responsibilities. If electrolysis mitigation could be reduced to a science much of the present uncertainty could be avoided.

Of course there is a basis for a complete science of the subject. A large amount of experimentation has been done, especially along the line of measuring the electrical and other quantities involved, namely, current in rails, current in pipes, emf between rails and other conducting structures, and the corrosive effect of current on various metals and in various soils. Various remedies have also been suggested. This was clearly explained in the report of the committee on electrolysis of the American Electric Railway Engineering Association presented last fall. The fact that this committee made no recommendations is indicative of the further fact that the time was not considered propitious for such action. The present situation can be summed up in the statement that while there is general agreement now as to the nature of the disease and its diagnosis, the experts are far from being unanimous as to the remedy to be applied. In other words, the present is a period of "watchful waiting" in the expectation that those commissioned to formulate recommendations will address themselves earnestly to the task.

This paper has been fortunate in securing, during the past few months, a number of articles containing information of a distinctively constructive character. The general tendency of the writers has been to favor the insulated return feeder system. This is done also in the article in this issue by I. W. Gross. While the use of insulated negative feeders is by no means new, the plan has only recently attracted much attention in this country. It is inherently an attractive proposition because it lends itself readily to calculation. As soon as it is determined that a certain rail drop will not cause electrolysis, then comparatively simple electrical calculations suffice to determine the size and location of the proper negative feeders. The plan is also attractive from the standpoint of operation in that all of the measurements needed to show the condition of the return system can be made readily.

On the other hand, all of the installations of the return feeder systems made up to this time have been on a small scale or under very favorable circumstances. Whether the different conditions presented by large surface railway systems would render the system less desirable in such cases remains to be determined. It is not difficult to see that the troubles with the return feeder system will increase rapidly if there is considerable metal in the streets, consisting in part perhaps of uninsulated return feeders and ground connections installed for railway use in the early days. It is also easy to understand that the cost of the return feeder system would increase rapidly with the number of cars operated by the railway. Still more serious might be the effect of the rerouting of a city system upon the return-feeder layout, which would have to be readjusted to suit each alteration of the routes and schedules. For these reasons we can, as yet, regard the insulated return feeder scheme as only one of several remedies for wandering ground currents. The determination of its exact place among the other means for prevention is one of the tasks properly falling to the committee on electrolysis of the American Electric Railway Association.

Building an Electric Railway Within the Polar Circle

Electricity at 15,000 Volts Single Phase Was Adopted to Increase the Capacity of the Kiruna-Riksgränsen Railway Without Double-Tracking—This Article Describes the Equipment and Unique Conditions Under Which This Ore-Handling Railway Was Built

In two recent issues of *Elektrische Kraftbetriebe und Bahnen*, F. Zolland, engineer at Kiruna, describes the construction of the Kiruna-Riksgränsen Railway which is notable as the first electrification within the polar zone. In 1910 the Swedish government determined to electrify the Kiruna-Riksgränsen section of its standard-gage lines between the port of Lulea on the Gulf of Bothnia and Riksgränsen, the latter name signifying the location of the border line between Sweden and Norway. The Norwegian section of the line ends at Narvik on the Atlantic coast. Practically the sole freight business is that of transporting iron ore. Three million tons were hauled by steam in 1913, but as it was desired to raise the output to 5,000,000 tons a year electrification was adopted in preference to partial double-tracking. Electrification will eliminate smoke in tunnels and permit heavier trains and higher average speeds. The present steam trains comprise twenty-eight 11-ton cars capable of carrying 35 tons each while electric trains will have forty cars. The maximum speed of steam trains is 24.8 m.p.h. on level track and 7.4 m.p.h. on 1 per cent grades; the electric speeds for corresponding conditions will be 31 m.p.h. and 18.6 m.p.h. On the whole, the average speed of the trains will be raised about 25 per cent. The large amount of water power and the scarcity of coal were also important economic factors in choosing electrification.

Single phase was adopted owing to the length of the line and the large amount of energy to be transmitted. The transmission potential is 80,000 volts while the contact line carries 15,000 volts at fifteen cycles.

GEOGRAPHICAL AND CLIMATIC CONDITIONS

The extreme northern location of this railway naturally makes its electrification exceptionally interesting. Kiruna, the starting point of the electrification, is about 87 miles north of the polar circle. The lowest recorded temperature here is 52 deg. Cent. below zero. During January and February 25 deg. to 35 deg. below zero are considered normal temperatures. From October until the beginning of May the temperature rises little above zero, and snow is almost always in sight. Owing to the extreme dryness of the atmosphere these temperatures are not severe except when the wind velocities are high. An unpleasant accompaniment of warm weather is the large number of midges and mosquitos.

POLAR ZONE RAILWAY—SINGLE-TRACK CONSTRUCTION AT A POLE CARRYING A SECTION BREAKER

June, July and August are the only months during which frost is usually absent at night.

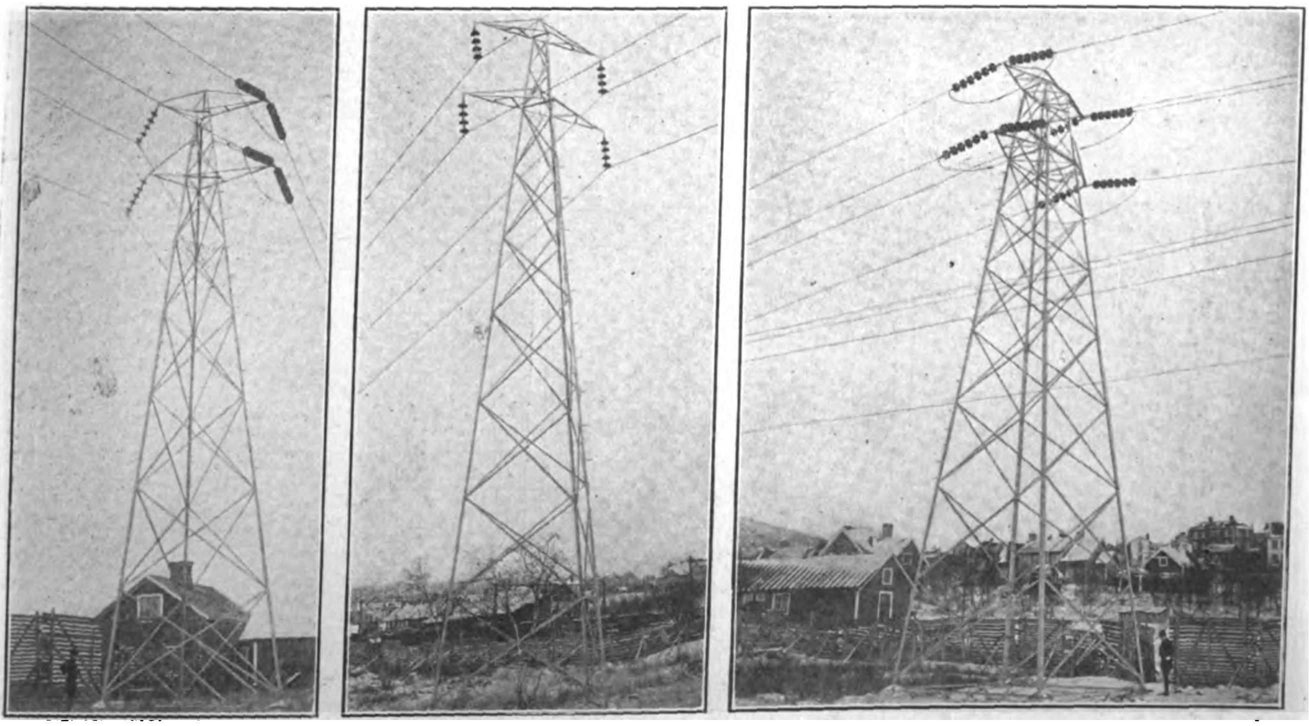
The entire electrification is through an absolutely uninhabited and uncultivated country. At Kiruna one may see a few stunted birches hardly more than 15 ft. high, but at Riksgränsen there is no vegetation at all. Kiruna has about 8000 people, most of them miners. The only inhabitants along the line are employees of the railway except the native Laplanders, whose possessions consist only of their tent equipments and reindeer. From the end of May to the beginning of July the sun does not sink below the horizon; on the other hand, it is invisible in December and January, during which period only a few hours of twilight occur.

Both the light and temperature conditions naturally offered some difficulties in building the transmission and contact lines, but the handicaps were minimized by careful preparation. The contract called for the completion of the work in two years, whereas the actual time available for work was only seven months. Most of the employees were secured from southern Sweden and were engaged about three or four months before the beginning of the work. The question of living quarters was settled by the use of about ninety old freight cars which were furnished by the Swedish State Railways. The men were divided into messes of ten each, every mess being supplied with one sleeper and one diner. Tents were also provided for shelters in sudden storms and for meals during working hours. The use of freight cars for living quarters proved a good expedient inasmuch as the men could move their homes as the work progressed. Food and clothing were supplied through a firm at Kiruna upon the delivery of paper tokens, which were cashed when the men were paid twice a month.

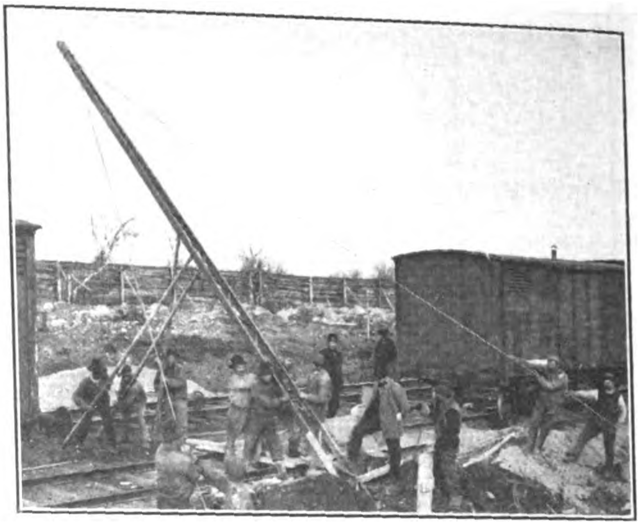
POWER STATION

It was intended originally to place the power station at a point 12.4 miles north of Kiruna, but this plant would have proved of insufficient capacity after the line had been extended to Lulea. It was therefore decided to build the station at Porjus Falls, 74.4 miles south of Kiruna. The ultimate capacity of these and the neighboring falls is placed at 250,000 kw, so that the location is ideal for further railway and industrial applications.

The first construction at Porjus Falls involved the erection of a dam to raise the level of Lake Porjus about 16 ft., thereby attaining a head of 180 ft. A number of subsidiary reservoirs take care of the great fluctuations which are to be expected in railway service. The machinery room is built in solid rock at a depth of 164 ft. The initial installation consists of three eight-pole single-phase generators for railway service, each with a maximum capacity of 10,000 kva, and one three-phase generator with a maximum capacity of 11,000 kva for supplying energy to the mining works at Gellivare and Kiruna. An emergency three-phase machine can also be coupled to one of the single-phase



POLAR ZONE RAILWAY—TRANSMISSION TOWER AT A CURVE. STANDARD 80,000-VOLT TRANSMISSION TOWER WITH SUSPENSION INSULATORS FOUR IN SERIES. ANCHORAGE TRANSMISSION TOWER WITH INSULATORS SIX IN SERIES ON EACH END generators. The railway machines generate 4000 volts at fifteen cycles and are driven by turbines which run at 225 r.p.m. The machines are completely inclosed but are furnished with forced ventilation. Although the turbo sets are started and stopped by hand, speed regulation is obtained by means of remote control from the switchboard. Both the transformers and switchboard are built above the machinery room to secure the benefit of daylight. The six individual transformers step up the voltage to 40,000, the transmission potential of 80,000 volts being obtained by connecting the low-tension side of each pair of transformers in parallel and the high-tension side in series. Each transformer has a continuous rating of 3000 kva, and is of the oil-cooled type. The high-tension middle point of the transformer group is grounded across resistance in order to carry off static charges and to reduce the demands upon the insulation. The transformers are also protected with horn type lightning arresters and choke coils. Only the high-tension side of the power station has oil switches and these are operated through remote control.

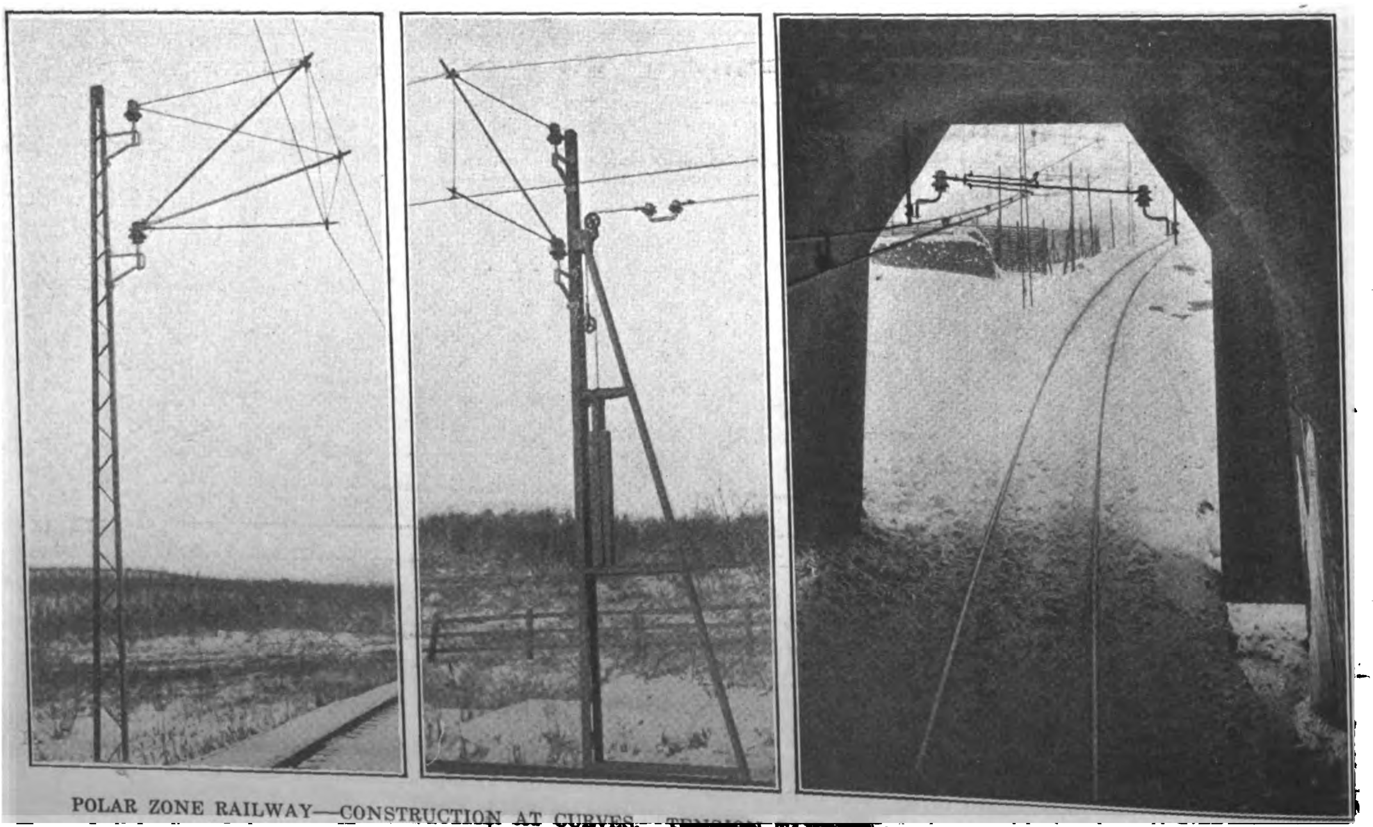


POLAR ZONE RAILWAY—ERECTING AN A-FRAME POLE FOR THE CONTACT LINE. SHOWING ALSO FREIGHT-CAR QUARTERS OF WORKERS

Transmission System

The power station, as previously noted, is 74.4 miles south of Kiruna. The electrification between Kiruna and Riksgränsen itself is 80.6 miles long and is supplied with four substations, namely; Kiruna, Torneträsk, Abisko and Vassijaure, located respectively 30.3 miles, 25.8 miles and 18.2 miles apart. The 80,000-volt lines are carried from suspension type insulators, which are hung from the opposite ends of structural steel cross-arms. On tangent and slight curves the insulators are placed in chains of four. At sharp curves, however, six pull-over insulators are the rule. The four cables between Porjus and Kiruna are of 80 sq. mm. (nearly No. 000) cross-section. Between Kiruna and Torneträsk the cross-section is 70 sq. mm. (a little more than No. 00) and between Abisko and Vassijaure 50 sq. mm. (slightly less than No. 0). All cables have seven wires. The transmission is carried on triangular steel towers 59 ft. to 62 ft. high which are generally located 640 ft. apart, but some spans are as long as 1050 ft. The towers are anchored in concrete foundations sunk 6 ft. to 8 ft. in the ground. Owing to the great length of the section between Kiruna and Porjus, three circuit-breaker houses were built and equipped to facilitate the discovery of defective insulators and to serve as lightning arrester houses.

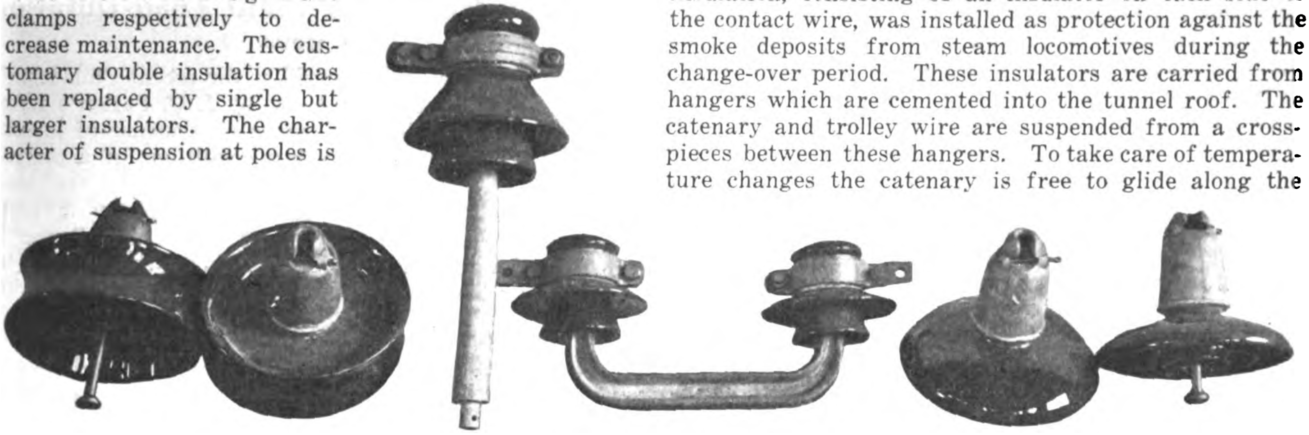
Each substation has three oil-insulated transformers, which have a continuous rating of 1000 kva each. These transformers are arranged to step down the voltage from 80,000 to 15,000. The highest permissible momentary loading per transformer is 2700 kva. In addition to the oil insulation, a ventilating shaft supplies cold air to each transformer. As at the power station, every transformer is placed in a separate compartment and rails are used to permit them to be rolled out for



POLAR ZONE RAILWAY—CONSTRUCTION AT CURVES. TENSION TAKE-UP DEVICE. STANDARD FORM OF TUNNEL CONSTRUCTION inspection and repair. The generating equipment was furnished by the "A. S. E. A." of Västeras, Sweden, while the other electrical equipment is of Siemens-Schuckert manufacture.

CONTACT LINE

The greater part of the contact line is of the single catenary type with A-frame poles spaced 172 ft., and hangers spaced 58 ft. The catenary is a seven-strand copper cable of 50 sq. mm. (approximately No. 0) section, while the trolley is of No. 8 profile of 80 mm. (approximately No. 000) section. Copper and bronze were used for the hangers and clamps respectively to decrease maintenance. The customary double insulation has been replaced by single but larger insulators. The character of suspension at poles is somewhat unusual. A separate gas-pipe bracket is employed for the catenary and contact line, that for the catenary being stiffened by a diagonal which is carried outward from the insulator of the trolley bracket. Both insulators are screwed by means of hemp into strap-iron struts within 9 in. from the poles. The bracket piping is attached to the insulators by means of lead-lined caps in such fashion that the brackets turn automatically to allow for dilatation in the suspension system. The customary tension take-up weights are installed at intervals of 0.8 mile. At these points, also, the railway has installed section breakers comprising a simple knife switch, horn arc blowout and a lever which can be operated from the ground. Sectionalization to so great an extent is unusual but will be helpful in discovering the location of defective insulators.



POLAR ZONE RAILWAY—DEAD-END TRANSMISSION INSULATORS AT LEFT, CONTACT LINE INSULATORS IN CENTER AND SUSPENSION TRANSMISSION INSULATORS AT RIGHT

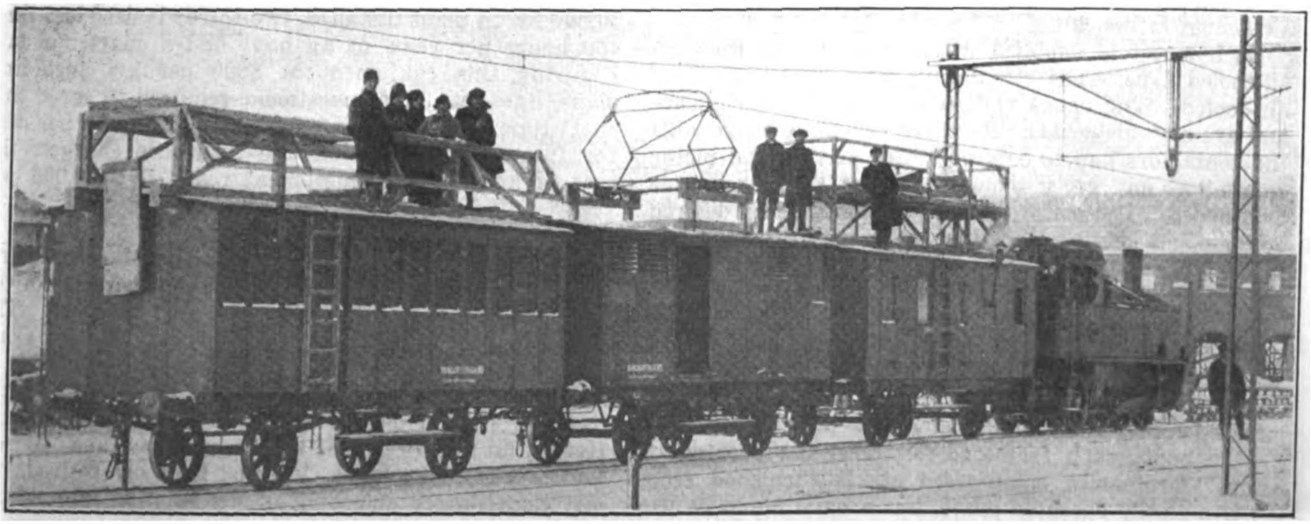
At yards and in other places where there are more than three tracks the contact system is carried from light catenary bridges. In this construction the bracket from which the catenary is suspended is also a piece of movable piping, and all insulation is afforded by double insulators in the catenary itself. Protection against static charges at stops where there are no sub-stations is afforded by lightning arresters and enamel resistances which are installed in wooden huts. These equipments may be cut out of circuit by the horn switches at the tension take-up points.

Special attention is directed to the construction devised for tunnels and snow galleries. In tunnels, double insulation, consisting of an insulator on each side of the contact wire, was installed as protection against the smoke deposits from steam locomotives during the change-over period. These insulators are carried from hangers which are cemented into the tunnel roof. The catenary and trolley wire are suspended from a cross-pieces between these hangers. To take care of temperature changes the catenary is free to glide along the cross-piece within loops. In the snow galleries the standard outside construction is used wherever clearance conditions are found to be satisfactory. On open sections the trolley wire is at least 18 ft. above the rails and in covered sections as low as 15 ft.

In constructing the overhead line, special trains were made up on which working platforms were built on the roofs of alternate cars to a length equal to a complete span. The catenary and contact wire were unreeled and erected simultaneously, the erection of the hangers following.

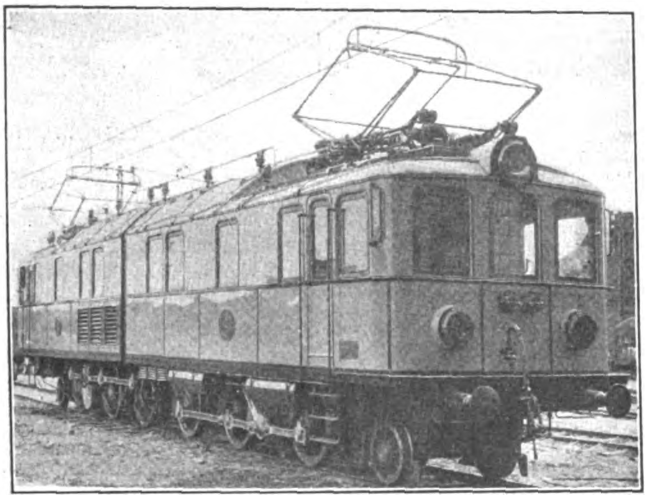
LOCOMOTIVES

Exclusive of the locomotives, the average weight of a passenger train is 200 metric tons and of an ore train, 1855 tons. It was specified that the passenger and ore trains must be hauled at 31 m.p.h. and 18.6 m.p.h. re-



POLAR ZONE RAILWAY—CONSTRUCTION TRAIN WITH PANTOGRAPH SET UP TO GAGE CONTACT WIRE CLEARANCES—SHOWING ALSO BRACKET SUSPENSION OF CATENARY AT BRIDGES spectively over grades of 1 per cent and curves of 1640 ft. radius. The equipment secured from the Siemens-Schuckert Company comprises two passenger locomotives of Type 2-B-2 (two pony axles, two drivers and two pony axles on one truck) and thirteen ore locomotives of Type 1-C + C-1 (one pony axle and three drivers per each of two trucks). Each half of the ore locomotives has a floor-mounted motor with jackshaft connection to the driving rods. The oil reservoir for the jackshaft is fitted with a small heating resistance to prevent the freezing of lubricant during low temperatures. Wood faced with sheet iron is used for the locomotive housing on account of climatic conditions, but side louvers are provided for ventilating the apparatus. The roof may be taken off to exchange parts of the machinery. Each housing of the twin locomotive is partitioned into a motor and compressor room, high-tension room and control cab. For operation of loaded trains the New York automatic air brake is used, while straight air is employed for empties.

The motors are of the series type with auxiliary excitation. No resistance leads are used between the armature coils and the commutator. The speed of the motors is regulated by changing the secondary voltages at the main transformer. The reverser is built on the motor frame in order to secure the shortest possible course for the heavy current circuits between this device and the motor brushes. The reverser is operated by means of a compressed air cylinder which is controlled from a solenoid in the cab.



POLAR ZONE RAILWAY—STANDARD FREIGHT LOCOMOTIVE FOR KIRUNA-RIKSGRAENSEN RAILWAY

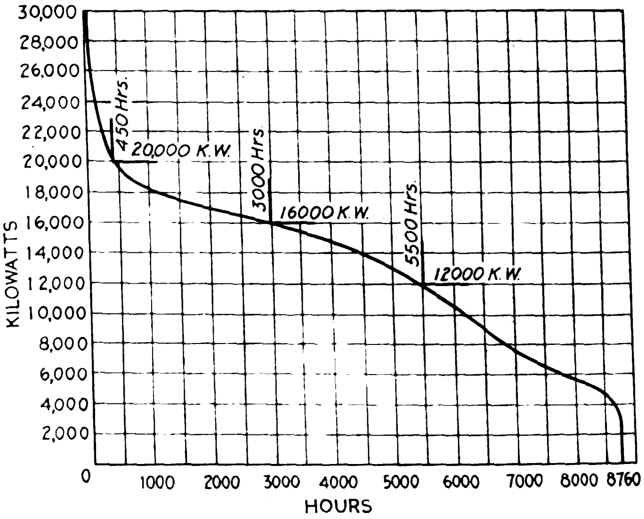
Each motor is supplied with a core transformer of oil-cooled type. The circulating piping for the oil is air-cooled. The choke coils are provided in triplicate and are also air-cooled. As there are three choke coils the contactors handle only one-third of the total motor current at any given moment so that they are never overloaded. The motorman may operate at any desired voltage and speed within his range without returning the controller to the zero position. The controller has the usual deadman's handle and emergency braking feature. The high-tension oil switch may be opened and closed mechanically or from push buttons in the cab. The current collectors are of the ordinary Siemens pantograph type with auxiliary bow, but the compressed air cylinder and springs are placed very close to the pantograph frame to minimize the packing of snow. Ordinarily, compressed air is furnished from an electrically operated pump, but a hand pump is also available for contingencies. The locomotives are illuminated by means of 23-volt metallic filament lamps, which are connected to a storage battery when line current fails. Two 2-kw electric heaters are placed in each cab, and heaters are also provided for drying sand.

OPERATION

If trains could be operated every day the proposed schedules would take care of 4,130,000 tons to 6,200,000 tons of ore a year. In view of snowstorms, irregular outputs, holidays, etc., the actual amounts which will probably be transported under these schedules are 3,200,000 tons and 4,850,000 tons. The regular operation of ore trains is to begin at the end of the current year.

The Electric Power Plant Load-Duration Curve

Much interest was aroused at the recent Philadelphia convention of the N. E. L. A. by J. C. Parker's reference to the load-duration curve as a means of investigating the efficient operating conditions of a central-station system. Reproduced herewith is the load-duration curve for the Rochester Railway & Light Company, Rochester, N. Y., of which Mr. Parker is electrical engineer. The curve shows the relation between the load carried and the number of hours in the year for which the load endures. For example, only about 4000 kw of load continues every hour in the year. The equipment necessary to carry 12,000 kw is used 5500 hours per year. But, on the other hand, of the 30,000 kw in plant installed, two-thirds is used less than 450 hours per year, or an hour and a quarter a day. Figuring this equipment at $500 per kw, including plant, lines, etc., the investment required to serve this short-time demand is $5,000,000. Allowing 15 per cent for interest, depreciation and insurance charges, the cost of keeping this equipment ready is $750,000 per year.



LOAD-DURATION CURVE OF ROCHESTER COMPANY.

The Bridgeport *Farmer* in its issue of Aug. 25 reviewed the incidents connected with the operation of the first trolley car in that city on Aug. 24, 1894. The company was known as the Bridgeport Traction Company, and the property is now included in the system of the Connecticut Company. Two of the officers of the company still reside in Bridgeport. They are Col. N. H. Heft, who was president of the company, and Andrew Radel, general manager. Colonel Heft has retired, but Mr. Radel, after disposing of his traction interests in Bridgeport and other cities, entered the oyster industry and is said to be the largest operator in that field in the world.

Railway Electrolysis and Methods of Treatment

The Author Describes Methods of Making Electrical Measurements to Determine Electrolytic Conditions and Discusses the Several Methods in Use for Preventing Electrolytic Corrosion

BY I. W. GROSS, NEW YORK

The subject of railway electrolysis has been understood in a general way for some time, but it is only recently that its relation to electric traction problems has been extensively analyzed and that remedial measures have been adopted. This change has been brought about in part by the increase in density of traffic over railway lines, in part by the increase in the number of gas, water and cable lines paralleling the tracks, thus increasing the conductance of the leakage current path, and in part by the widespread application of electric power to traction purposes.

The result of these natural growths of traffic and population has been to bring the electrolysis problem to the point where the deteriorating effects of stray currents can no longer be passed off as atmospheric corrosion, where damage is caused to gas or water pipes, or as plain chemical action where cable sheaths are injured. On the other hand, not all failures of gas pipes or cable sheaths are due to electrolysis, even where railway tracks parallel or cross them. It is only by thorough testing and careful analysis that trustworthy results can be obtained and definite conclusions drawn.

It is the purpose of this article to describe the most generally used methods of testing for electrolytic troubles, to present actual test data, and to discuss several of the methods employed in mitigating electrolysis trouble, pointing out their merits and defects.

In dealing with electrolytic problems three questions are involved. In the first place, does any electrolysis exist? Second, what is its source? That is, does the stray current come from the railway tracks or from some other conductor, and if from the former from what part of it? Finally, what is the most effective and economical method of removing or alleviating the trouble?

MANIFESTATIONS OF ELECTROLYTIC CORROSION

Where electrolytic action on a lead cable sheath is severe there are formed dark red or white deposits upon it. It seems probable that the red deposit, an oxide of lead, is formed electrolytically first, and that later this oxide is chemically changed to an insoluble lead salt when acidified water leaches through the duct line and runs along the bottom in contact with the oxidized lead. Sometimes the deposit is white from the very start, the red oxide of lead not being apparent. Whatever the deposit on the sheath, be it either red or white, continued electrolytic action ultimately pits the cable until the sheath is eaten through in spots, and failure takes place when air and water gain access. The spots where the cable is pitted are on the side in contact with the duct, and are usually from 1/8 in. to 1/4 in. in diameter. Sometimes, where the action has been violent, these pits or spots are sufficiently close together to give the sheath the appearance of a grater. For several feet the lead may be more than half eaten through and yet the cable may remain intact.

Since electrolytic action takes place only between a metal and an electrolyte, and since, even in wet manholes, the cables are often clear of water, most of the electrolytic action takes place wholly within the duct line where the trouble cannot be detected until the cable is removed. Such is the usual case, and means other than mere inspection must be adopted.

With cast-iron pipe, electrolytic action manifests itself in a layer of non-magnetic material over the outside of the pipe, identical in external appearance with the pipe itself, but far lighter and absolutely devoid of mechanical strength. Unlike lead, cast iron does not pit but is deposited in a uniform layer about the pipe where the current leaves it for water or some other electrolyte. In the case of a certain 14-in. cast-iron pipe, 3/4 in. thick, submerged in salt water, the writer found a half-inch non-metallic coating on the outside, formed by electrolytic action. When the pipe was removed from the water it was uniform in size and symmetrical in shape, but it took only a few blows from a light hammer to separate the half-inch coating from the thin metallic shell which remained of the original pipe. Here again, while the pipe was in service inspection alone would not have detected the trouble; and some other means must be adopted in such cases to detect trouble before the damage has assumed serious proportions. This at once leads to electrical tests to determine the presence of current in these conductors.

TESTS FOR CURRENT IN PIPES

The current survey, as it is generally known, is the first test to apply to a conductor where electrolytic action is being sought for. This merely consists in spanning a short section of the conductor, say, a gas pipe, with a low-reading voltmeter and observing the deflection. A millivoltmeter is generally used, since the drop along the pipe is always small. From the size of the pipe its resistance per foot can readily be obtained from tables, and the current flowing in the conductor can be computed by the application of Ohm's law.

In using a low-reading millivoltmeter as above described, there are several precautions which should be observed. In the first place, the meter should have its zero in the center of the scale rather than at the end, as in most commercial test meters. This is advantageous, as the current on a pipe often reverses, and it is impossible to reverse the connecting leads quickly enough to permit the observation of the negative reading.

Second, great care should be taken to thoroughly clean all contacts before starting the test, as the meter itself is of very low resistance (even when specially constructed for this kind of work). Where contact is made to a gas pipe, the pipe surface can be cleaned best with a sharp file to remove paint and rust.

As a third precaution, the millivoltmeter should never be used to take measurements across joints in pipes or from one pipe to another, before these tests have been made with a high-range voltmeter. This precaution is necessary to avoid burning out the millivoltmeter. Joints in supposedly electrically continuous conductors have been observed by the writer, across which there were drops of from 1 volt to 17 volts. The normal voltage drop across such joints when in good condition would under the most adverse circumstances not be over 0.01 volt, i.e., 10 millivolts.

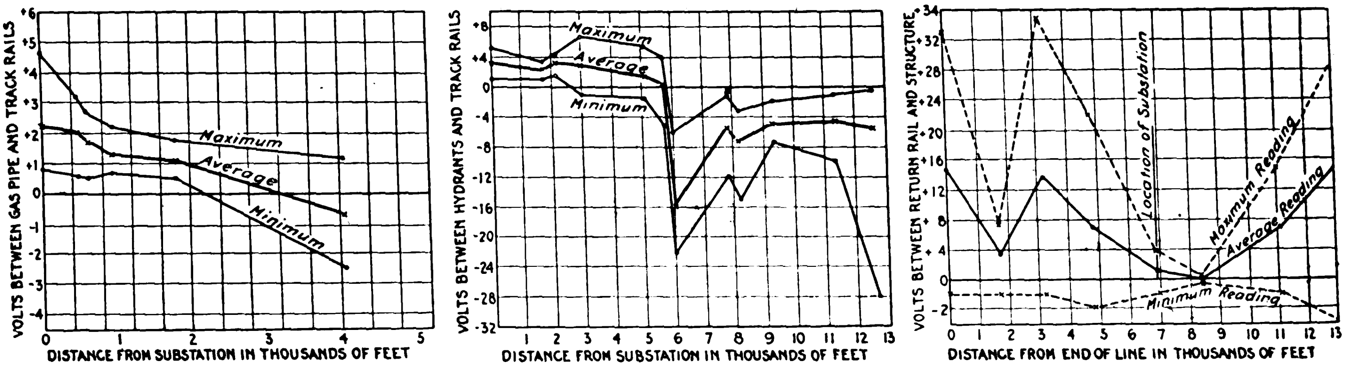
When current has been detected in a pipe the survey should be continued at various points along the line. Measurements made at distances of 500 ft. are usually frequent enough to show consistent results, and often the distance between data points can be increased to 1000 ft. or more.

If the source of current is a railway line, the cur-

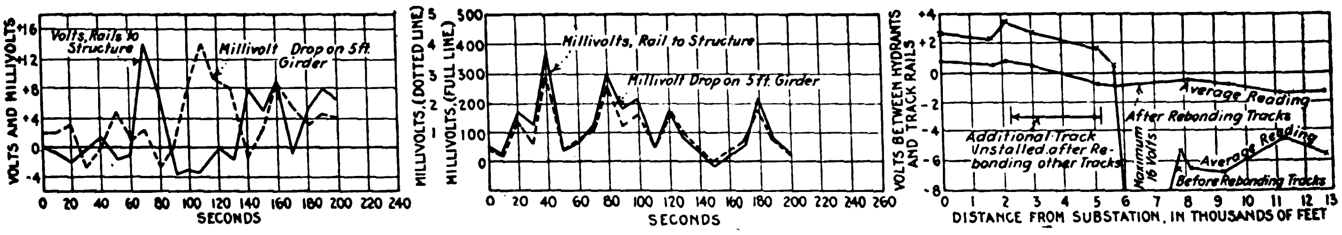
[NOTE: Mr. Gross is an associate member A. I. E. E. and engineer motive power department Interborough Rapid Transit Company.—EDS.]

rent will fluctuate over a considerable range, and in most locations it will reverse in direction from time to time. To obtain any comparable results, therefore, it is best to take forty or more readings at ten-second intervals and to average them algebraically to find the effective value of current in the pipe at the test point. As few as twenty readings will give results which can be checked consistently if the traffic on the line is heavy, while if it is very light, as on suburban trolley lines, a period of observation extending over five or ten minutes may be necessary.

In general the period of test should extend over one complete cycle of car movement; that is, from the time one car passes over the test point until the subsequent car reaches that point. The average readings obtained in this way are now plotted as ordinates against the distances from the station as abscissas, and in this way a graphical plot showing the relative magnitudes of currents in the pipe is obtained. After gaining some facility with this method of testing it is often unnecessary to make the actual plot, as the average readings show the conditions.



RAILWAY ELECTROLYSIS—FIG. 1—POTENTIAL SURVEY OF RAILWAY TRACK RETURN, GAS PIPE TO RAILS. FIG. 2—POTENTIAL SURVEY, HYDRANTS TO RAILS, SHOWING EFFECT OF DEFECTIVE BONDING. FIG. 3—POTENTIAL SURVEY, RETURN RAILS TO STRUCTURE



RAILWAY ELECTROLYSIS—FIG. 4—POTENTIAL AND CURRENT FLUCTUATIONS, STRUCTURE NOT BONDED TO RAILS FIG. 5—POTENTIAL AND CURRENT FLUCTUATIONS, STRUCTURE BONDED TO RAILS. FIG. 6—POTENTIAL SURVEYS, SHOWING EFFECT OF REBONDING TRACKS

The object of this current survey is not only to show the magnitude of current in the pipe but, from the average readings, to obtain some conception of where the current is entering and leaving the pipe.

POTENTIAL SURVEYS

The potential survey is identical with the current survey, except that readings are taken between the pipe under study and trolley rails, water mains and other paralleling conductors. A voltmeter is used for this test and no special precautions are necessary, as the meter has a high resistance. The voltmeter should have a center-zero scale, as potential readings, like current readings, are constantly reversing in most localities. The potential survey gives data for a chart showing the potential of the pipe referred to track rails, hydrants, etc. The purpose of this chart is to show the points along the line where it is possible for current to flow from one conductor to another. The results of several such potential surveys taken on different railway lines are shown graphically in Figs. 1, 2 and 3. The significance of these curves will be discussed later.

TESTS OF SOURCES OF LEAKAGE CURRENT

In some cases where electrolytic trouble is suspected there may be two or three foreign companies from whom it is possible for stray current to come. For example, a water main may be running along parallel to the car tracks of two different railway companies. There is current in the water pipe, let us say, and the tracks of both lines average positive in potential with respect to the water pipe. The problem is to determine which company is responsible for the stray current on the pipe. A method of fixing the blame which has met with considerable success is what may be termed the "volt-ampere" test. It consists in measuring simultaneously the potential difference between the water pipe and the rails of one company, and the current flow in the pipe. Readings of both meters taken together at ten-second intervals for about three minutes will usually give the desired information. The results of two such tests are shown in Figs. 4 and 5.

The object of a test such as the above is to associate the change in potential difference between the water pipe and rails with the values of current in the pipe. For example, if the current increases with increase of potential difference between pipe and rail evidently part of the stray current is coming from the rail, as is the case in the example shown in Fig. 5. If there is no corresponding change in current, as indicated by the millivoltmeter, very little if any current is coming from the rail. Fig. 4 shows such a case.

Another test sometimes applied with good results is the "ground" test, or, as it might properly be called, the "short-circuit" test. It consists of temporarily joining the return rail and the gas pipe by a good conductor with an ammeter in series, to determine the amount of "current flowing from rail to ground" or vice versa. Such a test is apt to lead to erroneous conclusions unless the results are carefully interpreted.

Suppose, for example, that a connection made as above indicated carries 250 amp. It cannot be inferred that 250 amp is the current flowing from the rail under normal conditions. A current as great as 250 amp under these test conditions indicates merely that the conductivity of the leakage path of the current from the gas pipe to the negative bus of the substation is high, although under normal conditions there may be very little, if any, current flowing from track rails to gas pipe. In other words, this test does not in any way indicate the normal current flow from or to the rails. On the other hand, suppose the current flow through the bond is but 15 amp. Then it is evident that the conductance from gas pipe to negative bus is very low and, even if artificial electric contact were made at this point between rail and pipe, the leakage current from this pipe at some other point would be comparatively small.

SUMMARY OF TESTS

The tests which are generally most effective and instructive in analyzing electrolytic action as described above may be made advantageously in one tour of the ground. From the current survey is obtained the magnitude of current flowing on the conductor under test, and in general the points at which it enters or leaves the conductor. From the potential survey are obtained the possible sources and the distribution of the stray current. From the volt-ampere test can be determined the actual sources of the current.

When the magnitude, location and source of the stray current have been determined by the above methods, the query which presents itself is, "What is the most effective and economical method of removing or alleviating the trouble?"

ELECTROLYSIS MITIGATION

There are at the present time four well-recognized methods of protecting conductors against serious danger from stray current. They are: The bonding of the conductor to points of low potential on the rail return; the breaking up of the conductor into electrically short sections by the use of insulated joints; the limitation of the drop in the track rails, either by means of parallel conductors or insulated feeders, and the insulation of both positive and negative sides of the system.

BONDING TO STATION NEGATIVE BUSBARS

The first of the above-mentioned methods has been widely used, especially by telephone companies whose underground cable sheaths normally carry no current of their own. By bonding the sheaths of the cables to the negative bus in the substation, it is possible in most cases to maintain the potential of the sheaths negative to the earth throughout their entire length. Thus the current leaking into the sheath is conducted through a metallic bond to the substation from which it came and corrosion of the lead is eliminated. The same scheme of bonding has been applied to water and gas pipes, but on account of possible high resistance in joints in the pipes this scheme is not entirely satisfactory, even for the protection of the pipes themselves. Where the joint resistance is high, current will shunt around the joint through the ground, or the water, in the case of water pipe, and injury may result where least expected.

The magnitude of the stray current in conductors is increased enormously by bonding to a substation bus. Cases have been observed where the increase in cable sheath current has been from thirty to 180 times the value of current with the unbonded condition. The result of this increase is that the larger current, being drawn from the rails produces electrolysis of the rails themselves, thus transferring the trouble from the cable sheaths or pipes to the property of the railway company. Further, the bonding of cable sheaths alone to the negative bus results in increased danger to gas and water pipes which are not bonded to anything, and at points along the line where gas and water pipes are negative to the rail damage may still result due to the cable sheaths being lower in potential than the pipes. Thus the section of the gas pipes which is in danger has been increased from an area near the substation to one covering the entire length of the line.

The use of the bonding system has resulted in increased stray currents and increased damage to railway tracks and, in general, to gas and water pipes. It seems undoubtedly true that this scheme of protection, which has been used quite extensively up to the present time, is the most to be feared of all remedies for electrolysis. Only by careful and painstaking tests and conclusions can the bonding system be applied with any degree of success, and even then its combined net effect is doubtful.

USE OF INSULATING JOINTS

The second method, that of breaking up the electrical continuity of the conductor carrying stray current, is very good in theory but its application is limited due to the labor of making and maintaining the insulated joints. Such joints in high-tension cables have, however, been in service for over two years to the writer's knowledge and have never given any trouble, although installed in a damp place. Similarly insulated joints in water pipes have effectively eliminated stray currents and, with a drop of 5 volts across the joint, have failed to show any signs of electrolysis. Some of these joints, also, have been in place for two years. The scheme of insulating the conductor, therefore, has been effective where tried, but it is costly and the joints are difficult to install and maintain.

INSULATED RETURN-FEEDER SYSTEM

The third method, that of using insulated return feeders, which has recently been discussed in the columns of the ELECTRIC RAILWAY JOURNAL, is meeting with considerable favor. It is interesting to note that this system was installed in the New York subway when first built about ten years ago, and it has been in successful operation ever since. The success of the system in New York is due to a large extent to the good insulation between track rail and ground furnished by the ties and rock ballast, as well as to the insulated feeder system.

The return-feeder scheme has been so thoroughly discussed of late that the method itself need not be repeated at length. In brief, it consists of limiting the drop in the track to a predetermined value, a value of 7 volts having been recently advocated, and allowing the larger part of the return drop to occur in the insulated feeders. This plan is reported to have reduced stray currents, but it should be borne in mind that its adoption does not eliminate electrolytic trouble but merely lessens it. By the proper placing of return feeders, the location of the dangerous sections can be altered as desired, but not the total area when the permissible voltage drop has been fixed. It is often possible, in this way, to remove a danger section to points remote from gas, water or cable lines. Thus, while the return-feeder scheme does not remove the trouble absolutely from the pipes it may very much lessen it.

COMPLETE INSULATION OF CONDUCTORS

The fourth method of electrolysis mitigation, that of insulating both positive and negative sides of the railway system, is the only method of giving perfect protection with railways using direct current. Such systems are now in use in Washington, D. C., and in the system of the New York Railways Company in New

York City. The New York company employs a telltale device, located in the substation, to indicate a ground on the system, thus permitting the maintenance of excellent insulation from ground for both positive and negative feeders. When applied to systems using overhead wires this method necessitates two overhead trolley wires and in such cases the conductance of the track rails is absolutely lost and an additional conductor must be supplied to carry the return current.

This insulating scheme has also been applied to elevated roads with absolute success. Here, however, only the conductance of the structure itself is lost, the track rails still being used for the return circuit, and additional copper is added where necessary to keep the drop within economic limits.

DISCUSSION OF TEST DATA

The potential survey represented in Fig. 1 was taken along the line of a trolley road using a ground return. The conditions for only part of the line are shown as, in this test, it was merely desired to determine the location of the neutral point, that is, the point where the rails became positive to the gas pipes. This potential plot is typical of grounded tracks, and the maximum average value of 2.6 volts between gas pipes and tracks at the substation is not excessive.

Fig. 2 represents the potential conditions of the tracks of the same trolley line, fed by the same substation as in Fig. 1 but along a different route. This is an end section, that is, it is fed entirely from one end. The erratic potential of the rails at about the middle of the line is due to broken bonds, as was determined by finding a maximum drop of 17.5 volts across two adjacent rail ends. This diagram represents abnormal track conditions, directly traceable, in this case, to a poorly bonded return.

Fig. 6 represents potential conditions before and after rebonding the above track. It will be observed that in this case an over-all potential reading, as referred to in recent issues of the ELECTRIC RAILWAY JOURNAL, would not show any abnormal conditions on the line. The over-all drop is approximately 8.1 volts, assuming no drop in the water pipes, while the maximum average potential difference between any two points of the line is 18.7 volts; or over twice that indicated by the over-all measurement. Thus it appears the over-all measurement is not final in determining track conditions.

It might be of interest to note in connection with the potential distribution shown in Fig. 2 that the potential gradient from the middle to the end of the line is away from the substation. This would lead one to believe that the return current was entering the ground in the vicinity of the end of the line. The correctness of this theory was proved by the condition of the track rails at the end of the line when removed. These rails, which gave no sign of excessive wear due to traffic, were found with the lower flanges almost entirely eaten away, and in some cases more than half the vertical web was gone.

Referring again to the 7-volt total permissible voltage drop regulation, it is interesting to note that the approximate value of 8.1 volts is about 17 per cent in excess of the recognized safe value. Yet here is a case where nearly half the line current must leave the rails before reaching the substation. In other words, the 7-volt drop regulation alone is not a sufficient safeguard without further stipulations as to the condition of the track return.

The data shown in Fig. 3 were taken along the line of an electric road where the tracks were not in normal contact with the ground. The point 1.7 miles from the end of the line, where a comparatively low potential is observed, is at the termination of negative insulated feeders. The distribution of potential is, therefore, due to the negative feeder system rather than to any abnormal track conditions.

At the end of the line the average potential of the rail is 15 volts above the track structure, or roughly above earth. This is more than twice the 7-volt standard. This relatively high potential was misinterpreted by the owners of a building situated at this point, who thought that they detected evidence of stray current in the steel work of their building. The high potential was believed by them to indicate a large current flow in their building. To settle this point the volt-ampere measurements shown in Figs. 4 and 5 were taken. These show conclusively that no leakage current from the rails to the structure existed under normal conditions, but that an accidental bond between rail and building would be most detrimental. High-potential readings from conductor to rails show, then, nothing whatever in regard to conditions of current flow in the conductor.

GENERAL SUMMARY

It has been the endeavor in this article to bring out the following points:

1. It is usually possible to tell from the appearance of lead and iron whether they are being acted upon by stray currents, wherever they can be freely inspected.

2. Electrical tests are the only sure means of determining existing electrolytic conditions. Of these tests the current survey is the only one that gives a real criterion, the potential survey merely showing locations where electrolysis is likely to occur. High-potential differences, with no current flow on the conductor under suspicion are not injurious. The volt-ampere test may be effectively used to trace out the source of stray current.

3. Of the remedial measures adopted in connection with electrolytic troubles up to the present time, the methods of cure in order of effectiveness are as follows. *a.* Insulated positive and negative rails. This system is, in general, very expensive. *b.* Insulated joints in all water, gas and cable lines, with due consideration for the condition of the return bonding system. On account of the high cost of installing insulated joints this scheme is impracticable, especially where there is any considerable number of foreign conductors paralleling the railway line. Further, the durability of such joints is open to question; and experience has not been sufficient to assure immunity from electrolysis when there is a considerable drop across the joints. *c.* Insulated feeder systems with regulated drop in the track circuit. *d.* Solid bonding of endangered conductors to the negative bus of the substation, or to other points of low potential on the line. This is the most dangerous method of protection and should be avoided wherever possible.

4. It is firmly believed that the specified limitation of the average rush-hour drop between any two points in the track to 7 volts is not applicable in all cases. It is believed that in some cases this drop can be exceeded with safety, while in other cases it should be reduced below 7 volts.

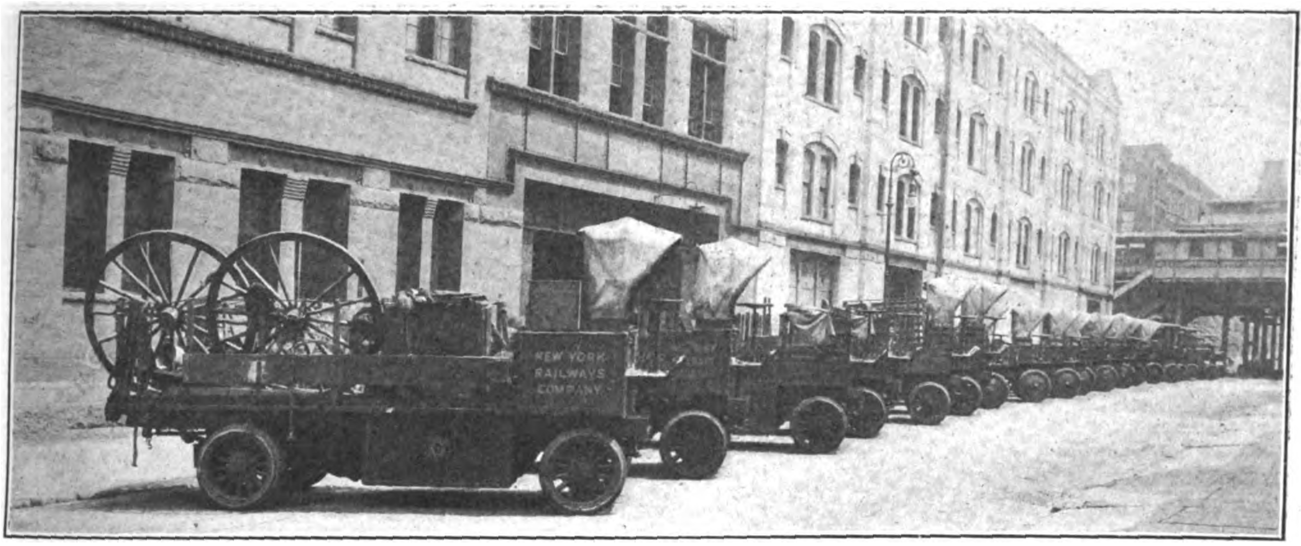
5. Since it is evident that the condition of the track bonds materially affects electrolytic conditions, it is suggested that the voltage drop across the rail joints be specified in terms of feet of rail, in addition to the specifying of the allowable voltage drop in the tracks. Satisfactory track bonding can be maintained only by periodic tests.

6. The over-all voltage check on a line is not sufficient evidence of adherence to the stipulated allowable drop, as shown in Fig. 2. However, this over-all voltage check would be adequate if the bonding were all in good condition and good bonding can be obtained with the aid of periodical tests.

Electric Motor Trucks for New York Railways

Particulars Are Presented of the Twenty-nine Electric Vehicles Which Are Used by This Company as Service Trucks of Different Types

The New York Railways Company placed in operation during the latter part of 1913 the largest equipment of self-propelled trucks ever ordered by an electric railway to replace horse-drawn trucks and wagons of various kinds. In order to fix the number of each kind of vehicle required, a diagrammatic study was made of the horse-drawn vehicles then in use to determine the moving and standing time of each truck and of the number of trucks employed continuously throughout the year. The time data were obtained from the reports of arrival and departure at stopping points as turned in by the drivers, while mileage was calculated from a map. A detailed comparison was also made of gasoline versus electric vehicles, and this showed that for the short runs in congested districts, comprising most of the service, electric vehicles were to be preferred because of their greater simplicity of operation and their economy on the bases of total first cost, operation, fixed charges and depreciation. All of the motor trucks were ordered from the General Vehicle Company, Inc., Long Island City, N. Y.



NEW YORK RAILWAYS MOTOR TRUCKS—ASSEMBLY OF TRUCKS WITH 10,000-LB. CABLE WAGON IN FOREGROUND

Specifications were prepared by J. S. Doyle, superintendent of car equipment, for twenty-nine vehicles of different capacities as follows:

- One 1000-lb. open express type wagon,
- Two 3000-lb. panel type delivery wagons,
- One 2000-lb. panel type bank wagon,
- Five 4000-lb. emergency wagons,
- Fourteen 7000-lb. steel dump trucks,
- Four 7000-lb. platform and stake trucks,
- One 10,000-lb. platform, stake and reach truck,
- One 10,000-lb. platform, stake and windlass truck.

At present these vehicles are charged at night from one central charging station, although the use of more stations for day boosting charges is contemplated.

1000-LB. AND 2000-LB. TRUCKS AND BANK WAGON

The 1000-lb. open and 2000-lb. closed delivery trucks carry transfers, stationery, light track material, pipe and lumber for small jobs, etc.

The bank wagon was built for collecting money at different receiving points in the carhouses and carrying it to the company's banks. The bank wagon route covers from 25 to 30 miles a day. On account of its purpose, the body has been designed with the following special features:

An inside sliding steel door, 22 in. x 30 in., is installed 8 in. in the back of the driver's seat, on the right-hand side, to serve as a passage for money bags only. This door has been made sufficiently large to allow a man to lean out and place a money bag, which weighs from 50 lb. to 75 lb., on the shoulder of a man standing on the sidewalk. It may be observed that by this arrangement the man to whom the money is handed is always facing the sidewalk, and, therefore, he is not likely to be taken by surprise. A barred window, 12 in. x 12 in., is built in at the rear end of the body for ventilation.

Two heavy wire screen doors, swinging inwardly against the sliding steel side door, at the back of the driver's seat prevent access to the interior of the body when money is being handled at the side door described. Doors which swing inwardly are used because the inside guard is compelled to close them before he can get at the side door to open it. Thus only one kind of door can be open at a time. There are doors on each side of the footboard, as is ordinarily the practice now with pleasure automobiles, that is to say, the four-door arrangement is used. This makes it difficult for a highwayman to obtain a foothold. Steel plates are placed inside the body to protect the men from gun fire.

EMERGENCY TRUCK

The emergency truck is used for accidents, and as a hook is attached to each end it can be maneuvered more easily than a horse-drawn wagon when it has to pull wagons or other obstructions off the track. It weighs 7600 lb. complete and has a maximum drawbar pull of 4500 lb. While an average trip is about 3 miles and an average daily performance is 15 miles, the battery on one charge is capable of propelling the regular load of 4000 lb. for at least 30 miles. This truck also carries a complete tool kit.

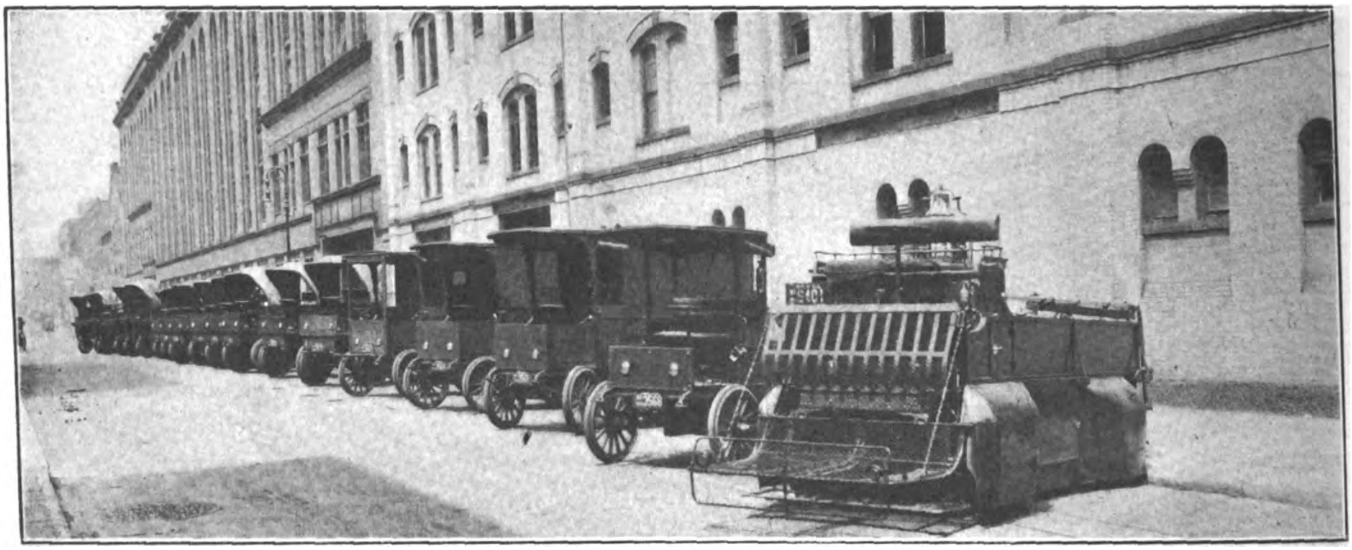
Owing to the fact that accidents are apt to occur through pedestrians being side-swiped when this wagon is turning corners at high speed, it was decided to completely inclose the running gear. The illustration shows that the front of this wagon is protected by the company's own type of combination wheel guard and fender. If this apparatus strikes a standing person, the upper part of the gate or apron of the guard throws the victim into the fender, while the lower part of the apron forms a continuation of the fender to take care of the overhanging limbs of the person struck. Furthermore, at the time of impact the wheel guard section is tripped in the ordinary way, so that even if the person struck should fall out of the fender, it would still be impossible for him to be dragged under the car. If this apparatus should strike someone who is lying prone on the track the wheel guard action alone is sufficient to prevent him from being caught under the trucks. The fender on striking a person, who is either standing or lying prone, automatically stops the truck by shutting off the power and applying the brakes.

7000-LB. TRUCKS

TABLE III, SHOWING GENERAL DIMENSIONS (LOADING SPACE) OF VEHICLES

	Length	Height	Width	Gage	Wheelbase
1,000-lb. open express	8 ft.	....	3 ft. 6 in.	56 in.	86¾ in.
2,000-lb. panel delivery	8 ft.	5 ft. 6 in.	4 ft.	60 in.	103 in.
2,000-lb. panel bank	8 ft.	5 ft. 6 in.	4 ft.	60 in.	103 in.
4,000-lb. open emergency ...	10 ft.	....	4 ft. 8 in.	61 in.	111½ in.
7,000-lb. dump* .	....	60 cu. ft.	....	69 in.	100 in.
7,000-lb. platform and stake** ..	15 ft.	....	4 ft. 6½ in.	65 in.	128¼ in.
10,000-lb. platform and reach*** .	15 ft. 6 in.	....	5 ft.	68¼ in.	139 in.
10,000-lb. platform and windlass .	15 ft. 6 in.	....	5 ft.	69 in.	139 in.

* Height 5 ft. from ground to the top of dump body, full load.
** Side stakes 3 ft. 6 in. Rear stakes 5 ft.
*** Side stakes 3 ft. 6 in. Rear stakes 5 ft. 6 in.



NEW YORK RAILWAYS MOTOR TRUCKS—ASSEMBLY OF TRUCKS WITH EMERGENCY WAGON IN FOREGROUND

TABLE I, SHOWING MAXIMUM SPEED AND MILEAGE OF DIFFERENT VEHICLES

Vehicle	Maximum Speed	Maximum Mileage
1,000-lb. open express	12	45
2,000-lb. panel delivery	10	50
2,000-lb. panel bank	15	50
4,000-lb. open emergency	15	30
7,000-lb. dump	5	40
7,000-lb. platform and stake	8	40
10,000-lb. platform reach	5	30
10,000-lb. platform windlass	5	30

The 7000-lb. dumping trucks for sand, manhole refuse, etc., are of steel watertight construction. The dumping is effected through the rear end of the body by a manually-operated arrangement located just in front of the dump body. Two round iron-bound oak blocks, about 10 in. in diameter, are placed on each side of the rear end of the dump body to take the shock when the body, in dumping, strikes the pavement or the guard timbers on the dumping platform. This protects the body from the damage which would otherwise occur during the dumping operation. The platform stake trucks are used for hauling from the yards miscellaneous material like cement, tie rods, lumber, piping and also paving material when the dump wagons are not available. These wagons are furnished with removable side planking up to the height of the tailboard, so that small, loose material can be readily carried.

10,000-LB. TRUCKS

The 10,000-lb. stake-and-reach truck is intended chiefly for rails and structural material. The 10,000-lb. platform windlass truck is used principally for handling reels, pulling cables, etc. The windlass is operated by a GE-1020 motor, driving a "niggerhead" through spur gearing. It may be run backward or forward by means of two controllers, one of which is used on battery voltage and the other on railway voltage. In the latter case connection is made to the channel rail through a manhole. With this apparatus the cable is pulled at the rate of about 60 ft. per minute, compared with the hand-winch speed of 30 ft. per minute.

GENERAL FEATURES

Although a wide variety of service is called for in this order, certain parts and requirements are common to all of the equipments or differ only in dimensions,

TABLE II, SHOWING TYPES OF DRIVE, BATTERY AND CONTROL FOR THE STORAGE BATTERY MOTOR TRUCKS OF THE NEW YORK RAILWAYS

Vehicle	Drive	Battery	Controller
1,000-lb. open express	1—No. 1020, 3 hp, 85 volts, 20 amp., 2000 r.p.m.	44 WT cells, 11 plates	S-35 continuous torque, 4 speeds ahead, 2 reverse
2,000-lb. panel delivery	1—No. 1026, 3 hp, 85 volts, 28 amp., 1200 r.p.m.	44 WTX cells, 17 plates	S-35 continuous torque, 4 speeds ahead, 2 reverse
2,000-lb. panel bank	1—No. 1026, 3 hp, 85 volts, 40 amp., 1600 r.p.m.	44 WTX cells, 17 plates	S-35 continuous torque, 4 speeds ahead, 2 reverse
4,000-lb. open emergency	1—No. 1022, 4 hp, 85 volts, 60 amp., 1600 r.p.m.	44 WTX cells, 21 plates	S-103f, continuous torque 4 speeds ahead, 2 reverse
7,000-lb. dump	2 couple-gear wheels with one 2-hp motor in each wheel.	44 WT cells, 21 plates	G. E. special
7,000-lb. platform and stake...	1—No. 1022, 4 hp, 85 volts, 40 amp., 1200 r.p.m.	44 WT cells, 21 plates	S-103 F
10,000-lb. platform and reach...	1—No. 1030, 5 hp, 85 volts, 50 amp., 850 r.p.m.	44 WT cells, 25 plates	S-103 F
10,000-lb. platform and windlass.	1—No. 1030, 5 hp, 85 volts, 50 amp., 850 r.p.m.	44 WTX cells, 31 plates	S-103 F

NEW YORK RAILWAYS MOTOR TRUCKS—EMERGENCY WAGON WITH FENDER AND WHEELGUARD COMBINED, ALARM BELL, ETC.; WAGON FOR TRANSFERS AND STATIONERY etc. For convenience in description these general features are summarized in Table I, which gives the maximum speed and mileage which obtain when the vehicles are loaded to one-half their rated capacity and the run is made on hard level roads.

The motors are all of the General Electric series-wound automobile type with Hess-Bright ball bearings. The electrical equipment for each class of vehicle is given in Table II and the general dimensions in Table III.

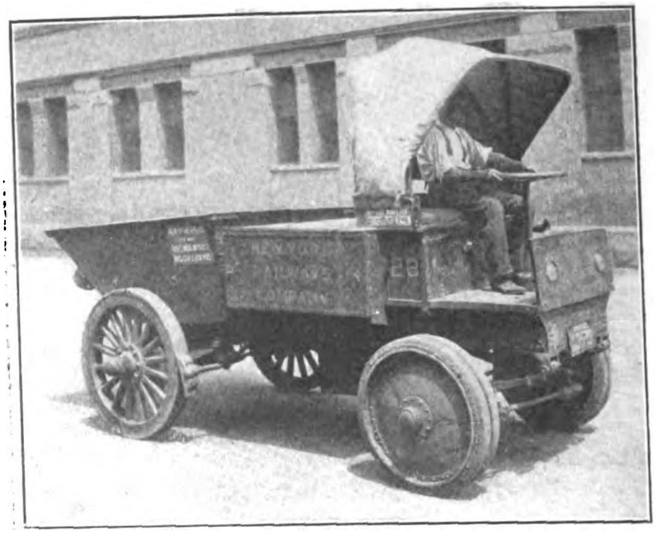
EQUIPMENT

All batteries are of lead type, equipped with waterproof covers and means for ventilation in summer. The minimum clearance between the ground and the bottom of the battery box when the truck is loaded is 8½ in. to 12½ in. The capacity of the 44-cell battery on the 4000-lb. emergency truck is 250 amp-hr., when discharged at 42 amp, and 200 amp-hr. when discharged at 56 amp. Its normal charging current is 30 amp, its maximum charging voltage, 115, and its weight, 1970 lb. The WTX type mentioned in the tables is a thin plate, high-capacity design.

The safety vehicle cut-out switch is of railway drum controller type and has three points: running, neutral and charging. Each wagon also carries a Sangamo ampere-hour meter of proper capacity with resetting device and zero contact for circuit-breaker trip. The circuit breaker is of 50-amp or 100-amp (for 7000-lb. and 10,000-lb. wagons) capacity, single-pole, double-break with shunt coil cut-out.

The controller compartment under the seat is of fireproof construction, and in this are mounted the controller, safety vehicle cut-out switch and meter. Standard electrical conduit is used throughout. The motor leads are connected to the vehicle wiring by a standard Westinghouse connector with which no set screws are used. The resistors are of railway type and are protected by a ventilated cover. The charging receptacles, which are of 100-amp capacity are standardized to receive the charging plug of public charging stations, so that there is practically no likelihood that a truck would ever be stranded for lack of energy. Two electric dash lamps and one electric tail lamp are furnished with each truck.

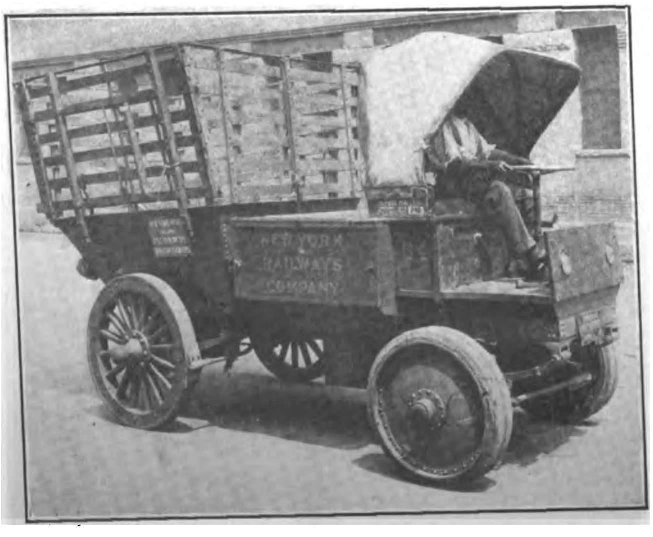
The frames of all trucks, except the 4000-lb. emergency and 7000-lb. steel dump, are of 3-in. rolled steel channels, braced with cross-channels reinforced with gussets. The other trucks have 5-in. members. The battery compartment is suspended on three heavy frames, upon which are fastened the angle-iron slides of the battery. The sides of this compartment are covered with sheet iron. The battery compartment doors are of wood.



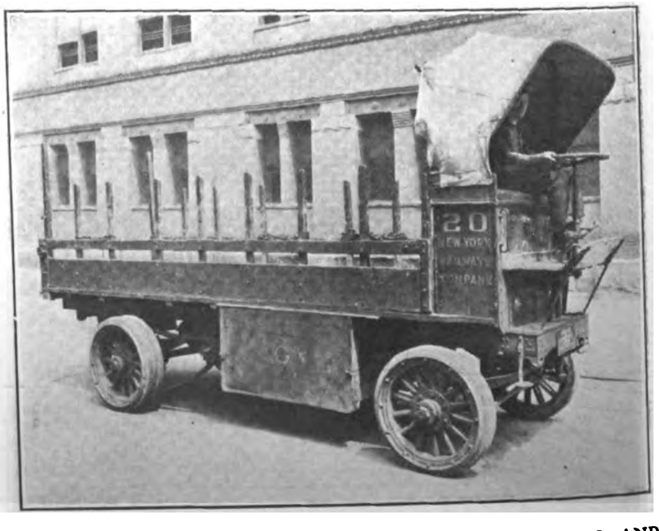
NEW YORK RAILWAYS MOTOR TRUCKS—7000-LB. DUMP WAGON

All countershafts are fully housed and mounted on anti-friction bearings. The differential is of fully inclosed design, with spur gears upon which a large Morse chain gear is mounted. The chain between the motor and countershaft is also fully inclosed. The springs, front and rear, are of the half-elliptic type with nib construction and with bronze bushings in the eye. On the 7000-lb. dump type wagon, however, there are half-elliptic springs at the front and quarter-elliptics at the rear.

All wheels are of demountable heavy artillery type placed on Timken roller bearings throughout, except that the front wheels of the dump trucks are of the type made by the Couple Gear Freight Wheel Company with solid rubber tires, while the rear wheels are of the standard steel-tired type as used on horse-drawn wagons. The front axle and steering knuckles of the 1000-lb. wagon are drop forgings of special heat-treated steel; the front axle is of square section. On the 2000-lb. wagons the knuckles are of chrome vanadium steel. On the 4000-lb. emergency, 7000-lb. platform and both 10,000-lb. wagons, the front axle is of chrome vanadium steel, round section, with end castings of chrome vanadium steel for carrying the steering knuckle and spring seat. The steering knuckles are drop forgings of chrome vanadium special heat-treated steel.



NEW YORK RAILWAYS MOTOR TRUCKS—7000-LB. RUBBISH WAGON



NEW YORK RAILWAYS MOTOR TRUCKS—PLATFORM AND STAKE WAGON WITH SIDE BOARDS

On the 7000-lb. dump wagon the front axle is of the couple-gear type having two driving motors, which also act as steering wheels.

The rear axle of the 1000-lb., 2000-lb., 4000-lb., 7000-lb. platform and 10,000-lb. wagons is of chrome vanadium steel of round section with crucible steel castings for the spring seat and brake anchorage. The rear axle of the 7000-lb. dump wagon is of the standard horse-drawn vehicle type with plain bearings.

All steering gear is of the pinion and sector type, with hardened and ground steel bushings and pins for all steering connections.

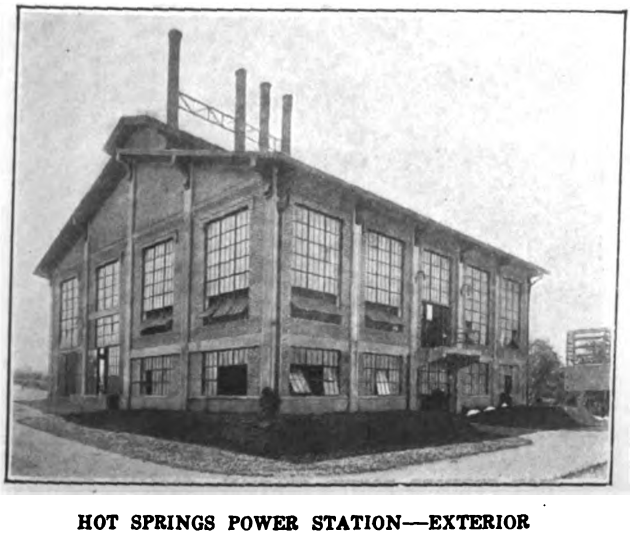
In general the service brakes are of the internal expanding type in the rear wheels. The emergency brake is of the contracting band type operating upon a brake band which is attached to the countershaft sprockets. The brakes are operated by means of pedals located on either side of the steering post. On the 7000-lb. steel dump wagon the service brake is of the contracting band type installed on the front wheel and the emergency brake operates upon the steel tires of the rear wheels.

All of the vehicles, except the emergency wagon, are fitted with two types of protective storm hoods for the drivers. All trucks except the one 1000-lb. and the three 2000-lb. types have canvas hoods, the remainder, with the exception of the emergency truck, being furnished with a covering formed by the forward projection of the body structure. All wagons, except the emergency type, have front and side curtains to afford protection against the weather.

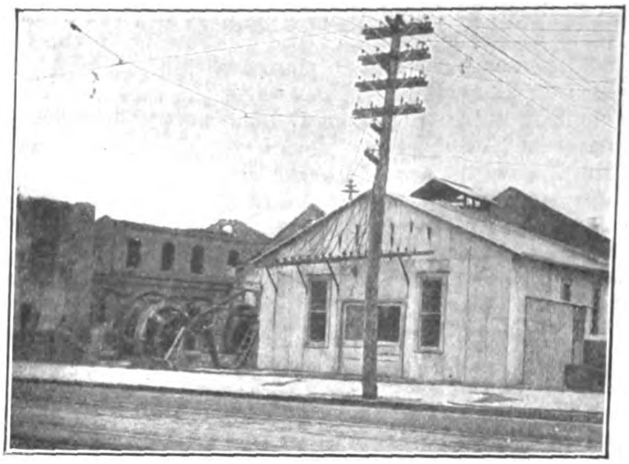
The character of the service rendered by these trucks has been generally satisfactory up to the present time, except during almost unprecedented weather conditions encountered last winter when blizzards made the streets practically impassable. Under these conditions the trucks failed to give continuous service.

Rapid Power Plant Construction at Hot Springs

The Citizens' Electric Company, Hot Springs, Ark., a subsidiary of the Federal Light & Traction Company, New York, has the distinction of breaking all previous records in constructing its new 2500-kw generating plant within 115 days after the destruction of its old station by fire Sept. 5, 1913, exactly one year ago. The old plant and several miles of feeder and distribution lines radiating therefrom were in the path of the conflagration which swept Hot Springs that September day, devastating nearly one-third of the city—an area of fifty-five blocks—and crippling all electric service, including that of the Hot Springs Street Railway Company, an affiliated corporation. Accounts and news of the damage caused by the fire were published in the ELECTRIC RAILWAY JOURNAL for Sept. 13 and Oct. 4, 1913.



HOT SPRINGS POWER STATION—EXTERIOR



HOT SPRINGS POWER STATION—RUINS OF BURNT PLANT, AND EMERGENCY STATION

Before the fire was out at Hot Springs, the New York office of the Federal Light & Traction Company had become a scene of intense activity. W. A. Haller, general superintendent and chief engineer of the Federal Light & Traction Company, started for Hot Springs on the afternoon of the fire, even before the destruction of the power station was reported. He reviewed the ruins and quickly outlined plans for the restoration of temporary service and the construction of a new station. Meanwhile the executive and purchasing departments began to rush new equipment to the stricken city, and manufacturing companies were called upon to aid. Telegrams were sent to all parts of the country tracing turbines and other equipment, either new or second-hand, which could be bought and hurried to Hot Springs. Rush orders were also placed for transmission, trolley and feeder wire.

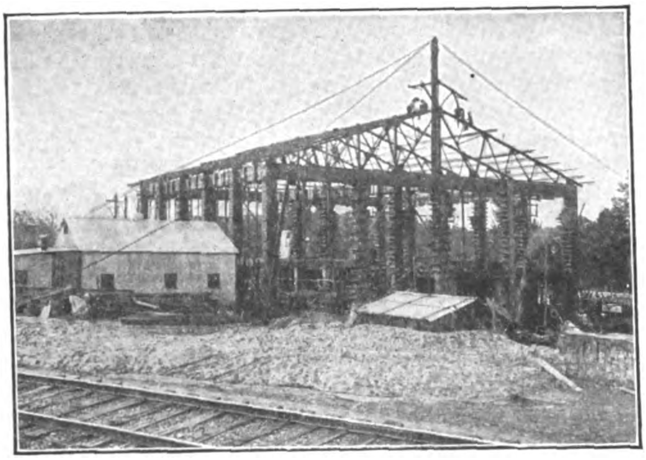
Within ten days after the disaster emergency service was furnished the city, which had not yet recovered from the demoralizing effects of the fire, and coincident therewith the designs for a new station had been developed sufficiently to permit ordering apparatus and material for the construction of the new plant. From this new plant regular service was established on Jan. 1, 1914, just 115 days after the fire. The new station, although built in this record-breaking time, is well arranged and presents the appearance of a beautiful and efficient piece of construction.

As the old property had acquired a value which made it undesirable to reconstruct the generating station on that site, the company's representatives selected and purchased a tract of land about a mile south of Hot Springs on the "Iron Mountain" railroad and the Hot Springs Creek. Although the new site is not so near the load center of the system as was the old plant, it is admirably located for the future since the city is rapidly extending in that direction.

Building plans for the new station were started on Sept. 10, all the engineering and designing being done on the job so that actual construction could be carried on in parallel with the drafting, thus avoiding delay. Ground was broken on Sept. 16, a work office was constructed, and temporary electric service lines were erected to supply energy for lighting and motors on the job when emergency service from the temporary station was restored on Sept. 15. Meanwhile rush orders for immediate shipment had been sent out for equipment and building material.

By Sept. 23 foundation forms were in place and concrete was being poured. The concrete up to the main engine-room floor was all poured within two weeks, and by Oct. 21 the roof trusses, with the exception of the monitor, were in place. Boilers were being installed early in November and steam was raised and some of the apparatus had a preliminary try-out on Dec. 10. The station was operated intermittently thereafter until Jan. 1, when the electrical equipment was in shape for regular service. From that time on energy for lamp and motor service has been delivered regularly from the new station. The 1250-kw generator and the 300-kw motor-generator set in the temporary station were then transferred to the new plant, making the total rating of the station 2250 kw.

The removal of the 300-kw railway motor-generator from the temporary station to the new station was a feature worthy of note. The second motor-generator had not arrived in Hot Springs at the time the new station was ready for operation; therefore it became necessary to remove to the new station the machine then being operated in the temporary station. To secure the least possible interruption to the railway service, the motor-generator was shut down at midnight Jan. 14, disconnected and transported 800 ft. on rollers, there loaded upon a flat car and transferred to the new station, installed, connected and placed in operation by 7.15 the following morning, the total time consumed being six hours and forty-five minutes.

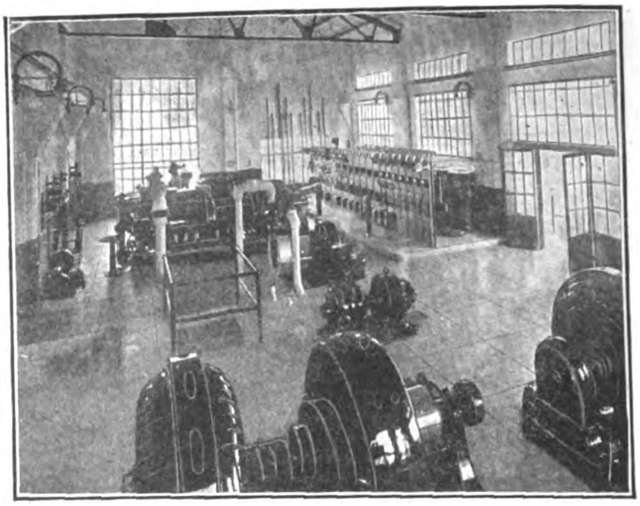


HOT SPRINGS POWER STATION—STEEL FRAME ERECTED IN THIRTY-TWO DAYS

DESCRIPTION OF NEW STATION

The new station is a reinforced-concrete structure with brick curtain walls, steel sash and doors fitted with wired glass throughout, and steel roof trusses carrying a roof consisting of two layers of corrugated galvanized iron with a layer of 1-16-in. asbestos placed between to prevent sweating.

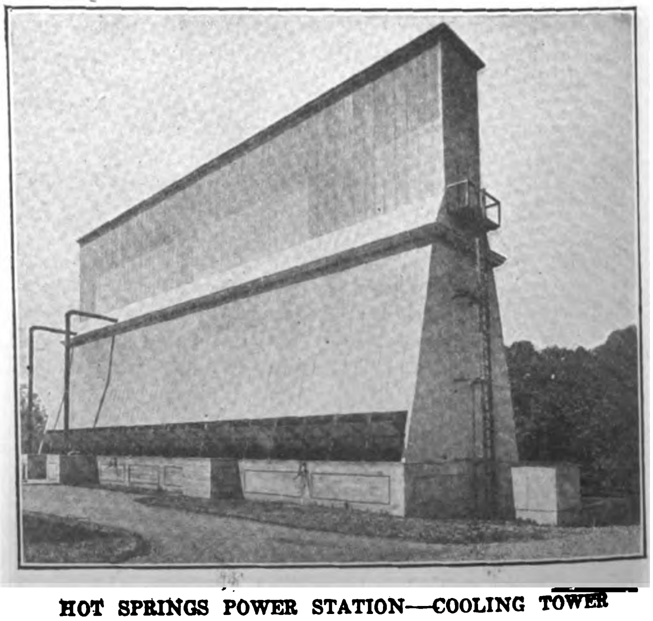
The present equipment of the new station consists of two 2300-volt turbo-generator units rated at 1000 kw and 1250 kw respectively, two 300-kw synchronous-motor-generator sets, one 30-kw induction-motor-driven exciter, one 30-kw marine-engine-driven exciter, four 316-hp Heine boilers equipped to burn gas or coal, a 20-ton Whiting crane, and the usual auxiliaries. The motor-generator sets operate at 2300 volts. The switchboard was constructed, assembled and shipped thirty days after the order was given. Space has been provided in the station for the addition of two more boilers and one more turbo-generator set. All of the electrical equipment, except the motor-driven exciter, was furnished by the General Electric Company. The exciter was built by the Westinghouse Electric & Manufacturing Company.



HOT SPRINGS POWER STATION—INTERIOR OF ENGINE ROOM

As the water in the creek adjoining the plant comes from an overflow of the famous hot springs and is too warm for condensing purposes, besides containing considerable sewage, it was necessary to erect a cooling tower. This tower, which is of the natural-draft type, consists of a long trough at the top connecting with projecting laterals which are slotted to allow water to trickle down over the cooling surfaces. The latter consist of square wooden bars supported in a horizontal position with one diagonal in the vertical position. By arranging the bars in this position a larger effective cooling surface is presented to the water, which is also assisted in its downward course by the sharp edges of the bars being lowermost.

Each boiler is equipped to burn either gas or coal. Eleven Gwynn gas burners are employed under each boiler for burning gas, and two Jones underfeed stokers are installed under each boiler for coal firing. The gas nozzles are arranged above the furnace doors so that they do not interfere with coal combustion, it being possible to carry on both methods of firing at the same time. When only gas is being burned the grates are kept covered with ashes to prevent their being fused by heat reflected from the furnace arch. Natural gas is piped into this plant from the Caddo-Louisiana fields.



HOT SPRINGS POWER STATION—COOLING TOWER

Electric Railway Trade Outlook

Opinions of Electric Railway Manufacturers Regarding Present Commercial Conditions, the Probable Effect of the Present War on Domestic and Foreign Trade and the Proper Means for Improving our Trade in South America—Experiences of Americans in the War Zone

As an amplification of the interviews which the ELECTRIC RAILWAY JOURNAL procured with officials of the General Electric Company, the Westinghouse Electric & Manufacturing Company, the Pearson Engineering Corporation and the J. G. White Engineering Corporation and published in its issues of Aug. 22 and Aug. 29, opinions of additional electric railway manufacturers have been requested during the last week both personally and by letter. Each company has been asked for its ideas regarding the effect of the present war with reference to the receipt from abroad of materials necessary for its manufactured articles, the possibility of producing in this country materials not obtainable abroad, and also the chance of introducing substitutes for any unobtainable materials without any substantial increase in the cost of production. Furthermore, advice has been sought in regard to the possible interference caused by the war with both the domestic and the foreign business of the various companies and in regard to the special steps being taken to improve South American trade. The answers of the manufacturers on the above points follow in part.

United States Electric Signal Company, West Newton, Mass.—Roland F. Gammons, second vice-president, believes that the sales of his company must be affected adversely to some extent as long as the unusually high rates of interest for capital continue, for signal apparatus is charged by the purchaser to capital account, and the outlook is poor for electric railways in the immediate future to secure new capital for permanent improvements. The foreign business of the United States Electric Signal Company has been principally with the countries now at war. Consequently the company expects no further trade there as long as present conditions prevail. The company has completed arrangements, however, for representation in one of the principal South American countries and is also seeking suitable connections in other countries. South American trade heretofore carried on by the company has been confined to Brazil, where the principal railway systems use its material. Mr. Gammons states that he does not expect a large volume of business in South America but is hoping to secure some increase and through the present opportunity to establish relations which will be useful in the future as the country develops.

The Tool Steel Gear & Pinion Company, Cincinnati, Ohio.—E. S. Sawtelle, assistant general manager, says that the war situation is interfering to a considerable extent with his company's foreign business, since at the present time it has a good sized trade developed with England, France and Germany. At the present time it is furnishing to English manufacturers a large number of gears and pinions used on the new motor equipment for the electrification of some of the large steam railroads. Several carloads of this material caught between Cincinnati and New York at the time the war became acute are still held in New York and cannot be forwarded on account of shortage in shipping facilities. German business will be entirely paralyzed while the war lasts, but English and French business will right itself and possibly improve as soon as the seas are clear. The company is taking general steps to increase its South American business in expectation of a considerable increase.

National Carbon Company, Cleveland, Ohio.—Officials of this company state that preparations are being made to take care of all the carbon business that comes from those countries which have been depending upon Europe for their supplies. That they must look elsewhere for carbons is a foregone conclusion and, without doubt, a demand will be made upon the United States to meet their needs. As far as the battery business is concerned, the situation remains unchanged. The company has had a good battery business from almost all foreign countries for some years, and the war can make but little difference with the countries not now affected by it.

Ohmer Fare Register Company, Dayton, Ohio.—John T. Ohmer, president of the company, advises the ELECTRIC RAILWAY JOURNAL that material used by his company is produced in this country with the single exception of rubber, which is used in limited quantities. Mr. Ohmer says that domestic business may show a slight depression on account of the false impression of a few operators that the acquisition of Ohmer fare registers will increase operating expenses. As regards foreign business, for several years the company has not bid for any except in the Dominion of Canada.

Niles Car & Manufacturing Company, Niles, Ohio.—This company is concerned with the European war only through the general depression resulting from financial uncertainty and the reluctance of bankers to finance new railways until the war takes some definite turn. No material used by the company is affected. The company does no foreign business except with Canada, which it obtains when Canadian builders are unable to handle the business, and it expresses a lack of desire to obtain foreign trade.

Standard Paint Company, New York.—C. E. Smith, manager of electrical department, states that the war has increased this company's cost of manufacturing insulating materials by advancing the price of certain imported raw materials. In some instances it has been possible for the company to make use of locally manufactured articles, but not in the case of standard staple commodities. The products of this manufacturer in the electric railway field are employed chiefly for the insulation of motors and for repair work in car repair shops. Since the larger part of this use is required constantly for maintenance and repair work it is not believed that the war will reduce the demand for insulating materials in this country to any great extent, except as the decrease in new equipment will lessen the amount thus used. The foreign business of the company has stopped. The London factory has been shut down, while everyone has left the Hamburg factory for the war except a few directors. Trade with the Orient has decreased a great deal because of the heavily increased insurance rate. Considering the discontinuance of German trade with South America and with the prospect of better banking facilities with the United States, the company anticipates a fairly successful business from this source through its special representatives.

Pyrene Manufacturing Company, New York.—H. W. Chapman, office manager, states that the business of this company has not been affected by the war in regard to procuring the materials necessary for the manufacture of its fire extinguisher, Pyrene, because its products are all obtained in this country. The war will interfere with domestic business only indirectly, as a result of the general retrenchment. Before the war a large number of fire extinguisher sales were made to England and the Continent, through the London office. This European business has nearly entirely fallen off, though a temporary stimulation due to the war has arisen with the British and French governments owing to the desire on the part of the armies representing these countries to equip with extinguishers their motor cars and aeroplanes. The company carries on a considerable foreign business with China, Japan, India and South Africa. A marked falling off in this is believed to be inevitable. The South American and Australian business of the company is represented by Chipman, Ltd., of New York. The likelihood of any increased business from this quarter is questioned, owing to the scarcity of money with which to buy.

Wasson Engineering & Supply Company, Milwaukee, Wis.—F. A. Wasson, general manager, states that his company uses no imported materials in the manufacture of its apparatus. It was making plans for European representations before the war, but negotiations have now been indefinitely postponed. By coming to the rescue financially of some of the neutral nations now left in a helpless condition by the withdrawal of commercial and financial support, the United States would establish a prestige, the benefit of which would be permanent. As a solution of the present situation Mr. Wasson offers the following suggestion: "Remain neutral at all events; provide an adequate merchant marine; ascertain the needs of neutral nations and supply them where practical; decide what business is wanted and then go for it; have absolute confidence in American government, American industries and American prosperity, and act accordingly."

The Elyria Iron & Steel Company, Elyria, Ohio.—According to J. L. Varner, secretary and assistant treasurer, this company is concerned only in a general way with the probable expansion of the commerce of this country. Its product as well as the raw material from which it is made will not be affected by the war situation, for the company purchases none of its supplies from Europe and does not export any of its materials. It expects its business to increase simply through local requirements.

The Wheel Truing Brake Company, Detroit, Mich.—J. N. Griffin, president and general manager, states that inasmuch as his company uses domestic material his business will not be affected by the war so far as raw materials are concerned. American domestic business is concerned only to the extent that our country becomes directly involved in the European struggle. There will be at least a temporary suspension in the European trade, but South American trade is improving.

Monarch Refillable Fuse Company, Buffalo, N. Y.—This company believes that the war will interfere with its foreign business with Germany and her allies but that the trade with England and France will be carried on as usual with a certain present drop. The company had directed its attention to South American business before the war but is now studying conditions there even more intently. If the United States manufacturers develop the manufacture of goods now made in Europe they can secure and hold the business of not only South America but also Africa and other foreign countries.

Dossert & Company, New York.—According to a statement made by H. B. Logan, president, war conditions have not as yet affected the company adversely. On the contrary, orders were received in such gratifying volume during the latter part of July and the first half of August that the company now has more unfilled orders on hand than at any time during the past fifteen months. All the materials used in the solderless connectors of the company are produced in this country and no embarrassment is suffered from the cutting off of imports. No estimates can be made of the effect of the war on the company's foreign business, which is chiefly in the western hemisphere.

Tubular Woven Fabric Company, Pawtucket, R. I.—Speaking for this company, William Kennedy says that with the general increased business which must come to America as a result of the present war a new impulse will be felt that must naturally cause the company's business to expand. All the raw material used is obtainable in this country, and it is believed that the coming year will be the biggest in the company's history.

Diamond State Fibre Company, Elsemere, Del.—The fiber for electrical insulation manufactured by this company is made from cotton rags and hemp twine, 80 per cent of which is imported, principally from the countries involved in the present European war. A large quantity of such raw material is produced in America and other countries but not enough to meet ordinary demands. Prices have already gone up, and a further advance is mentioned. While eventually the war will benefit the company's domestic business, no improvement is expected for several months, as a large percentage of the company's products was exported to Germany and other foreign countries and the loss of this business has been severely felt. It is stated that the company intends to push vigorously the sale of its product in all South American countries.

Hope Webbing Company, Providence, R. I.—This company thinks that the war should not interfere materially with its domestic business, and its foreign business is limited and not likely to be much reduced by the foreign disturbance. It feels that it is likely to gain more business in Canada than is lost abroad, and can also increase its export business in South America.

Dielectric Manufacturing Company, St. Louis, Mo.—According to J. J. Kessler, president, raw materials for insulation, such as oils, gums and waxes, have increased in price. None of these are produced here and most of them are incapable of being so produced. It would not be possible to produce substitutes except to a limited extent. Mr. Kessler believes that the war will not interfere with his company's domestic business to any considerable extent. In regard to foreign trade he says that it will materially increase our export business on account of the new trade possibilities in territories where we have heretofore been unable to compete.

Stackpole Carbon Company, St. Mary's, Pa.—This company's sources of supplies abroad will be able to fulfil its contracts for raw materials in spite of the war, but the company is unable to say how long this condition will last because it is obliged to look for manganese in belligerent countries. There is no substitute for manganese in the manufacture of dry cells. Mr. Stackpole was optimistic in regard to the increase of the company's business, both at home and abroad. The only step being taken to increase South American business is the enlarging of advertising space in publications printed in South American languages.

Tower Specialty Company, New York.—This company does not export to Europe but builds its superheaters in Europe. This business, of course, is very seriously affected by the war. Careful investigations have been made in regard to means for increasing business in South America, but no definite steps have as yet been decided upon. One difficulty to be overcome in securing this business is the fact that European manufacturers have educated South American purchasers to long deferred payments. The company's domestic trade will be injured by the war only to the extent that the business of the customers is affected.

Nachod Signal Company, Philadelphia.—The effect of the European war upon the sale of automatic signals has been a temporary postponement of business. The present unsettled condition of business will continue for some time, but enough business will be secured to cause no serious stagnation. The company has already been soliciting South American business in various ways. The prospects of improving trade in this direction are bright, but the possibility of any extensive business being developed in South American countries is seriously questioned.

Thayer & Company, Inc., New York.—This company has not yet felt any trade depression caused by the European war. During the last three months orders have shown a marked increase in number and size and territory represented, regardless of the reported curtailment in the expenditures of electric railways. This is attributed solely to the special character of the product. Optimism is expressed in regard to the opportunity offered in South America.

L. S. Brach Supply Company, New York.—As yet it is impossible to determine whether the war or domestic conditions are affecting this company's business, but general railroad work is at low ebb and there does not seem to be any immediate outlook for improvement. There are no materials that have been purchased abroad which could not be supplied in this country. The war will not interfere with domestic business if financial conditions here can be properly adjusted. As yet no special attempts have been made to increase the export business to South America.

J. W. Paxon Company, Philadelphia.—S. C. Bougher, treasurer, says that the European war affects all the departments of the company, on account of the use of foreign raw material. It is not seriously disturbed, however, by the lack of imports or exports. Foreign export trade is not catered to and there is very little in the company's business that is attractive abroad. Sales can be made more readily to South America, however, and closer relations are being established in that country.

Green Engineering Company, East Chicago, Ind.—P. Albert Poppenhusen, president, says that inasmuch as steel and iron enter into the manufacture of the company's chain grate stokers, business has not yet been affected by the cutting off of foreign supplies, although it is presumed that the price of steel will advance. Raw materials can be obtained from other countries than formerly and can also be produced in this country, but this would take some time, during which period much business cannot be anticipated. The companies should be able to introduce substitutes for such material without substantially increasing the cost of production. The war will not seriously interfere with exports for these are made only to Japan, Africa and Australia and shipping there is protected by the British. No steps have been made to increase export business to South America, for it is believed that coal conditions there oppose.

In addition to those companies quoted above, this paper has interviewed a number of companies prominent in the electric railway business, who were willing to express their opinions but did not wish their names quoted. One large manufacturing company, which does not desire to have its name used, believes that foreign business will be largely cut off until the end of the war, and many changes may be made necessary in the agency arrangements of a great many American manufacturers. This same company believes that the export business to South America will not amount to anything immediately in view of the predominance there of British and German capital. Later, however, South American countries will have to go to America, for Germany and Great Britain will be absolutely cut off.

Another company, in discussing the rubber situation said: "The rubber market is one controlled by London, and the supply of crude rubber in the United States is not up to the standard. This will be overcome to a certain extent as long as the European government keeps the routes of commerce open. It is not possible to obtain rubber from sources other than the countries involved in the war. In a great many instances, however, substitutions can be used in place of rubber."

A third manufacturer, after being established in South American trade for sixteen years, expects business to be increased to the extent that there is interference with the competitive materials shipped from Europe.

MR. SHONTS ON PARIS CONDITIONS

Theodore P. Shonts, president Interborough Rapid Transit Company, New York, had an interesting experience in Paris, where he arrived on Sunday, Aug. 2, soon after war was declared. He came on what proved to be the last train from Switzerland for several weeks. He found at the railroad station that all of the conveyances for driving to the hotels had been commandeered by the military authorities and that the baggage room was in such great confusion that he could not get out his baggage. Finally he found an old express wagon and induced the driver by a large fee to take him and his party to their hotel. In the morning he returned to the station to get his baggage, and found the place surrounded by soldiers and no one was allowed to enter. Finally, through the courtesy of a member of the French House of Deputies, the trunks required by him and the members of his family were obtained. During the week in which he remained in Paris Mr. Shonts served on the relief committee appointed by Ambassador Herrick to help Americans to leave France.

Commenting on the general situation in the city, as observed by him, he said to a representative of this paper that the work accomplished by the French government in mobilizing its troops was marvelously well done and the spirit of the French people indicated a sober sense of the perilous position in which they were put and a firm resolution to accomplish all that was possible for a brave nation to do. Although the troops were constantly marching through the city military bands were very few. The streets exhibited a deserted appearance, partly because most of the shops were closed and partly because in all of those which were open most of the employees had gone to the front. The Metropolitan underground railway in Paris was in operation but with greatly reduced service, and ran no trains after 8 p. m. All of the restaurants were ordered closed at the same hour.

In London, where Mr. Shonts arrived on Aug. 15, matters had a more natural appearance, although there seemed to be fewer buses on the streets. This may have been due to the vehicles being commandeered by the government or possibly because of the lighter traffic due to the war.

MR. SWOPE'S EXPERIENCES

Gerard Swope, vice-president Western Electric Company, contributes a very interesting article on his European experiences to the current issue of the *Western Electric News*. He was in Antwerp when the war broke out, and the Belgium government immediately requisitioned space to house 500 soldiers at the factory of the Bell Telephone Company in that city. In the meantime many of the workmen there and in the company's factory in Paris were called out, and owing to the difficulty of drawing currency to meet the payrolls both factories were closed down. It was soon found that unless the factories could operate, even though on part time, the want and distress due to the war would be much increased by lack of employment, so that both factories were soon reopened although, of course, with largely decreased forces. The workmen are being paid in checks which the company has promised to redeem as soon as possible at their face value. The English factory is still operating under conditions that are nearly normal.

Mr. Swope arrived in New York on Aug. 22 and has heard by cable that on Aug. 24 about 500 employees were still working in the Antwerp factory and about 200 in the Paris factory. The prospects were that these factories could continue at work for some time without the receipt of further raw material. The conditions at the London factory are nearly normal.

AMERICAN ROLLING STOCK EXPORTS.

The table published herewith shows the exports of American electric railway rolling stock to the countries of the entire world for the years 1908 to 1912, inclusive, and for the first ten months of 1913. For the last mentioned period, Brazil led the list with an importation of rolling stock amounting to $2,502,572, far ahead of the only other serious competitors, Cuba, with $722,188, Canada with $564,258, Mexico with $186,933, Europe with $185,312, and Australasia with $124,016. The most interesting feature in the whole table is the fact that Brazil, with its total of $2,502,572, took more than one-half of the total rolling stock exports for the 1913 period, probably because the two largest electric railways in Brazil make most of their purchases in the United States. On the other hand, in Argentina, Peru and Chile, where English and German capital predominates, there were exports of only $87,905, $68,124 and $29,034, respectively.

Foreigners' Patents in England

The London Board of Trade made an announcement on Aug. 22 in regard to patents owned by subjects of countries with which England is at war, as follows:

"The Board of Trade has issued rules under the patents, designs and trade-marks (temporary rules) act, 1914, regulating the procedure for the avoidance of suspension of any patent or license or trade-mark granted, the proprietor of which is a subject of any state at war with His Majesty, where an application is made to the board for this purpose. The board must be satisfied that the applicant intends to manufacture the article concerned or carry on the patented process, and also that it is in the public interest that this should be done. The rules provide also for the avoidance or suspension of any application for a patent or trade-mark by a subject of an enemy state."

Illinois Association May Send Ship to South America

Under the chairmanship of E. N. Hurley of Chicago the foreign trade committee of the Illinois Manufacturers' Association has been very active in its efforts to expand trading relations between business men in South America and in the United States. The association has warmly seconded the efforts of its committee and has decided to go ahead with the project of chartering a small steamship, say of about 5000 tons, to go from the United States to South American ports with samples of American machinery and manufactured goods of all kinds. It is planned to fit up the main deck of the boat and also portions of the hold as an exposition of manufactured products suitable for the South American market. Salesmen, and possibly saleswomen as well, will be on board to explain the exhibits, and it is planned to make stops of perhaps several weeks' duration in the principal South American ports, on the East Coast at all events and possibly on the West Coast. A special effort will be made to show the goods of smaller manufacturers, as it is felt that a co-operative effort such as this should appeal particularly to those American producers who have not the great resources of the large manufacturing concerns. Novelties and specialties of all kinds are especially desired. It is quite possible that there will be room on the boat for non-members of the association who desire to take advantage of the trip. Electrical manufactures, among other things, are desired. John M. Glenn, secretary of the Illinois Manufacturers' Association, 76 West Monroe Street, Chicago, will no doubt be glad to give further information about the plan.

TABLE—SHOWING EXPORTS OF ELECTRIC RAILWAY ROLLING STOCK FROM THE UNITED STATES TO VARIOUS FOREIGN COUNTRIES.

	1908	1909	1910	1911	1912	First Ten Months 1913
Europe	$116,884	$72,126	$58,803	$121,591	$112,770	$185,312
Canada	113,915	135,559	112,155	266,473	365,677	564,258
Central America	168,920	103,001	154,606	156,088	54,353	34,732
Mexico	298,019	130,755	187,980	496,741	125,004	186,933
Cuba	155,597	246,630	344,136	549,189	590,420	722,188
Other West Indies	18,054	18,281	31,069	40,359	59,936	23,219
South America:						
Argentina	249,038	111,290	214,691	55,189	30,313	87,905
Bolivia	87,144	13,521	270	....	784	16,691
Brazil	389,778	408,480	134,178	241,098	416,841	2,502,572

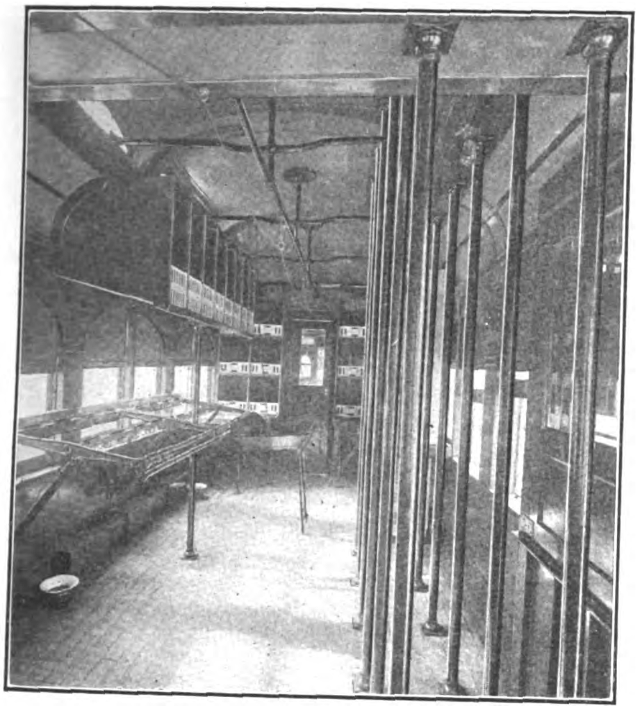
All other	29,424	2,575	......	687	6,463	5,539
Total	$2,286,755	$1,477,279	$1,522,817	$2,782,063	$2,476,646	$4,646,881

Texas Traction Carries U. S. Mail

On Aug. 15, 1914, the Texas Traction Company, Dallas, Tex., put in service the first of two cars which will be used as United States railway post-offices on its Denison-Sherman-Dallas interurban line. This is the first service of its kind to be inaugurated on the interurban lines in the Southwest, and a second car will be equipped in the near future. The territory served by this line desired the interurban railway mail distribution, because of its more frequent service. It is believed that this will be a great help to every town and city between Denison and Dallas, since it assures mail delivery between any of the points on the day it is written.



TEXAS TRACTION MAIL CAR—INTERIOR OF MAIL ROOM

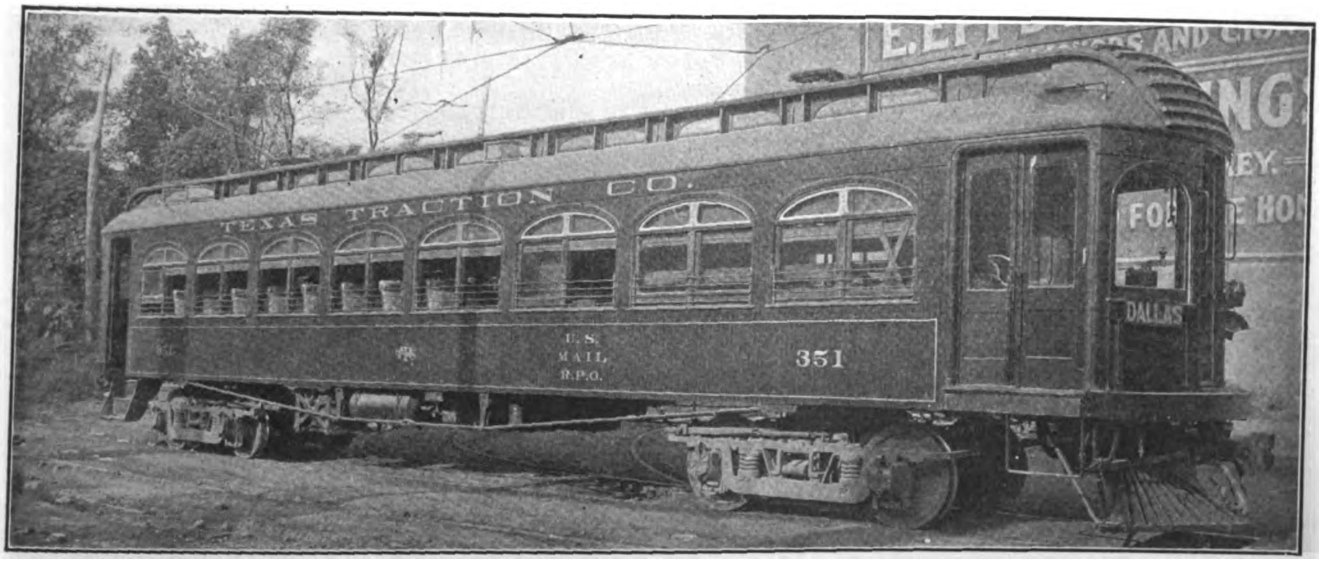
In order to contract for this mail service it was necessary for the traction company to remodel two of its standard passenger coaches into railway post-offices. The rear end of this car is a regulation passenger compartment, while the front end is equipped as a United States railway mail car. Exterior and interior views of this car are shown in the accompanying illustrations. The mail room is equipped with standard paraphernalia used in the distribution and handling of United States mail, which includes sorting counters, registered mail sack compartments and mail sack holders. This compartment will at all times be in charge of two United States mail clerks.

The initial schedule for this interurban railway postal service includes two trains each way daily, leaving Denison at 5:50 a. m. and 3:50 p. m. respectively, and leaving Dallas at 11 a. m. and 8 p. m. respectively. The run, which is approximately 86 miles, will be made in about three hours and forty minutes, and the two mail clerks will handle and distribute mail en route.

Montana Public Service Commission Report

The sixth annual report of the Railroad and Public Service Commission of Montana for the year ended Nov. 30, 1913, has recently been issued. The book covers the orders from the commission in regard to station and train service, tariffs, rates, charges, train accidents and personal injuries, as well as the activities of the Public Service Commission. By the 1913 act of the Montana Legislature the Board of Railroad Commissioners was made ex-officio the Board of Public Service Commissioners of the State. The commission report contains the full text of the Public Service Commission law and the rules and practices of that body. The first annual report of the Public Service Commission will be made for the year ending Nov. 30, 1914. The chief work of the commission thus far has been the perfection of its organization, although it has prepared and placed in the hands of all public utilities a standard accounting system effective July 1. There is presented a list of the public utilities coming under the jurisdiction of the commission and also an outline of the electrification of the Chicago, Milwaukee & St. Paul Railway in Montana, prepared by C. A. Goodnow, assistant to the president, and a story of the electrification of the Butte, Anaconda & Pacific Railway, written by R. E. Wade, electrical engineer.

The directors of the Third Avenue Railway, New York, have recently authorized the construction of a printing plant for the printing of its own transfers. This is expected to result in the saving to the company of not less than $25,000 a year.



TEXAS TRACTION MAIL CAR—EXTERIOR VIEW OF CAR

Program for the A. E. R. A. Convention

Below Is Given the Complete Program for the 1914 Convention of the American Electric Railway Association and Its Affiliated Associations.

The annual convention of the American Electric Railway Association and its affiliated associations will be held, as last year, at Atlantic City, N. J. The exhibits and convention halls will be located on Young's Pier and the dates are from Monday, Oct. 12, to Friday, Oct. 16. The following program has just been completed and announced by Secretary E. B. Burritt. This is subject to revision.

PROGRAM OF AMERICAN ASSOCIATION

Tuesday, Oct. 13

9.30 a. m. to 12.30 p. m.

Registration and distribution of badges at booth, entrance to Young's Million-Dollar Pier.

2 p. m. to 5 p. m.

Annual address of president.
Annual report of executive committee.
Annual report of secretary-treasurer.
Announcements.
New business.
Reports of committees:
  (a) Subjects,
  (b) Education,
  (c) Special committee on joint use of poles.
Address on "Mooted Principles in Valuation," by Frank W. Stevens, chairman of the valuation committee, New York Central Lines, New York, N. Y.
Address on "The Organization and Functions of a Valuation staff" by H. C. Donecker, assistant general manager Public Service Railway, Newark, N. J.
Reports of committees (continued):
  (d) Company membership,
  (e) Company sections and individual membership.

Wednesday, Oct. 14

2 p. m. to 5 p. m.

Appointment of committee on nominations.
Reports of committees:
  (a) Changes in constitution and by-laws,
  (b) Relations with sectional associations,
  (c) Relations with manufacturers' association,
  (d) Electrolysis,
  (e) Company section medal,
  (f) Anthony N. Brady medal,
  (g) Ways and means,
  (h) Public relations.
Address on "Electric Securities from the Standpoint of the Corporation" by Calvert Townley, chairman board of directors Lackawanna & Wyoming Valley Rapid Transit Company, New York, N. Y.
Address on "The Aspects of Workmen's Compensation Laws" by Harry A. Bullock, secretary New York Municipal Railway Corporation, Brooklyn, N. Y.
Reports of committees (continued):
  (i) A. E. R. A. advisory,
  (j) Insurance.

Thursday, Oct. 15

2 p. m. to 5 p. m.

Reports of committees:
  (a) Compensation for carrying United States mail,
  (b) Federal relations,
  (c) Cost of passenger transportation service.
Address on "A Zone System of Fares in Practice" by R. B. Stearns, vice-president and assistant general manager The Milwaukee Electric Railway & Light Company, Milwaukee, Wis.
Reports of committees (continued):
  (d) Taxation matters,
  (e) Legal association,
  (f) 1915 convention.
Report of committee on nominations.
Election of officers.
Installation of officers.
Resolutions.
Unfinished business.
Adjournment.

PROGRAM OF ENGINEERING ASSOCIATION

Monday, Oct. 12

9.30 a. m. to 12.30 p. m.

Registration and distribution of badges at booth, entrance to Young's Million-Dollar Pier.

2 p. m. to 5 p. m.

Annual address of president.
Annual report of executive committee.
Annual report of secretary-treasurer.
Appointment of convention committees.
Reports of committees:
  (a) Constitution and by-laws,
  (b) Power distribution,
  (c) Standards (on recommendations contained in above report),
  (d) Electrolysis.

Tuesday, Oct. 13

9.30 a. m. to 11 a. m., joint session with Claims and Transportation and Traffic Associations.
Report of accident prevention board.
11 a. m. to 12.30 p. m., joint session with Transportation and Traffic Association.
Reports of committees:
  (a) Block signals,
  (b) Joint sub-committee on block signal rules,
  (c) Transportation-engineering.

Wednesday, Oct. 14

9.30 a. m. to 12.30 p. m.

Reports of committees:
  (a) Equipment,
  (b) Standards (on recommendations contained in above report),
  (c) Buildings and structures,
  (d) Standards (on recommendations contained in above report).

Thursday, Oct. 15

9.30 a. m. to 11.30 a. m., joint session with Accountants' Association.
Reports of committees:
  (a) Life of railway physical property,
  (b) Engineering-accounting.

11.30 a. m. to 12.30 p. m.

Reports of committees (continued):
  (c) Power generation.
  (d) Standards (on recommendations contained in above report).

Friday, Oct. 16

9.30 a. m. to 12.30 p. m.

Reports of committees:
  (a) Way matters,
  (b) Standards (on recommendations contained in above report),
  (c) Heavy electric traction,
  (d) Standards (on recommendations contained in above report).

General business.

Report of committee on nominations.

Election of officers.

Installation of officers.

Adjournment.

PROGRAM OF ACCOUNTANTS' ASSOCIATION

Monday, Oct. 12

9.30 a. m. to 5 p. m.

Registration and distribution of badges at booth, entrance to Young's Million-Dollar Pier.

Tuesday, Oct. 13

9.30 a. m. to 12.30 p. m.

Annual address of president.

Annual report of executive committee.

Annual report of secretary-treasurer.

Reports of committees:

(a) Standard classification of accounts,
(b) Interline accounting,
(c) Accounting definitions,
(d) Representing association at convention of railroad commissioners,
(e) Bureau of the census,
(f) Express and freight accounting,
(g) Committee on education.

Address on "The Education of To-day" by John R. Wildman, professor of accounting New York University.

Appointment of committees:

(a) Resolutions,
(b) Nominations,
(c) New business.

Wednesday, Oct. 14

9.30 a. m. to 11 a. m.

Report of committee:

(a) Overhead charges.

Addresses:

"Investment Bankers and Public Service Accountants" by H. S. Swift, treasurer West Penn Traction Company, Pittsburgh, Pa.

"The Accounting Treatment of Bond Discounts" by J. F. Fogarty, secretary The North American Company, New York.

11 a. m. to 12.30 p. m.

Joint session with Claims Association

Report of committee:

(a) Claim Accounting.

Thursday, Oct. 15

9.30 a. m. to 11.30 a. m.

Joint session with Engineering Association

Reports of committees:

(a) Life of railway physical property,
(b) Engineering-accounting.

(Accountants adjourn to accountants' hall.)

11.30 a. m. to 12.30 p. m.

Addresses:

"The Accounting Features of Valuation" by A. T. Smith, assistant chief division of valuation, Interstate Commerce Commission, Washington, D. C.

"The Accounting Treatment of Depreciation" by Robert Sealy, The North American Company, New York.

Report of committee on resolutions.

Report of committee on nominations.

Election of officers.

Installation of officers.

Adjournment.

PROGRAM OF CLAIMS ASSOCIATION

Monday, Oct. 12

9.30 a. m. to 12.30 p. m.

Registration and distribution of badges at booth, entrance to Young's Million-Dollar Pier.

2.30 p. m. to 5.30 p. m.

Annual address of president.

Annual report of executive committee.

Annual report of secretary-treasurer.

Reports of special committees.

Appointment of convention committees.

Paper on "How Investigations Should Be Conducted from a Legal Point of View, Having in Mind Defense as Well as Adjustment" by E. P. Walsh, United Railways Company of St. Louis, St. Louis, Mo.

Written discussion:

(a) L. S. Hoffman, general solicitor Public Service Railway, Newark, N. J.
(b) Wallace Muir, claim agent Kentucky Traction & Terminal Company, Lexington, Ky.

Tuesday, Oct. 13

9.30 a. m. to 11 a. m.

Joint session with Engineering and Transportation and Traffic Associations

Report of accident prevention board.

11 a. m. to 12.30 p. m.

Paper on "Accident Prevention."

General discussion.

Wednesday, Oct. 14

9.30 a. m. to 11 a. m.

Paper, "Claims Department Policies and Principles" by Cecil G. Rice, superintendent claims department Pittsburgh Railways Company, Pittsburgh, Pa.

(a) "The Relation of Claims Departments to the Public,"
(b) "The Psychology of Claims Adjustments,"
(c) "Efficiency in Claim Department Work,"
(d) "Office Kinks in Claim Departments."

Written discussion:

(a) W. Tichenor, claim agent Terre Haute, Indianapolis & Eastern Traction Company, Indianapolis, Ind.,
(b) J. H. Handlon, claim agent United Railroads of San Francisco, San Francisco, Cal.

11 a. m. to 12.30 p. m.

Joint meeting with Accountants' Association

Report of committee:

(a) Claims accounting.

Thursday, Oct. 15

9.30 a. m. to 12.30 p. m.

Paper on "Is Publicity Beneficial to Claims Department Work?" by C. E. Redfern, claim agent The Rhode Island Company, Providence, R. I.

Written discussion:

(a) J. J. Reynolds, claim agent Boston Elevated Railway, Boston, Mass.,
(b) J. S. Kubu, claim agent New York State Railways, Utica, N. Y.

General business.

Reports of convention committees.

Report of committee on nominations.

Election of officers.

Installation of officers.

Adjournment.

PROGRAM OF TRANSPORTATION AND TRAFFIC ASSOCIATION

Monday, Oct. 12

9.30 a. m. to 12.30 p. m.

Registration and distribution of badges at booth, entrance to Young's Million-Dollar Pier.

2.30 p. m. to 5.30 p. m.

Annual address of president.

Annual report of executive committee.

Annual report of secretary-treasurer.

Resolutions.

Appointment of convention committees.

Reports of special committees.

Reports of committees:

(a) Rules,
(b) Schedules and time-tables.

Tuesday, Oct. 13
9.30 a. m. to 11 a. m.

Joint session with Engineering and Claims Associations
Report of accident prevention board.

11 a. m. to 12.30 p. m.
Joint session with Engineering Association

Reports of committees:
(a) Block signals,
(b) Joint sub-committee on block signal rules,
(c) Transportation-engineering.

Wednesday, Oct. 14
9.30 a. m. to 12.30 p. m.

Reports of committees:
(a) Express and freight traffic,
(b) Passenger traffic,
(c) Transportation-accounting,
(d) Fares and transfers,
(e) Uniform definitions.

Paper on "Organization of a Transportation Department," by N. W. Bolen, general superintendent Public Service Railway, Newark, N. J.

Thursday, Oct. 15
9.30 a. m. to 12.30 p. m.

Reports of committees:
(a) Standards for car loading,
(b) Training of transportation employees.
General business.
Report of committee on nominations.
Election of officers.
Installation of officers.
Adjournment.

ASSOCIATION NEWS

ARRANGEMENTS FOR CONVENTION TRAINS

As announced in this column last week arrangements have now been completed by the convention transportation committee of Chicago for the special train to Atlantic City. This train will be run over the Pennsylvania Lines, leaving Chicago at 5 p. m. Saturday, Oct. 10, and arriving at Atlantic City Sunday at 4 p. m. The schedule for this special train provides for its arrival at Ft. Wayne, Ind., at 8.20 p. m., at Lima, Ohio, 9.40 p. m., at Mansfield, Ohio, 7.50 p. m. and at Pittsburgh, Pa., at 5.50 a. m. Eastern time. The train will be composed of all-steel cars, and includes an observation car, a buffet car, two diners and compartment and standard sleeping cars. Last year the special train consisted of twelve cars, and it will undoubtedly be the same this year.

Railroad fare from Chicago to Atlantic City, one way, will be $19.65, from Chicago to Atlantic City one way for a party of ten or more, $17.50, from Chicago to Atlantic City and return, $35, good returning reaching Chicago not later than Oct. 20. The return trip may be routed via Washington, provided it is so specified at the time of purchasing the ticket. Pullman fares are as follows: lower berth, $5; upper berth, $4; compartment, $14, and drawing room, $18.

Already a number of reservations have been received from the West. Those desiring to take this train may send their reservations at any time to C. Bixby, district passenger agent Pennsylvania Lines, 175 W. Jackson Boulevard, Chicago. The convention transportation committee is preparing a pamphlet which will give all the foregoing information. This pamphlet will be mailed to all member companies and manufacturers' representatives who might be interested in this train.

A special train de luxe will leave St. Louis at 12:10 p. m. Saturday, Oct. 10, stopping at Terre Haute, 4:47 p. m.; Indianapolis, 6:47 p. m.; Columbus, 12:15 a. m. Sunday; Pittsburgh, 7:05 a. m.; North Philadelphia, 3:40 p. m., arriving at Atlantic City at 5 p. m., Oct. 11. The train will contain bath-room, barber shop and buffet, clothes presser, library, compartment observation car with maid and manicure, baggage car, etc. A special round-trip fare of $40.65, available for return to St. Louis by midnight of Oct. 20, has been arranged. Sleeping-car fares are $6 for lower berth, St. Louis to Atlantic City; upper berth, $4.80; compartment, $17; drawing room, $21. Two railroad tickets are required for the exclusive use of a drawing-room and one and one-half tickets for a compartment. Meals will be a la carte excepting that a $1 table d'hote will be served as the meal out of St. Louis to "break the ice." Applications for space should be made to C. C. Curtice, 1000 Olive Street, St. Louis. The announcement regarding the train is signed by Bruce Cameron, chairman transportation committee, and the following representatives: (Railway), G. K. Jeffries, C. N. Wilcoxon, H. E. Chubbock, J. E. Gibson, A. J. Purinton, C. J. Griffith, R. D. Long, Samuel Bamburger and C. B. Wells; (Manufacturers) Scott H. Blewett, O. W. Uthoff, W. E. Norris, E. B. Meissner, E. J. Clark, H. C. Avis, A. V. Handcock, C. W. Hobson, P. A. Hendendahl, H. C. Glaze and Mervin D. Wells.

COMMITTEE ON ENGINEERING ACCOUNTING.

The final meeting of the Joint Committee on Engineering Accounting was held at association headquarters on Sept. 1 and 2. Those in attendance were J. P. Barnes, chairman, general manager Syracuse & Suburban Railroad Company; M. R. Boylan, general auditor Public Service Railway Company; M. W. Glover, secretary and auditor Mobile Light & Railroad Company; L. H. Parker, railway engineer Stone & Webster Management Association, and J. P. Ripley, J. G. White Management Corporation. The committee considered in detail the criticisms of the preliminary report which had been submitted to the members of the committee as stated in the issue of the ELECTRIC RAILWAY JOURNAL for July 25. It was found possible to harmonize conflicting ideas and the report will now be put into final form.

ACCOUNTANTS' EDUCATIONAL COURSE

The advance registration for the correspondence course which has been arranged by the committee on education of the American Electric Railway Accountants' Association has now passed the "320 mark," and there is no doubt that the remaining necessary eighty enrollments will be secured at once. The committee desires to get the course into operation at once, and F. L. Pryor, comptroller American Railways Company, chairman, urges prompt action on the part of those who still have the matter under consideration.

MANUFACTURERS' ASSOCIATION

The Manufacturers' Association office has sent out full instruction details for shipping goods for exhibits, reminding exhibitors that the exhibit committee is prepared to place the goods and assist in arranging the exhibits. Most of the exhibitors have agreed to have their exhibits complete by Saturday morning, Oct. 10, so that the convention will be virtually lengthened one day as far as the exhibit feature is concerned. The last of the series of circulars, just mailed, covers orders for electric signs.

COMMUNICATION

The Alton Plant of the East St. Louis & Suburban Company

E. W. CLARK & COMPANY MANAGEMENT CORPORATION
COLUMBUS, OHIO, Aug. 24, 1914.

To the Editors:

Some information regarding certain design features of the Alton power plant, in addition to the description which you published in the issue of the ELECTRIC RAILWAY JOURNAL for Aug. 15, may be of interest to your readers. This station appears to be rather elaborately equipped with measuring instruments for a relay station. The fact is, however, that we do not expect to operate it as a relay station longer than about the first of October. After that time we shall have our transmission line finished between Alton and East St. Louis, and then this station will carry a constant load. The amount of the load may vary from one week to another, or from one month to another, but it will not vary from hour to hour, or from day to day. Under these conditions recording instruments can make records the use of which will decrease the cost of supervision. In other words, the general superintendent of the company can follow the operation of the plant when he has such records and so keep closely in touch with the situation. As the plant is going to carry a steady load for several days at a time, he will be able to direct changes in operation from time to time as the system requires.

A low-voltage turbine-generator was purchased because, at the time we purchased this machine, the General Electric Company did not recommend 13,200-volt generation. Aside from their recommendation, however, we have always considered the auto-transformer a desirable piece of equipment, and it is quite possible that in any case of this kind we would consider its use.

A single-unit turbine-generator was purchased for this plant because we felt that in a system of the size of this one, with a peak load from 15,000 kw to 20,000 kw, units smaller than 5000 kw would not be economical. Further, this station was laid out with a definite idea that it would comprise part of a plant to contain ultimately two 5000 kw turbine units, which number will be much more desirable than a large number of small units.

Referring to the use of economizers, we have had very good success using economizers in stations of this size. The economizer with its induced-draft equipment gives, in case of an emergency station, two important resources:

First, ability to vary the draft quickly and to almost any extent; and

Second, ability to carry heavy overload on short notice, due to the considerable quantity of water in the economizer, which is nearly at steaming temperature.

In view of the facts mentioned we do not feel that the steam equipment of this station is very elaborate. The amount of money spent for recording instruments is a very small percentage of the cost of the entire station.

We have tried to put in this station meters and measuring instruments to give us the following data: Kilowatt-hours generated; pounds of coal burned; pounds of water evaporated. With these quantities before us, we work out and put into all of our reports the kilowatt-hours generated, the pounds of coal required per kilowatt-hour and the pounds of steam per kilowatt-hour. We always feel that these figures are as essential as the cost per kilowatt-hour.

I wish to point out that the most rigid economy was pursued in building this power plant and that the cost per kilowatt of station capacity is as low as any that we know of, because all available space in the station is made use of and no money was wasted for elaborate architectural designs. Although the plant is built of hard-burned brick, laid up with cement mortar, and it has a steel and concrete roof, it is a building which we feel does not require any insurance and it will last longer than the equipment. It is also designed so as to give us a great deal of light and good ventilation. So far, even though we have had an extremely hot season, we find that the station is as cool as any station could be.

Another feature which perhaps has not been noticed, is that the boilers are set single, not in batteries. This enables us to blow the boilers from both sides. From a preliminary investigation we found that this form of setting cost but slightly more than the usual battery settings and enabled us to use buck-stays for holding the furnace arches.

LOUIS R. LEE, Chief Engineer.

Public Hearing on Universal Standard Specifications for Steam Boilers

The American Society of Mechanical Engineers has announced that a public hearing is to be held on the preliminary report of the committee appointed by the society to formulate a universal standard specification for the construction and care of steam boilers. This hearing, which will be opened at 10 a. m. Tuesday, Sept. 15, in the rooms of the society in New York, has been arranged so that the report may be thoroughly discussed. A number of organizations concerned in the construction and maintenance of boilers are to be represented at the hearing, several of these having already presented written statements to the society regarding various details of the report. It is requested by the society that all those who attend the hearing send in written criticisms of the report previous to the hearing so that the progress of the deliberations may be assisted.

A number of copies of the original draft of the report are available and may be secured on application to the American Society of Mechanical Engineers. The basic idea of the work of the committee making this report has been the formulation of a standard of the highest requirements which, if adopted universally throughout the United States, will reduce the great loss of life and property due to boiler explosions and derangements which are, for the most part, preventable. It is the intention to create a standard which, it is hoped, will be ultimately adopted by the federal government and by such state governments as have no boiler regulations at present. Thus, through uniform legislation it should become possible to produce such a condition of affairs that a boiler built for any one state will be acceptable in any other.

Railway Company Offers Park to City

The municipal authorities of Joplin, Mo., have entered into negotiations with the Joplin & Pittsburg Railway with a view of taking over Schifferdecker Park, donated a year ago to the city by Charles Schifferdecker, subject to a lease which is held by the company. At the time the gift was made, the Joplin & Pittsburg Railway offered to turn the park over to the city provided it would operate it as a muncipal park. William A. Satterlee, general manager of the company, has indicated his willingness to enter negotiations, though the company has profited from the lease.

Equipment and Its Maintenance

Short Descriptions of Labor, Mechanical and Electrical
Practices in Every Department of Electric Railroading

(Contributions from the Men in the Field Are Solicited and Will be Paid for at Special Rates.)

Overcoming Field Bucking in a Motor-Generator Set

BY J. G. KOPPEL, ELECTRICAL SUPERINTENDENT OF BRIDGES, SAULT STE. MARIE, ONT.

In a certain newly-erected substation which contains one 600-hp, 2200-volt a.c., 400-kw, 600-volt d.c. motor-generator set, the d.c. end is an eight-pole commutating pole machine connected to run in parallel with a 500-kw rotary converter. Both substations supply 600-volt energy to run an interurban railway.

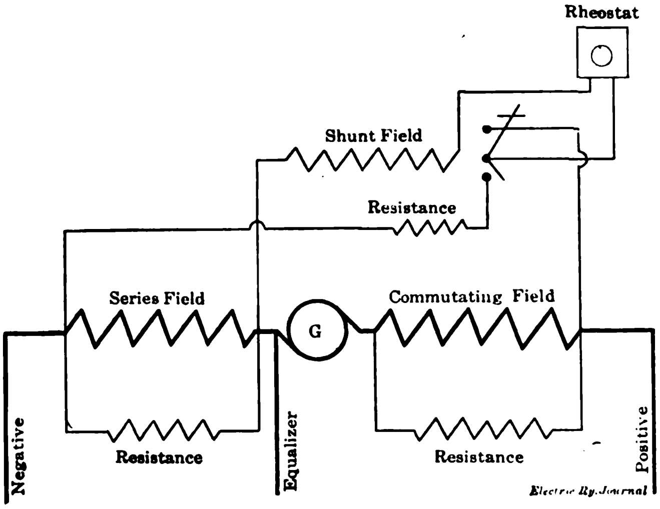


FIG. 1—WIRING DIAGRAM OF CONNECTIONS WHICH CAUSED BUCKING OF SERIES FIELD

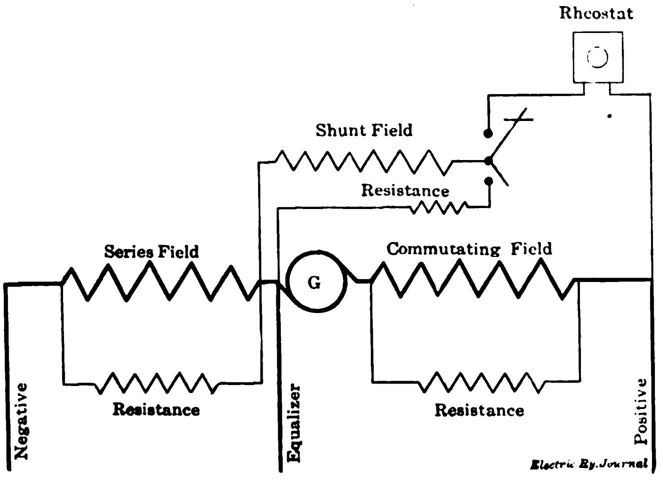

FIG. 2—WIRING DIAGRAM OF CONNECTIONS WHICH ELIMINATED BUCKING OF SERIES FIELD

In the operation of this particular motor-generator equipment, one of the most common sources of trouble was that the set in starting up always reversed the polarity so that the voltage picked up in the reverse direction; but the polarity was reversed back by the flashing of the field, and the machine was put in parallel. One day in starting up this equipment the voltage picked up in the reverse direction again, and the operator thought that the easiest way to remedy the trouble would be to reverse the leads on the voltmeter terminals. Then when the voltmeter registered 600 volts he cut in the d.c. machine to run in parallel with the other substation. On doing this a big flashover followed immediately, burning out the voltmeter and blowing out all the fuses in the lighting circuit, thus indicating that the two substations were short-circuited on themselves in series. Following this accident an expert was called to remedy the trouble.

Of the two accompanying diagrams, Fig. 1 shows the original connections of the shunt field circuit and rheostat, which indicate that when the machine was stopped by opening the shunt field circuit to cut in the field circuit discharge resistance, the shunt field circuit was in series with the series field circuit and rheostat. The investigator found that the bucking of the two fields was caused by stopping the machine in a hurry and by opening the field switch to cut in the field circuit discharge resistance before the voltage had dropped to zero. Upon this the shunt field circuit and rheostat were connected as shown in Fig. 2, and no more trouble was experienced.

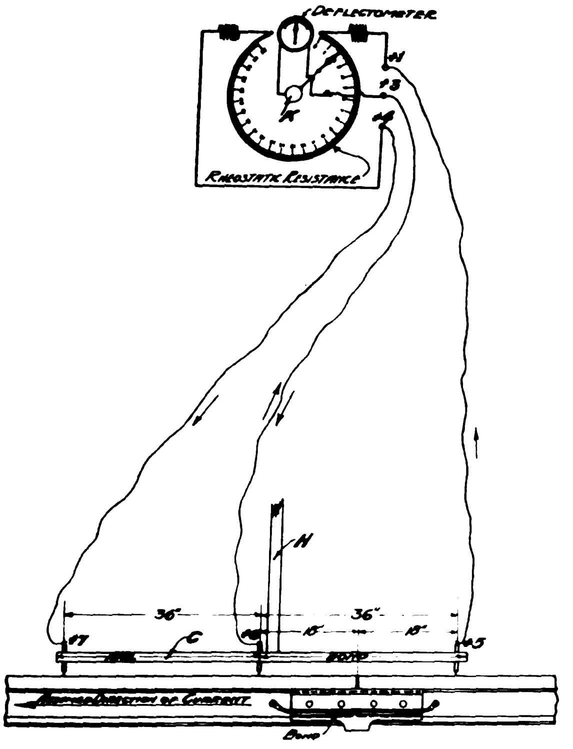
The Return Circuit—Testing the Bonds

BY HOWARD H. GEORGE, ASSISTANT ENGINEER MAINTENANCE OF WAY, PUBLIC SERVICE RAILWAY, NEWARK, N. J.

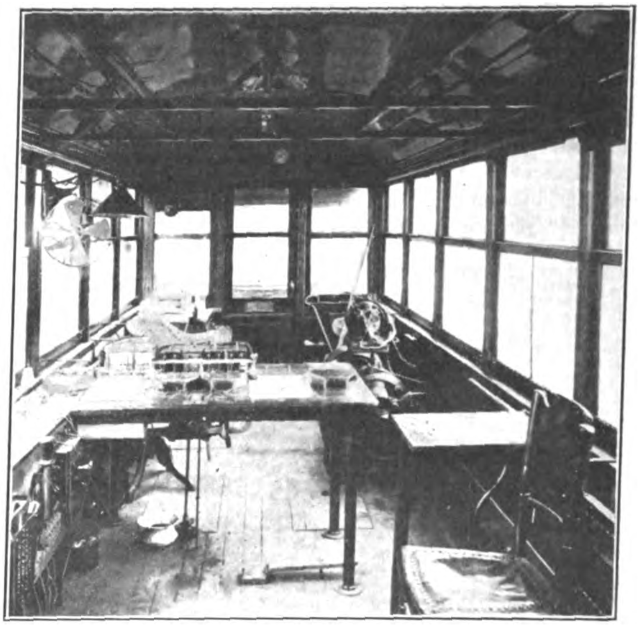
Track resistance is most easily determined by taking ammeter readings of the current flowing through a given length of track and determining the drop in potential by means of a low reading voltmeter connected to the opposite ends of the section. The calculation of the total resistance of the given length of circuit is then made according to Ohm's law, and this figure, less the rail resistance alone, will give the total joint resistance.

RETURN CIRCUITS—BOND TESTER IN USE ON PUBLIC SERVICE RAILWAY

If it is found that this is greater than the permissible allowable joint resistance, an individual test of each joint should then be made.

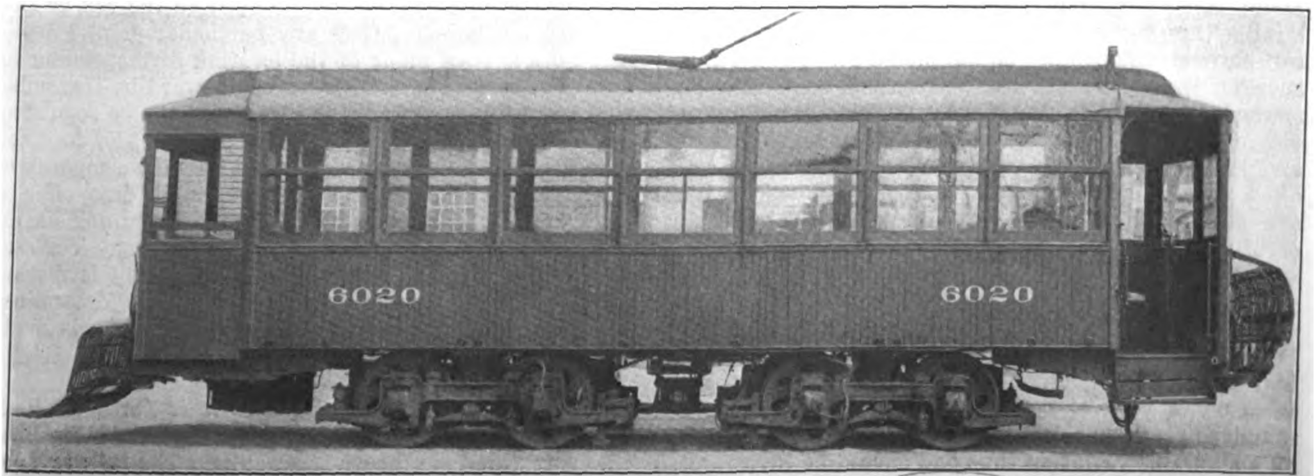


RETURN CIRCUITS—DIAGRAM SHOWING OPERATING PRINCIPLE OF BOND TESTER



RETURN CIRCUITS—GENERAL INTERIOR VIEW OF THE PUBLIC SERVICE RAILWAY BOND TEST CAR

On the Public Service Railway property such individual joint tests are made with the Roller-Smith bond tester. This is a compact, direct, reading instrument and the readings obtained are probably accurate to within a few inches of the theoretically equivalent rail length. The apparatus is shown in use in one view, its principle of operation being shown in a diagram. It consists of a T-shaped bar, *C*, upon which three contacts are mounted, and connected with the electrical mechanism as shown. The contacts are made of short pieces of hacksaw blades held in clamps. By rocking the handle *H* of the bar at right angles to the rails the blades saw through the dirt and scale on the rails and insure good contacts. The principle of its operation, like that of other bond testers, is that of the Wheatstone bridge. Assuming that the connections have been made as indicated, and that the direction of the current in the rail is the same as that shown by the arrow, there will be a certain small drop in potential between contacts Nos. 5 and 6, due to the resistance of the rail and bond. There will also be a small drop in potential between contacts Nos. 6 and 7, due to the resistance of the rail only, the distances between the two sets of contacts being the same in both cases. If the bond capacity is theoretically correct and if the bond installation has been perfectly made and has not been disturbed, the drop in the two cases should be very close to the same amount, but this is rarely the case. When the contacts have been made on the rail a portion of the current between contacts Nos. 5 and 6 is shunted through the connecting wires from contact No. 5 to terminal No. 1 of the instrument, thence over a part of the rheostatic resistance (the amount of which depends on the position of the dial), through the deflectometer to terminal No. 3 and out to the rail again through contact No. 6. This current will cause a deflection of the needle of the deflectometer. In the same way a part of the current in the rail between contacts Nos. 6 and 7 is shunted through the connecting wire from contact No. 6 to terminal No. 3 (this time in a direction oppo-

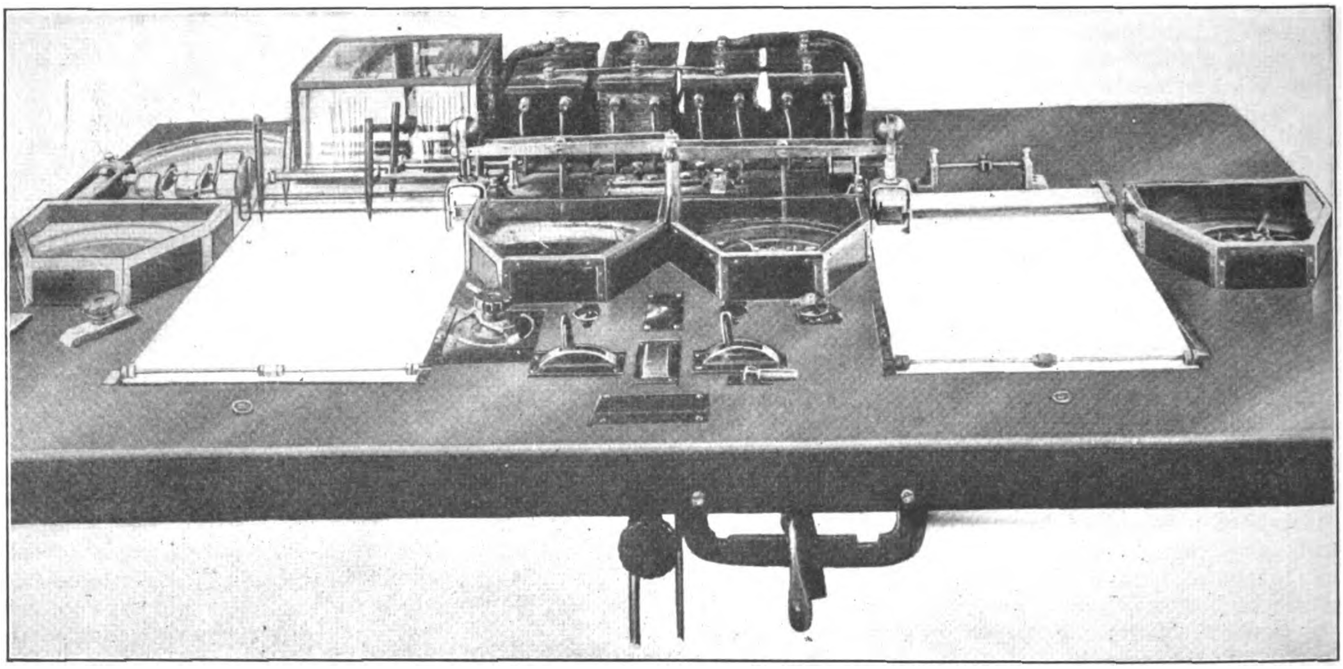


RETURN CIRCUITS—BOND TEST CAR OF PUBLIC SERVICE RAILWAY, SHOWING WIRE CONTACT BRUSHES BETWEEN THE TRUCKS

LIBRARY UNIVERSITY OF CALIFORNIA

site to that of the return circuit in the first shunt), thence through the remainder of the rheostatic resistance and the deflectometer to terminal No. 4 and back to the rail again through contact No. 7. This current also tends to deflect the needle of the deflectometer, but in a direction opposite to that in the first case. Assuming that the rheostatic resistance regulator is set at the zero point, if the resistance of the section of the rail containing the joint and bond is greater than that of the section containing the unbroken rail (which is almost invariably the case), then a greater amount of current will be shunted through the first circuit than through the second, and the result will still be a deflection of the needle in the deflectometer. If then, we can make the resistance of the two circuits the same, their effect will be to neutralize each other, and there will be no deflection of the needle. This is the function of the rheostatic resistance. By turning the handle K the resistance of the two legs of the circuit is varied. The indicator attached to the handle K moves around a scale which is so graduated as to read directly the resistance of the section containing the bond in terms of the resistance of feet of unbroken rail when the needle deflection is zero. For instance, suppose the reading of this indicator to have been 5 ft. of rail. This would have meant that the resistance of the section containing the joint would be equal to that of the 3 ft. of rail between the contact points plus 2 ft. of rail resistance for the bond itself and its terminal contacts. The method, therefore, is simply comparative, depending not only on the bond and type of contact, but on the weight and kind of rail used. However, this device offers a quick way of determining the locations of bonds which are defective. In using this method it is advisable carefully to install a few bonds under the most favorable conditions, and then take readings to establish a standard by which all other similar bonds are to be compared. Once this allowable standard resistance has been established the instrument will quickly detect all bonds with excess resistance. It is of course customary to allow a certain percentage of variation over the standard resistance, but if the resistance is greater than this allowable variation the bond should be investigated and the defects remedied. Care must be taken in using the instrument not to close a circuit over an "open joint." The instrument is very sensitive, and if too strong a current is shunted through the rheostatic resistances these are liable to be burned out. At least once, and preferably twice, a year all bonded joints should be gone over and retested to maintain a high standard.

On our own property all bonds are tested about once a year. To facilitate such an extensive scrutiny, the car shown was equipped with the Herrick bond-testing apparatus to get an autographic record of the relative resistance of every foot of rail over which the car is operated. Two wire brushes on each rail comprise the contacts. A motor in the car using line current drives a generator which sends a high amperage current through the rail between the brushes and through the testing apparatus. A special switch permits the direction of this current to be changed so as to follow that running through the rail. A part of the apparatus consists of a millivolt meter, so designed that a spark is formed as the needle is deflected. As the spark travels backward and forward it burns small holes in the roll of chart paper. The scale of the paper allows the relative resistance of each foot of rail to be read direct. A separate record for each rail is made on one roll. For later identification a numbering machine is used so that consecutive numbers can be stamped on the roll by the operator as the car passes any particular point. Separate note is then made of the location corresponding to each number. The roll is moved forward by transmission from the car wheels and its speed can be regulated at the will of the operator. This method, too, does not give direct resistance readings, but only the comparative equivalent rail resistance. However, it does offer a very rapid and dependable way of determining on an extensive scale the condition of the bonding. The sections of the track where defective bonding is discovered are then gone over and a more accurate determination of the condition of the individual joints is made with the Roller-Smith instrument.



RETURN CIRCUITS—DETAIL VIEW OF RECORDING DEVICE IN PUBLIC SERVICE BOND TEST CAR

It is reported that the Lancashire & Yorkshire Railway, Lancashire, England, intends to electrify its lines in central and southeast Lancashire. The railway is at present electrifying its lines between Manchester and Bury.

Safe Utilization of Scrap Material

BY F. J. FOOTE, MASTER MECHANIC THE OHIO ELECTRIC RAILWAY COMPANY, COLUMBUS, OHIO

There are very few subjects on which mechanical men will disagree so widely as on the subject of utilizing scrap material. This wide difference of opinion is in part due to the technical training or lack of such training on the part of the men. A man without technical training is likely to regard a piece of metal taken from the scrap pile as just as good as a new piece so long as its size and shape are suitable for the work in hand, not realizing that metal that has been in use under strain for a long time is very likely to be crystallized and the structure thereby weakened and made unfit for use where heavy strains will be again put upon it. Furthermore, much old material is inferior to new material on account of the improvements made in the art of metal working since the old material was made up, as some material found around a car shop is from fifteen to twenty years old. It is, of course, true that old steel and iron that is crystallized by overwork can be improved by working under the hammer, and it is sometimes a good proposition to work over certain old material provided the shop is fortunate enough to have a steam or power hammer. As a general rule, however, the cost of working over heavy steel and iron by hand will more than eat up the cost of new material. A great deal of old material can be used by selecting places for its use where severe strains are not put upon it, but for parts like brake rigging and parts of trucks where a failure is liable to cause an accident the use of scrap material is to be discouraged. In cases of this kind the motto "The Best Is None Too Good" is a very good one to keep constantly in mind. Another objection to the use of scrap material is that it rarely fits the job in hand and some alteration must generally be made in it; these alterations, if slight, make its use profitable, but in many cases the alterations and the work required to put the material in shape for use will more than pay for new material.

This brings up also the question of "home-made" tools and devices. Some mechanical men get the idea that because they are ingenious enough to devise and construct tools in their own shops, it is good policy to do so rather than to purchase them from reliable dealers. In the case of special tools that cannot be found on the market at a reasonable price, or in case the management absolutely refuses to purchase much needed tools, the practice of making tools is justified. Generally speaking, however, the home-made tools are not up to the standard in quality or capacity of the commercial tools, and often the actual cost in labor and material is greater than the price of the tools. The writer remembers one case in particular where a certain tool was made in the home shop for the track department at the expense of much of the blacksmith's and machinist's time when they should have been kept on more important work.

Some scrap material was used, yet the actual cost was without doubt as much as the tool could have been purchased for. Owing to the fact that this tool was not designed, but simply "built," it proved entirely too light for the work it was to be used on and it is now in the scrap pile to stay, a total loss.

But to return to the subject of scrap, it is certainly every master mechanic's duty to make frequent visits to the scrap pile to see if his men are throwing away parts that could have been used safely for a greater length of time, and also to see if any material is scrapped that should have been laid by for other uses at some future time. Someone has said that he can tell what kind of a man the shop foreman is by looking at his scrap pile. The writer is willing to agree to this, with some restrictions; but the point to be emphasized is that errors are made in utilizing too much scrap material, just as surely as in not using enough of it.

A Home-Made Crossing

BY CARL H. FULLER, ENGINEER MAINTENANCE OF WAY MACON (GA.) RAILWAY & LIGHT COMPANY

At the intersection of our Third Avenue single-track line with our Mulberry Street double-track line, we had an old crossing of irregular shape, as shown in Fig. 1 of the accompanying drawing. This had become badly shattered, all intersections being broken and the wing joints battered down. Owing to heavy renewals elsewhere this crossing was neglected until its rapid disintegration necessitated immediate renewal. As the mills at that time were unable to promise delivery under ninety days and as the necessity for a new crossing was urgent, we decided to manufacture a temporary one to care for the emergency. A sketch was prepared, as per Fig. 2, with all the wing rails of equal length and long enough to eliminate the bad joints. From this sketch a crossing was made and installed on Nov. 18, 1913. Both the shop and field work was done with great care, so that although the crossing has been in service nine months under 900 to 1000 car movements a day, it appears to be as good as when put in. At the same time a saving of $300 was effected over the shop-built crossing.

The cost of manufacture was as follows:

Bolts and miscellaneous fittings	$12.56
Eight cast-iron angle-bars and pattern	41.70
Twenty-four forged angle-bars, material only	36.00
Labor fabricating crossing	64.15
Total	$154.41
Quotation for shop-built crossing	452.00
Saving over price of manufactured crossing	$297.59

No rail is included in the foregoing costs, as scrap ends from new 6-in. 72-lb. rail, left over from 60-ft. rails used on paving jobs, were utilized. The double track rails, marked *A* in Fig. 2, run clear through the crossing without any break except the slot in the ball for the passage of the wheel flange. All rail was cut to length on a power hack saw, and all drilling for bolts and bonds was done with a Duntley electric track drill. The intersecting joints are made up of three forged angle-bars ground to a tight fit and one cast-steel angle-bar, Figs. 3 and 4, the latter cast at a local foundry. The cast angles were made for a bevel fit with two slight ridges on the side next to the web of the rail to give an even bearing.

The cost of installing the crossing was as follows:

Bonds and bonding material	$30.24
Paving material, cement, brick, etc	23.00
Labor including repaving	40.40
Total	$93.64

The removal of paving began late in the afternoon, and when the last car went to the carhouse at midnight the old crossing was pulled out bodily, after which we had four hours to cut the old running rails with hack saws and put in the new crossing. Rails *A* were placed first and exterior joints bonded and bolted, after which rails *B*, *C*, *D*, *C*, *B* were placed in that order and the angle intersections bolted up, this work being finished in time for the first car leaving the carhouse at 4.50 a. m. (The last car turns in at 11.40 p. m.) Bonding of the internal joints followed, one 9-in. concealed bond being used in each external joint and three 36-in.

stranded bonds for each intersecting joint. Repaving with concrete and brick followed the bonding. The slightly dampened concrete was thoroughly tamped under the rails and around the ties, the brick being laid on a 1-in. sand cushion and the joints filled with thin grout. The slight roughness of the paving surface is due to the fact that teams were driven over the work before it was finished, but otherwise it is firm and solid. Four working days and one night were required from the time of cutting the first rail in the shop to the final grouting of pavement.

Only one criticism appears to have been made about this crossing, aside from the fact that it is much lighter than shop-built crossings, and this refers to the effect of the nosing of car wheels in the rail slots. This objection could easily be avoided by using three cast angle-bars and one forged angle-bar in place of the one cast angle used at each intersection, as the groove in these cast angles is slightly flared to take the wheels. This change would increase the cost slightly, but not as much as might appear, since the price, $41.70 for the eight castings, includes the cost of the pattern. This type of construction also has the advantage of permitting the renewal of any single part without much trouble, owing to the all-bolted joints. The cast angle-bars appear of ample section to take care of the wheel hammer, and the grooves were made high enough to carry the wheel flange over the rail slots.

The Pacific Motor Coach Company has installed a service of double-deck motor buses between Los Angeles and Venice—a suburban resort near Los Angeles. Eleven buses have been received, and it is stated that ninety-four more have been ordered from the Kelly-Springfield Company. Each bus has seats for fifty-four passengers, and the fare for the round trip is 50 cents.

MACON HOME-MADE CROSSING AS INSTALLED AT THE INTERSECTION OF THIRD AVENUE AND MULBERRY STREET

Concrete Trolley and Lighting Poles in San Francisco

San Francisco has adopted concrete trolley wire poles for the municipal railway system to be built under the $3,500,000 bond issue approved last year. For the most part these poles will be non-ornamental concrete shafts, equipped with metal cross-arms where feeders are carried, and on other lines provided only with eyebolts for wire supports. On Van Ness Avenue, however, it was desired to use an ornamental pole suitable for carrying the street lamps as well as the trolley wire, and a more elaborate design was developed. The concrete shafts for these ornamental poles have already

STANDARD AND ORNAMENTAL TROLLEY AND LIGHTING POLES FOR SAN FRANCISCO been cast and will be erected on completion of the track-laying, which is now under way.

As shown in the accompanying illustration, these poles have bases, lamp brackets and caps of metal, and each will carry two 200 cp tungsten lamps. Van Ness Avenue is 81 ft. wide between curbs, immediately back of which the poles will be set. The sidewalks are 22 ft. wide, and the poles will be placed every 92 ft. The contract has been awarded for about 2 miles of double track served by poles of this ornamental type.

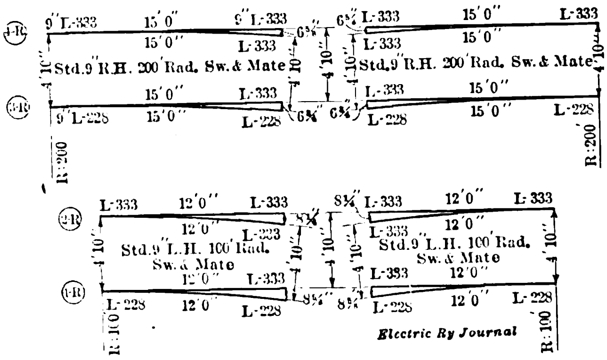
The contract for supplying and erecting the ornamental poles was awarded on a basis of $128.22 for the standard poles and $132.50 for the strain poles. The non-ornamental poles in place, with cross-arms, are to cost $51.15 for the standard poles and $55.70 for the strain poles. Riser poles with two conduits are to cost $65.67.

The ornamental design was developed by the city's consulting board of architects, and the engineering details of these poles were worked out by R. J. Wood of the engineering department, who also designed the other concrete poles in the municipal railway system. The entire work is under the supervision of M. M. O'Shaughnessy, city engineer of San Francisco.

St. Louis Track Special Work Standards

The track department of the United Railways of St. Louis has not only adopted up-to-date track-work standards but is adhering to them in new construction. In August, 1911, the standards described in this article were adopted, and since that time approximately 1800 of the standard pieces have been purchased.

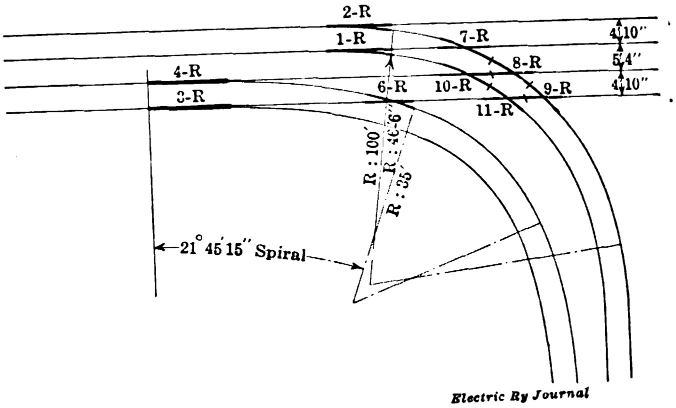
Standard special-work pieces include switches, mates and frogs, both right and left hand, totalling twenty-five in all. All of these standard pieces are purchased in several rail sections and weights to meet varying traffic conditions. These rail sections include a 9-in. Lorain section 440, Trilby rail, weighing 132 lb. to the yard, and 9-in. Lorain 333, weighing 112 lb. to the yard. In the 9-in. girder-guard rail the sections used are the Lorain 441, weighing 150 lb. to the yard, and the Lorain 228, weighing 117 lb. to the yard. Under light traffic conditions a 6-in. Lorain 225, weighing 78 lb. per yard, is used with a 6-in. Lorain section 257, weighing 97 lb. per yard as a guard rail. Most special work, however, is purchased in the Lorain section 333, with section 228 guard rail.



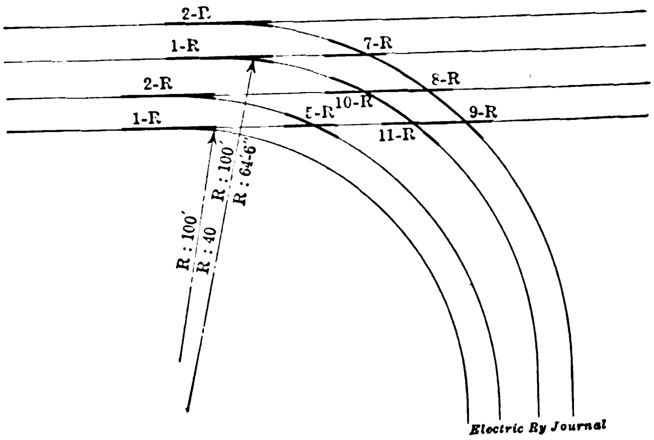
SPECIAL WORK STANDARDS—SWITCHES AND MATES,

Switch and mate standards include 9-in. right and left hand, 100 and 200-ft. center radius pieces. The over-all dimensions of these four combinations are shown in the accompanying illustrations. They conform to the recommended designs adopted by the A. E. R. E. A. in 1911. The 200-ft. radius switch and mate, shown as pieces Nos. 3 and 4, are used in combination with frog piece No. 6, where it is possible to get car clearance. Pieces Nos. 1 and 2 are considered as the standard switch and mate and are generally used with frog No. 5 in most of the single-track branch-offs. When frog No. 5 cannot be used on account of obstructions or because of other clearance difficulties, frog No. 7 with a slightly flatter angle usually takes its place.

Pieces Nos. 7, 8, 9, 10 and 11 are used in conjunction with pieces Nos. 1 and 2 in right-hand trailing and left-hand facing branch-off of double track. On occasions pieces Nos. 8, 9, 10 and 11 are used to make up a curve crossing over straight track. The over-all dimensions of these five frogs are shown in one of the accompanying illustrations. It will be noted that the lengths of arms are designed so that short-rail sections will be unnecessary to make up the complete layout with the standard track centers of 10 ft. 2 in. As noted before, frog No. 7 is sometimes used in the 100-ft. radius standard turnout in order to obtain car clearance. Accordingly it will be seen that this curved crossing begins with a 100-ft. radius turnout and ends with a 46-ft. 6-in. inside radius curve. It also must be noted that the St. Louis standard gage is 4 ft. 10 in., consequently these dimensions would not apply to standard gage track. This layout also is made up with right or left-hand pieces.



SPECIAL WORK STANDARDS—RIGHT-HAND BRANCH-OFF, CARS CLEAR



SPECIAL WORK STANDARDS—RIGHT-HAND BRANCH-OFF, CARS DO NOT CLEAR

On the United Railways property, as probably would be the case with other street railways, piece No. 12, or one-half of a right-angle crossing, has been purchased more than any other. While it may be contended that a right-angle crossing will not fit every street intersection, most of them are within a few minutes of 90 deg. Consequently the United Railways ignore any variation of ten minutes or less without any apparent effect on the track alignment. In the adoption of the over-all dimensions, the exterior arms were made of the correct lengths to eliminate short-rail sections between tracks, and the two interior arms were made equal to one-half the track gage in length.

Cross-overs also have been standardized, and frogs No. 13 and 13A with a 13-deg. exterior angle are used in these layouts. These frogs also are used in long-radius branch-offs at streets intersecting at acute angles. As will be noted, these frogs are tangent throughout their length, thus requiring a curve in the lead and a curve beyond the frog. As will also be noted, at one end of piece No. 13 the rails are back to back and at the other lip to lip. In 13A, however, both ends are lip to back, which is required when the frogs are in the two rails of the same track. This is shown in the diagram of a standard 13-deg. branch-off.

SPECIAL WORK STANDARDS—RIGHT-HAND CURVED CROSSING

As the railway company has strictly adhered to these standards in all special work layouts, it was possible for the manufacturers to carry patterns in stock, and in some instances where the pieces were bought frequently the manufacturer carried a few of them in stock. In either case, however, deliveries could be made on short notice, and the company did not hesitate to order an excess of its requirements, because none of the pieces were special. All of these layouts are being purchased in solid manganese steel, but the over-all dimensions and the standards adopted could just as readily be furnished in hard center or ordinary built-up work.

To give an idea of the number of pieces of each kind purchased since the adoption of these standards, the following list is given: Pieces 3 and 4R, 27; pieces 3 and 4L, 29; pieces 1 and 2R, 364; pieces 1 and 2L, 382; piece 5R, 44; piece 5L, 44; piece 6R, 8; piece 6L, 10; pieces 13 and 13A, 77; piece 12, 390; piece 7R, 23; piece 10R, 17; piece 8R, 16; piece 11R, 16; piece 9R, 14; piece 7L, 22; piece 8L, 16; piece 10L, 16; piece 11L, 18, and piece 9L, 15.

SPECIAL WORK STANDARDS—RIGHT-HAND AND LEFT-HAND 13-DEG. CROSSOVERS AND 90-DEG. CROSSING

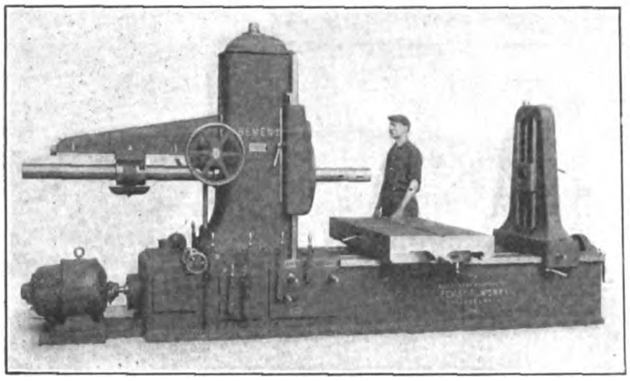
According to the sixth annual report of the Railroad Commission of Nevada for the year ended Dec. 31, 1913, the total capital stock of the Reno Traction Company was $1,000,000 and of the Nevada Interurban Railway $44,695. The funded debt of the Reno Traction Company was $136,000. The total cost of plant to date of the Reno Traction Company was $1,323,474 and of the Nevada Interurban Railway $86,686. The income account of the Reno Traction Company showed the following items: Gross earnings from operation, $57,878; operating expenses, $42,327; taxes, $2,461; gross corporate income, $13,089; net corporate income, $8,714. The gross earnings from operation of the Nevada Interurban Railway were $9,426; operating expenses, $9,535, giving a net corporate deficit of $109.

Use of Binoculars

Referring to the article "Detecting Line Troubles with Binoculars," in the ELECTRIC RAILWAY JOURNAL for May 30, 1914, G. W. Palmer, Jr., electrical engineer Bay State Street Railway, Boston, Mass., states that the Bay State company has, for the last five years, inspected its 65 miles of transmission line with binoculars monthly, in addition to the daily patrol of the entire line. Mr. Palmer adds that the use of the field glasses has revealed defects which otherwise would not be apparent and which, if not attended to, would have resulted in line trouble.

Duplex Control, Horizontal Borer, Driller and Miller

Realizing the importance of duplex control on boring machines, the Niles-Bement-Pond Company is now manufacturing the improved horizontal borer, driller and miller illustrated herewith. This machine is of the elevating spindle type, but is symmetrical throughout with respect to the spindle axis, permitting the operator to stand on either side and have all the controlling levers within convenient reach. It is adapted for work requiring great accuracy and at the same time is designed for heavy boring. Service and durability are prominent features, the entire design being free from delicate parts.



HORIZONTAL BORER, DRILLER AND MILLER WITH DUPLEX CONTROL

Perhaps the most striking feature of the design is the location of the spindle saddle within the post. This makes possible the symmetrical construction about the spindle axis which has been carried throughout the design of spindle post, bed, tables and control—an arrangement very essential on a large part of boring work. This design also affords most rigid support for the spindle. The thrust is taken on two *V* tracks, one on either side of spindle, eliminating entirely the distorting strains which are inevitable in machines where the spindles and saddles are on the front side of the post.

The standard table is 33 in. wide x 60 in. long, and the travel across the machine is 48 in. The spindle diameter is 4½ in.; diameter of the taper hole at the large end, 3 in.; the traverse is 60 in. in two shifts of 30 in. each, and the speeds are 5 to 150 r.p.m. Six feeds are provided for each spindle speed. The amount or advance of the feed selected is always per turn of spindle and is independent of any change made in the spindle speed. As to capacity, the maximum distance from the center of the spindle to the standard work table is 30 in., and the maximum distance between the face plate and the outboard bearing 7 ft.

For d.c. drive a 10 hp variable speed motor of 3 to 1 range is recommended. If alternating current only is available, a four-speed motor of 600, 900, 1200 and 1800 r.p.m. is recommended. Cone and counter, or single pulley through speed box, drives are also available.

Among the extra attachments of this machine are the following: a plain circular table 38 in. in diameter, graduated in degrees; a circular table 38 in. in diameter, having power rotary feeds; an auxiliary work support on bed for long pieces; boring bars of any diameter; bell chuck for driving boring bars not having taper shanks; and facing head which may be attached to the face plate or boring bar with capacity to face up to 25 in. diameter.

Four Hundred and Fifty-six Additional Motors for Chicago

Four months ago the Chicago City Railway, now one of the Chicago Surface Lines, Chicago, Ill., started to place in service 100 new cars equipped with 200 GE-242 motors, or 100 double motor equipments, air-brake equipments and accessories. All of these cars have been in service for some time, and the performance of the motors and equipments has been so satisfactory that the Chicago Surface Lines have recently placed another order with the General Electric Company for 456 motors of the same type, or 228 double motor equipments, air-brake equipments and accessories to be installed on new, double-truck, semi-convertible cars being built by The J. G. Brill Company.

The details of the construction of the GE-242-A motor were described very fully in the June 20 issue. GE-242 Form B motors will be installed on the last lot of new cars. Under the A. I. E. E. standard, the GE-242 motor has an hourly rating of 65 hp at 600 volts and 55 hp at 500 volts, but has a greatly increased service capacity when compared with motors of the closed type having the same hourly rating, on account of the positive circulation of air that is maintained throughout the motor by the system of self-ventilation. The motors are of the box-frame type, fully ventilated, and are provided with commutating poles and arranged for tap-field operation. They will be fitted with seventy-one-tooth, solid, armorized steel gears and fifteen-tooth pinions having a working face of 5 in.

The controllers are of the K-51-A platform type. Straight air-brake equipments will be used with CP-27-B compressors. The compressor has a piston displacement of 15 cu. ft. of free air per minute when operating at 600 volts against a reservoir pressure of 90 lb. per square inch.

Representative runs, calculated on a basis of actual operation, will indicate the service conditions on the surface lines in Chicago. A representative average run may be taken at a speed of 11.76 m.p.h., not including the duration of stops, with 6.77 effective stops per mile. The average duration of stops is 6.04 seconds. The average load on a run of this kind is thirty-two passengers. A representative maximum average run may be taken at an 11.9 m.p.h. schedule, not including the duration of stops, with 8.1 effective stops per mile. The average duration of stops is 8.5 seconds and the average load for this run is thirty-two passengers. A representative maximum run may be taken at a 12.3 m.p.h. schedule, not including the duration of stops, with 8.5 effective stops per mile. The average duration of stops is 8.4 seconds and the average passenger load is forty-two for the maximum run.

The car completely equipped will weigh about 40,000 lb. It has a total seating capacity for fifty-four passengers and is mounted on 32-in. wheels.

LONDON LETTER

Motor Bus Service, the Midland Electrification and London's Electricity Supply Discussed

(From Our Regular Correspondent)

The manager of the Southampton Corporation Tramways has reported on the question of running motor buses in conjunction with the tramways. Taking the running expenses in six towns in various parts of the country where motor buses are being used, the manager states that they vary considerably, but with modern double-decked vehicles would appear to be about 10d. per bus-mile. For the purpose of comparing this figure with the cost of running the Corporation trams, the manager has taken the average costs per car-mile for the last three years, including traffic and general expenses, repairs and maintenance, cost of power, interest on capital, repayment of capital, income tax, and claims paid out of the third party insurance fund. The figure he gives is 9.42d. per car-mile. He has added the average cost of all renewals for the last ten years, 0.57d. per car-mile, thus making the total cost of running the cars, including everything, 9.99d. According to the report it would cost exactly the same, 10d. a mile, to run a double-decked petrol bus, with a seating capacity of thirty-four, as it does to run a tramcar, with a seating capacity of, say, fifty-six. Assuming that each vehicle annually ran an average of 30,000 miles, the cost per seat per annum for running the tramcar would be £22, and for the motor bus £36, an increase for the latter of 63 per cent. The difficulties of dealing with rush traffic on a wet day would necessitate a large fleet of spare buses, which would be used for two or three hours daily. If buses were substituted for trams in Southampton, many more miles would have to be run to earn the same revenue, with a consequent reduction, if not an entire loss, of profits. On these grounds the manager bases his opinion that the tramcar is still the most suitable vehicle for transporting passengers in a provincial town like Southampton, and finds that there are no substantial grounds for assuming that it will shortly be ousted from its place by the motor bus. After considering the report, the tramways committee has resolved to recommend the purchase of three buses, at a cost of about £2,600.

With regard to the Manchester Corporation bill, the tramways committee has obtained powers to carry out a number of extensions. It has permission to run omnibuses as stage carriages for the convenience of passengers, with or without passenger luggage, and small parcels not exceeding 56 lb. in weight. The committee has authority to run these omnibuses in the city, and outside the city along roads in which tram lines are laid and which are rented or leased by the Manchester Corporation, on condition that the Corporation contribute to the local authority concerned at the rate of three-eighths of a penny a car-mile for each omnibus, this contribution to be applied towards the upkeep of the roads. As to the slopes connected with railway bridges, the obligation to repair is placed by statute on the owning companies. Under the new bill, however, the companies will be entitled to receive three-eighths of a penny per car mile, the same as the local authorities receive, for the use of such slopes. Under the bill the Corporation has power to acquire land and construct a new generating station in Trafford Park, and to connect such station with the Manchester area of supply.

The House of Lords Committee has passed the Middlesex County Council bill. This measure contains a clause whereby the omnibus companies will have to pay three-eighths of a penny per mile run towards the maintenance of roads. A committee of the House of Commons had already approved this clause. The companies must allow the County Council access to their books. The Derbyshire County Council has also made a charge of three-eighths of a penny per car-mile on the Sheffield Corporation omnibuses, and the same committee which passed the Middlesex bill subsequently dealt with the Walsall bill. The Corporation of Walsall has agreed to the principle of a three-eighths of a penny per car-mile road tax upon its omnibuses.

The new electric omnibus service has been established between Stanhope Road, South Shields and Green Lane West. The service is intended to link up the Green Lane district with the South Shields Corporation Tramways. The electric buses which have been acquired by the South Shields Corporation are the first of their kind to be used in England. They were supplied by the Edison Accumulators, Ltd., and were placed in experimental service in London over 13 miles of busy streets in the West End.

The committee of the House of Commons which has been considering the Kelvin Bridge new road and tramway proposal in the Glasgow Corporation bill has passed that proposal without alteration, and has also passed the remainder of the bill. The attempt which had been made to come to an agreement with the Queen Margaret College authorities was not successful, so that the committee heard the rest of the evidence in opposition to the bill by that body. It rendered its decision after deliberating five minutes.

The Midland Railway's electrification scheme is far more ambitious than is generally realized. There are really two projects, one for the conversion of the London, Tilbury & Southend Railway, now part of the Midland, and the other for the electrification of the company's original suburban lines in the Metropolitan area. Each of these is an imposing scheme in itself, and there is in addition the proposal for a new line between Bromley and Stepney. Although this is to be only 1½ miles in length, it is of the utmost importance in the working out of the electrification scheme. The cost for this section is estimated at about £630,000. In addition, the present lines from Barking to Upminster will be doubled for a distance of 7¾ miles, so that there will eventually be a four-track road from Fenchurch Street to Upminster. The Fenchurch Street terminus will also have to be enlarged, but it is considered useless to proceed with this or with the electrification until the work previously described has been carried out.

The Cardiff Tramways committee has decided to hand over another £4,800 from its profits for the relief of the rates. A similar contribution was voted for the half year ending September last.

The Bristol branch of the Electrical Trades Union has passed a resolution viewing with pleasure the decision of the citizens of Bristol to purchase the trams, and strongly urging the City Council, in order to obtain the fullest advantage of this vote, to conclude the purchase and arrange to work the undertaking at the earliest opportunity.

In its battle with motor-bus competition, the London County Council is considering the construction of a series of tramway extensions and the linking of existing lines at several points. If all the proposals are adopted the cost, as estimated by the finance committee, will exceed £1,250,000. Many of the proposals, however, are opposed by the borough councils on various grounds, and it is doubtful if the Council will eventually secure Parliamentary power for all its schemes, which are being considered in conjunction with the report of M. Mariage, the French tramway expert. The Council also proposes to run more trail cars and to issue more return tickets. Great interest has been aroused by the announcement that a proposal for "penny-all-the-way" fares is to be brought before the Council. Traffic experts say that the adoption of such a principle would revolutionize the tramway system, and many believe it would enable the tram to compete successfully with the motor bus.

The London County Council has announced its plan of dealing with the problem of London electricity. The proposal is not to have a municipal scheme, but rather to arrange for co-operation with all existing undertakings, though ultimately all the concerns will become the property of the municipality. There will be no scrapping of plant, but the Council recognizes that electricity will have to be generated in bulk on a site down the Thames. No compulsory purchase of existing concerns is suggested, but it is proposed that these undertakings should receive the option of at once handing over their organizations upon agreed terms to the new authority. These proposals will require Parliamentary sanction and are put forward by the London County Council because it is recognized that Parliament will not sanction either a municipal or a private company scheme.

News of Electric Railways

INDIANAPOLIS ARBITRATION FINDINGS

Twelve Questions Affecting Employees and Company Passed Upon—Company's Summary of Decision

The board of arbitration selected to settle disputes between the Indianapolis Traction & Terminal Company, Indianapolis, Ind., and its union employees, has decided twelve questions at issue between the two parties, some of which have been before the board for adjudication for several months. The paramount question, that relating to the individual contracts which the company and its non-union men have been signing, was decided by the board in favor of the union men in all points wherein the individual contracts conflicted with the former award of the Public Service Commission, sitting as a board of arbitration in the strike arbitration last fall. The decision, however, expressly stipulated that the individual contracts would become effective Nov. 8, 1916, the date of the expiration of the "Governor's agreement, which settled the strike last fall, or at an earlier date if all employees execute it."

Among other findings of the arbitration board were the following: That the union officials or agents have not the right to solicit membership or collect dues from members of the union on the premises of the company; that the eight-hour rest provision of the original award shall continue unabridged in any particular; that the company shall have the right to employ extra men for services on Sundays and holidays, paying them at the regular rate an hour fixed by the award of the commission, this pay not to be subject to the $45 monthly minimum provided for the men on the "extra" list of the company; the board orders and directs the company "not to encourage or authorize any of its employees to carry concealed, dangerous and deadly weapons, under any circumstances, while on duty," that the company should not coerce any of its employees into entering into the insurance scheme, which the union employees allege the company now is operating, although "the prudence of the employee who seeks, by means of some reliable insurance plan, to protect himself and family against the contingency of accident and sickness cannot be gainsaid or questioned."

The following summary of the decision was issued by the company:

"These words from the decision fully explain the status of our service contract: 'On Nov. 8, 1916, this contract will determine the rights of all who have then executed it. It will become effective at an earlier date if all employees execute it. It is now effective in every particular in which it does not conflict with the original award.'

"The decision of the board of arbitration leaves our service contract in full force and effect except that wherever it now appears to conflict with the award of February, 1914, it must be construed in harmony with that award.

"The effort of the committee to embarrass the company in the employment of extra men on Sunday by enforcing the payment of a $45 per month minimum monthly wage for four days' work, failed. Under the present and prospective labor conditions, the company hopes to have no difficulty in getting extra men to run the cars on Sunday. The chief effect of the award is to disqualify our regular employees from taking their regular Sunday runs on one Sunday in each month, and also whenever eight hours do not intervene between the end of the Sunday run and the beginning of the Monday run. This frequently happens for the reason that the service demanded by the public on Sunday is chiefly in the afternoon and evening, while on other days in the week the heavy service is required in the early morning. We will continue under these conditions to have work for about 200 extra men each Sunday.

"The decision does, however, leave a clear and plain opportunity, resting with the men themselves, to secure the right to do this Sunday work by continuing to sign the service contract, until by numbers they make it clear that it is their desire to run the cars on Sunday, rather than to permit the extra men to do so. As nearly 70 per cent of the regular motormen and conductors have already signed the service contract and others are doing so daily, it seems probable that the employees of the company will not long leave the Sunday runs to outsiders.

"The compensation which our motormen and conductors could earn by operating their cars on Sunday, and of which they are deprived by this decision, is a matter of considerable importance to many of them."

NEW YORK COMMISSION EXHIBIT

Maps, Statistics and Miniature Block Signal System Among Things on View at State Fair

At the State Fair in Syracuse, which opened on Aug. 31, the Public Service Commission for the First District of New York has a large and important exhibit, which occupies about 1600 sq. ft. in the center of the building devoted to liberal arts and manufactures. It shows the general character of the work which the commission has been doing, especially in the field of providing additional rapid transit for New York City. Maps and statistics of the dual system show the scope and extent of the new lines, the progress of the work, the amount of money already expended and the number of contracts already under way. The large models, made carefully to scale, give an excellent idea of the appearance of two of the principal stations of the new underground lines when completed. These are the so-called diagonal station in Forty-second Street in front of the Grand Central Terminal, which will connect the new Lexington Avenue subway with the existing subway, and the Times Square station at the intersection of Forty-second Street and Broadway and Seventh Avenue, where the new subway in Seventh Avenue will join the existing subway running north in Broadway. Close by is the Forty-second Street station of the new Broadway subway, and the model shows how the two stations will be connected by underground passageways.

The commission also shows a model of the latest track construction to be used in the new subways. This model is made of sections of steel rails laid on ties and ballasted with concrete, all of the materials being typical of those which will be used in actual construction. A part of the commission's exhibit, loaned by the Interborough Rapid Transit Company, shows a miniature section of the existing subway equipped with an exact duplicate of the block signal system used in actual operation. Miniature trains are operated back and forth and the workings of the signal system which guards the safety of the millions of passengers carried every year in the subway are demonstrated. Near by is also shown a model of the Interborough Company's main power station, which generates the electric current used for the operation of the subway.

An interesting part of the exhibit is a display by the materials inspection division of the commission's engineering department. Here are shown samples of all the materials used in the construction of subway and elevated railroads and the careful tests to which they are submitted by the commission's engineers before being accepted for use. They include samples of sand and gravel which enter into the composition of concrete; samples of cement; sections of steel rails, girders and beams and fragments of timber from which the ties are made. The samples are selected to show the defects which cause the rejection of materials as well as the perfect specimens which are examined and pass all tests.

A large assortment of charts and maps illustrate various phases of the commission's work in building subways, regulating transportation companies, gas and electric companies, and eliminating grade crossings on steam railroads. A collection of photographs shows some of the fender tests held by the commission, which resulted in a series of orders requiring all street surface railroads operating in Greater New York to equip their cars with effective life-saving fenders and wheel guards. Many interesting views of actual construction work on the new subway and elevated lines are shown on an illuminated screen by means of an electrically operated stereo-motorgraph which automatically projects and changes the views. The exhibit at Syracuse will form a part of a larger exhibit to be made by the commission in the city of New York Building at the Panama-Pacific Exposition in San Francisco next year.

UNITED RAILROADS HEARING

Final Action by California Commission in Inquiry Into Finances Not Likely for Several Weeks

The investigation into the finances of the United Railroads of San Francisco which is being conducted by the California Railroad Commission was continued on Aug. 28. The first hearing was reported in the July 25 issue of this paper and the second hearing, that on Aug. 24, was reported in the last issue. At the hearing on Aug. 24, after the commission had considered the question of the Calhoun note, as described last week, it called for an explanation of the methods of accounting employed by the United Railroads, with which the commission has differed for some time. John F. Forbes, an expert accountant representing the firm of Haskins & Sells, who was then put on the stand, declared that during the period of Mr. Calhoun's administration he had audited the United Railroads' books and that they had been kept in accordance with the requirements of the American Electric Railway Accountants' Association and the Interstate Commerce Commission.

In answer to the statement previously made by L. R. Reynolds, expert for the commission, who could not account for $3,906,000 that he thought should appear in the company's books, Mr. Forbes produced figures to show that the United Railroads has a real surplus of $1,018,632. He also defended the system of bookkeeping used and claimed that the company had a right to declare dividends on the first preferred stock of $5,000,000.

At the hearing on Aug. 28 the witnesses included Messrs. Black and Legare and two certified accountants. The keynote of Mr. Black's testimony was that under the provisions of the city charter since the 1912 amendment went into effect, it was absolutely impossible for the United Railroads to undertake new construction and that the company's activities would be confined to improving the present system and service. Evidence was introduced to show the present good condition of track work, paving and overhead construction. The rapid rehabilitation after the fire was explained with charts and cost figures. It was pointed out that the present average monthly maintenance cost, about $38,000, was far less than formerly because of the introduction of more efficient methods. Electric welding was cited as one of the many savings by which this had been effected, as many of the damaged parts which would have been scrapped in former years were now made serviceable again by this method.

The company finished submitting its evidence at this hearing and the hearing was declared closed. Attorney E. J. McCutcheon, who said that he represented the interests of certain bondholders in the matter under discussion, requested permission to file a brief. This was granted, provided the brief should be filed within ten days. The commission then said that it would grant to the attorney of the company another ten days to file a reply to this brief if such action was desirable. As the commission will then have to take the matter under advisement, no final decision is likely to result for four to five weeks.

TRAMWAY MEN AT WAR

About 5000 Employees on Eleven English Systems Called Out—Reinstatement After War

Many of the English tramway systems have been particularly hard hit by the war. Not only are losses in earnings reported, but there is depletion of the operating forces by the enlistment of officers and trainmen for service at the front. Both the municipal tramways and the privately owned properties have shown a very liberal spirit toward their men. The London United Tramways, for instance, notified its staff that all employees who joined the army or navy would on their return be reinstated in their present positions, or if necessary found employment with some other suitable company. The London County Council has guaranteed half pay to all men now in its service who have been called out and are married or have dependent relatives. The Council has also guaranteed to reinstate such men without loss of seniority. The British Electrical Federation, which includes about forty tramways and electric companies, has established a fund for the relief of dependents of tramway and electric supply men called for service. Under the conditions of this fund the companies subscribe an amount equal to the total contributions made by the employees who remain at work. The contributions are not in any case to be less than 3d. per week for each man in the employ of the company. The companies included in the federation have also indicated that in the event of a reduction in service becoming necessary they will endeavor to equalize the work so as to prevent a reduction in the staff.

The London County Council Tramways are reported to have lost 700 men through enlistment out of a total of 12,000 employees. Of the employees of the London General Omnibus Company, 2000 men have been called. The last company has also had a number of its omnibuses taken temporarily by the military authorities for transport purposes. The buses of the Norwich Electric Tramways were also commandeered. From Glasgow it is reported that 600 employees of the Municipal Tramways have been called. In Leeds, more than 250 men have joined the government forces; in Sheffield, about 140 men; in Cardiff, more than 100 men; in New Castle-on-Tyne, about 120 men; in Ipswich, 33 men; in Liverpool, about 400 men; in Birmingham, about 340 men; in Salford, about 90 men. The London County Council Tramways has reduced the number of cars and has suspended for the time being the stipulation fixing the number of passengers to be carried on each car.

A recent report from Berlin states that about 800 women are employed as conductors on the Grosse Berliner Strassenbahn. It is stated that these women are members of the families of employees now at the front.

A message from Brussels under date of Aug. 24 stated that the German forces occupying that city are collecting the gross earnings of the local street railways. It was not stated, however, whether any of the earnings are being devoted to wages and the purchase of supplies. It is hardly likely that the gross earnings of the Brussels Tramways would pay even for these items under the present conditions.

ILLINOIS TRACTION SYSTEM IMPROVEMENTS

Improvements on the Illinois Traction System under way at the present time include the reconstruction of the overhead lines between Danville and Champaign, Ill., and raising the transmission voltage to 33,000 to conform with that on the rest of the system. These overhead lines are on the oldest section of track on the Illinois Traction System and were of spanwire construction. In the new construction 10-ft., 6-in. arms are applied to 40-ft. poles. The three-phase, 33,000-volt, high tension lines are carried on the same poles on a 10-ft. cross-arm with 45,000-volt, three-petticoat insulators. All poles and the high tension cross-arms are being treated with creosote. At a number of points the old alignment is being straightened. These include the entrances to Urbana and Champaign. In both of these cities freight haulage has been restricted materially owing to several sharp curves at street intersections. Other improvements include the installation of four interlocking plants on the line between Springfield, Ill., and St. Louis, Mo. These plants will provide protection at steam road crossings. They include a standard manually operated interlocking system. The towers conform to the standard substation design. This includes a dark red paving brick base with buff pressed brick walls and a red tile roof.

CONSTRUCTION PROGRESS ON BOSTON SUBWAYS

Steady progress is being made at Boston in the construction of the subways now being built under the direction of the Boston Transit Commission. The Boston Elevated Railway is making vigorous efforts to complete the installation of track and electrical equipment in the Boylston Street subway so that this line may be opened early in the fall, and enlargements of the Park Street subway station are expected to be completed in December. Work is being rushed on the inclined subway approach at the Public Garden, the eastbound track connecting the surface car lines of the Back Bay with the Public Garden subway spur now being in service. It has been decided to employ blue and maroon color schemes in the Copley and Massachusetts stations of the Boylston Street subway, as in the Washington Street tunnel. The Boylston Street subway differs from earlier tubes in Boston in its roof construction, which is flat with rounded corners. Rock-ballasted track will be used throughout. At the stations parallel and opposite platforms with short stairways connecting with lobbies and the streets will be in use. It is expected that the running time between the Charlesgate district and Park Street will be cut from fourteen to eight minutes by this subway. The West End subway extension from Scollay Square will increase the traffic capacity of the East Boston tunnel from 80 to 250 cars an hour, and will probably be completed in about eighteen months. No date has yet been set for the opening of the Cambridge subway extension to the South Station, but contracts have now been let for the sections not previously placed under construction, and rapid progress is being made on the work between Park Street and Church Green. A station will be provided in this subway which will afford close connections with the Washington Street tunnel, with inclined elevators leading to Hawley and Chauncey Streets.

NOTICE TO DISCONTINUE LOCAL BRIDGE SERVICE

Bridge Commissioner Kracke of New York has served on the Brooklyn Heights Railroad, the Bridge Operating Company, the Coney Island & Brooklyn Railroad and the New York Railways an order terminating the contract under which the local service over the Williamsburgh Bridge is operated. The contract, dated Sept. 1, 1904, terminated on Sept. 1, 1914. Under its terms, the operation of cars upon the surface tracks is to be continued until one year after the notice to stop. The formal notification to the companies was as follows:

"Pursuant to Sec. 3 of the agreement, dated May 21, 1904, between the city of New York and the Brooklyn Heights Railroad, Coney Island & Brooklyn Railroad, New York City Railway and the Bridge Operating Company, you are notified to cease operation of cars upon the surface tracks upon the Williamsburgh Bridge, across the East River, from and after midnight on Aug. 31, 1915."

Commissioner Kracke considers the profits of the company on this contract have been disproportionately large. The capitalization of the Bridge Operating Company is $100,000.

TOLEDO NON-PARTISAN LEAGUE DESIRES ACTION

The Non-Partisan League of Toledo, Ohio, is growing restive under the delay of the franchise committee of the City Council in taking action upon the franchise draft submitted by it some time ago. It is said that the organization may take steps to have the proposed franchise submitted to a vote of the electors, if something is not done soon by the committee. After two meetings with the league, the committee decided to discuss the matter in executive sessions and the organization was informed that its members would be sent for when wanted. The same information was given the Toledo Citizens' Franchise Association, which also has a franchise draft pending in the committee.

So far as known, nothing has been done with the municipal ownership ordinance which was passed by a referendum vote of the people some time ago. It is possible that the franchise committee of the City Council is awaiting the outcome of the injunction suit recently brought by the company to prevent the city from interfering with it in the operation of its cars at the old fare and from removing its cars. The hearing in this case will take place before Judge Killits on Sept. 8.

The Toledo Railways & Light Company has appealed a case from the city courts, in which there is some interest. In this suit William Jacobs, business agent of the Moving Picture Operators' Union, claimed that he and two large grips which he carried were put off a car when he proffered 3 cents for fare. He asked for $300 damages and was awarded $100 in the city court. Attorneys for the company argue that Jacobs was not put off the car, but that the grips were put off because he refused to pay extra for them. This would seem to resolve itself into the question of whether the road is under obligations to carry baggage for its passengers.

Public Service Railway Franchise Tax.—The amount of the tax paid recently by the Public Service Railway into the city treasury of Newark, N. J., was greater than that paid last year and not less as stated in the ELECTRIC RAILWAY JOURNAL for Aug. 29, page 387. The amount paid in 1914 was, as stated, $173,976.99, and the amount paid in 1913 was $168,920.13.

California Report on Inductive Interference.—The Railroad Commission of California has just made public the results of an exhaustive investigation into the subject of inductive interference caused by high-voltage power lines. The work was conducted by a committee of electrical engineers selected from the larger public utilities of the State and the commission's engineering staff. The problem which this committee, working with the Railroad Commission, was called upon to solve, briefly stated, relates to the regulation and control of stray electrical currents from high-voltage power wires.

Service Improvements in Pittsburgh.—Mayor Joseph G. Armstrong of Pittsburgh, Pa., has sent to the City Council a communication announcing that an early settlement of the controversy with the Pittsburgh Railways seems likely. He says that several conferences have been held and that satisfactory progress is being made. The city recently presented to the company a series of suggestions in regard to improvements it thought the company should make in its service, intimating that unless the city and the company were able to reach a satisfactory adjustment the case would be carried to the Public Service Commission.

The Public as Guests in McAlester.—In connection with its application for extended franchise rights for its power and light service the Choctaw Railway & Lighting Company, McAlester, Okla., recently invited the public to be the guests of the company in an inspection of its plant and equipment. A special day was set aside for the inspection and free transportation was furnished to the company's plants over its own lines. Those who desired to take advantage of the offer of the company were requested to communicate with the company direct or with its representative who was stationed in one of the prominent downtown drug stores.

Newark Terminal Work Delayed.—The following statement has been made by E. W. Hine, secretary of the Public Service Corporation of New Jersey, Newark, N. J., in regard to the proposed suspension of work on the company's new electric railway terminal in that city: "We have discontinued work on the terminal part of our building plans, but work on the tunnel will be continued and pushed to completion. As a measure of prudence we made overtures to Hedden & Company and it was by mutual agreement that work under the contract will be temporarily suspended. This does not mean an abandonment of work by any means." The contract on which operations have been interrupted calls for an expenditure of $700,000. While the structural plans were in progress arrangements were under way to have the bonds of the newly formed Terminal Railway Corporation floated. The uncertainty of making a satisfactory disposition of these bonds made the present action seem prudent.

Service Resumed in Vincennes.—Owing to the effects of a Federal Court injunction, the Vincennes (Ind.) Traction Company has been operating normally. The temporary restraining order, which named some twenty-eight individuals and "all others," not only requires the twenty labor unions to use their influence against violence, but it requires the Mayor and the police department to protect the company and requires the company to maintain service. On Aug. 26 the temporary order was continued indefinitely by Federal Judge F. E. Baker, who heard the case at Indianapolis. Commenting on the order, the court said: "It means that every citizen of Vincennes and Knox County must obey it, and I hope all these defendants will go home and obey it." In this case S. S. Bush and S. A. Culbertson, Louisville, Ky., owners of a majority of the stock of the Vincennes Traction Company, took the case to the Federal Court, out-maneuvering Mayor James M. House, who sought a writ in the State courts disadvantageous to the company. The company has 9 miles of track and employs about fifty trainmen.

PROGRAMS OF ASSOCIATION MEETINGS

Kansas Gas, Water, Electric Light & Street Railway Association

The date of the annual meeting of the Kansas Gas, Water, Electric Light & Street Railway Association, which was scheduled for Oct. 15, 16 and 17, has been changed. In order to avoid a conflict with the annual meeting of the Jovian Order to be held in St. Louis, the Kansas Association has postponed its meeting until Oct. 22, 23 and 24. The convention will be held at Arkansas City.

New England Street Railway Club

The annual ladies' outing of the New England Street Railway Club will be held at Bass Point, Nahant, Mass., on Sept. 10. The trip from Boston will be made on the steamers of the Boston, Nahant & Pines Steamship Company. This route offers a delightful sail of one hour each way. The party will leave Boston from Otis wharf at 440 Atlantic Avenue at 9.30 a.m., but tickets will be good on any of the regular boats. The return will be made from Bass Point at 6.30 p.m. At noon a shore dinner will be served at the Relay House. After dinner there will be dancing in the pavilion, box bowling and regular bowling, all free. The Nahant & Lynn Street Railway will provide free transportation for those who attend. Boats will also be provided for those who desire to try their hand at deep-sea fishing. Tickets, including all attractions, are $2.50 each. The club desires that requests for tickets be filed with the outing committee, 12 Pearl Street, Boston, as early as possible. The members of the outing committee are J. E. Dozier, H. B. Ivers, W. W. Field and H. A. Faulkner.

National Tax Association

Final plans are announced for the eighth annual conference of the National Tax Association to be held at Denver, Sept. 8-11. A special train over the Burlington Road, leaving Chicago Sept. 7, will take the eastern delegates. The program this year contains the following papers and reports of particular interest to the electric railway field:

"Tax Legislation and Important Court Decisions in the Past Year," by M. M. Flannery, chief tax division, Bureau of Corporations.

"Taxation of Securities." by W. H. Lyon, counsel to committees, Investment Bankers' Association of America.

"The Federal Income Tax Law," by C. J. Bullock, professor of economics, Harvard University.

"Simplification of the Federal Income Tax Law," by A. C. Rearick.

"Administrative Problems of the Federal Income Tax," by L. F. Speer, deputy commissioner of internal revenue, Treasury Department.

"Work and Possibilities of Public Efficiency Bureaus," by W. H. Allen, director Bureau of Municipal Research, New York.

"Report of Committee on Double Taxation and Situs for Purposes of Taxation."

In addition to the above papers on the federal income tax, there will be a general discussion on this subject, in which Prof. E. R. A. Seligman of Columbia University, the leading authority on the subject, K. K. Kennan, Milwaukee, and Ralph Norton, New York, as well as many other students and professional men who are especially interested, will participate.

A session will be devoted to efficiency and economy in governmental affairs, participated in by Wm. H. Allen, John L. Coulter of the Federal Census Bureau and E. Dana Durand, former director of the census. The practical questions will center about the facts as to increase in expenditures, the propriety of checking them and the means and methods of doing this. Another session will be devoted to the recent movements toward increase in land taxation involving a critical review of experiments along this line both in Canada and in the United States.

Prof. E. R. A. Seligman is president of the association and T. S. Adams, tax commissioner of Wisconsin, is secretary. Delegates have been appointed by practically all the states and by Canadian provinces.

Financial and Corporate

RECENT FINANCIAL TENDENCY

All Proposed Moves Weighed Carefully—Decision Against Restricted Bond Transactions—Clayton Bill Passed

There has been no significant change in financial conditions in New York during the week. All proposed moves are weighed cautiously as to their immediate and ultimate effect. Even the plan to resume trading in bonds has been abandoned for the present. This matter was taken up by representatives of a number of the leading bond houses. After several conferences it was decided that it would be unwise to take any action at this time looking to the resumption of even restrictive dealings. It is generally understood that this decision was reached after a conference with the committee of the Clearing House.

A conference was scheduled to be held in Washington on Sept. 4 between the members of the Federal Reserve Board and committees of bankers from New York and other cities. It was expected that it would be proposed at this meeting that the government contribute relief to the international exchange situation by placing at the disposal of the banks $30,000,000 in gold for the specific purpose of easing the international exchanges. The proposed adoption at this conference of the plan for opening up the exchange market would help materially the work of financing international trade.

The settlement on the London Stock Exchange of the business which was left open when trading came to an end has been further postponed as a result of the extension of the English moratorium. The Paris Bourse on Sept. 2 ceased the very limited operations in securities in which it had been engaged since the war. On the other hand, on the same day, it was reported from Berlin that the governors of the Bourse there had under consideration a plan to resume trading in a number of issues. So far no steps have been taken in New York to make public the cash transactions which are conducted through the clearing house of the exchange. On Sept. 2 in New York call money was at 6 @ 8 per cent. Sight drafts on London were quoted about $5.06½, while cable transfers were quoted about $5.07½.

The Senate on Sept. 2 passed the second number on the administration's anti-trust program—the Clayton bill supplementing the Sherman act. The bill provides fines and imprisonment for officers of corporations convicted of offenses against the trust laws; prohibits exclusive and tying contracts which restrict independence of purchasers; prohibits holding companies where their effect is to lessen competition or create monopoly, and makes illegal two years after the passage of the act interlocking directorates in competing corporations any one of which has a capital of more than $1,000,000. It also forbids the interlocking of railroad directors with corporations dealing in securities, railroad supplies, or contracts, and liberalizes procedure in injunction and contempt cases. Directors of railroads under the terms of the bill cannot be interlocked with corporations dealing in securities, railroad supplies, or other articles of commerce or contracts for construction, maintenance, etc., to an amount of more than $50,000 in any one year unless purchases are made after competitive bidding under recommendations of the Interstate Commerce Commission. A penalty of two years' imprisonment and $25,000 fine is prescribed for violation. As the President has practically consented to the abandonment of the railway securities bill for this session, at least, the Clayton bill is the last of the regular measures on the legislative program for the present session.

Much has been written about the difficulties of new financing. Figures now available show that for August the total was only $12,000,000, compared with $40,000,000 for August, 1913, which was the low month last year. Of this $12,000,000 $6,000,000 was new capital and $6,000,000 refunding. The total of $1,095,000,000 for the first eight months of the current year was $191,000,000 less than the amount for the same period in 1913 and $387,000,000 less than in 1912.

A review of conditions among some of the principal manufacturers who furnish equipment and supplies to the electric railway industry is published elsewhere in this issue.

ANNUAL REPORTS

United Railroads of San Francisco

A statement of income, profit and loss showing the correct method of accounting for the United Railroads of San Francisco, San Francisco, Cal., for the period of approximately nine years from Jan. 1, 1906, to June 30, 1914, has been issued by Mason B. Starring, president United Railways Investment Company, which controls the United Railroads of San Francisco. This statement, which was prepared and certified by Haskins & Sells, is as follows:

Operating revenue		$61,763,681
Operating expenses		38,708,143
Net operating revenue		$23,055,538
Other income:		
Sinking fund earnings		$860,273
Discount and interest		343,303
Miscellaneous		142,045
Total		$1,345,621
Total income		$24,401,159
Deductions from income:		
Interest and discount		$992,286
Rentals and leases		538,508
Total		$1,530,794
Net income before deducting fixed charges		$22,870,365
Fixed charges:		
Interest on United Railroads securities		$8,856,859
Interest on underlying bonds		6,549,839
Total		$15,406,698
Net income		$7,463,667
Profit and loss credits:		
Surplus at beginning of period		$1,217,932
Amount transferred from sinking fund reserves on account of sinking fund investments made during the period—net		1,207,821
Miscellaneous		56,967
Total		$2,482,720
Profit and loss gross surplus		$9,946,387
Profit and loss charges:		
Depreciation charges:		
Loss account earthquake, fire and strike		$1,646,472
Less face value of 12,000 shares of common capital stock reacquired through contribution		1,200,000
		$446,472
Reserve for depreciation, renewals and contingencies		2,678,588
Loss on buildings, equipment and materials		800,569
Total depreciation charges		$3,925,629
P. Calhoun's note written down (Solano land matter)		1,096,110
Loss on Panama Pacific Exposition stock		79,998
Loss on securities bought and sold—net		137,007
Appropriations and adjustments:		
For contingencies	$100,000	
Miscellaneous—net	44,009	
		$144,009
Dividends:		
First preferred stock (7 per cent—1909, 1910, 1911, 1912, 1913; 3½ per cent—1914)	$1,925,000	
Preferred stock (1906—$1,120,000; 1913—$200,000)	1,320,000	
Common stock (1906)	300,000	
		$3,545,000
Total		$8,927,754
Profit and loss surplus at end of period		$1,018,632

London County Council Tramways

During the year ended March 31, 1914, the income from the electric lines of the London County Council Tramways was £2,247,042. The working expenses were £1,585,251, thus leaving a surplus of £661,791. On the horse lines the income was £21,625 and expenses £30,214, a deficiency of £8,589. The total income was £2,268,668 and expenses £1,615,466, a surplus of £653,202. Interest absorbed £328,109 and redemption £408,488, and after deducting the income tax of £28,196 and making various other adjustments the deficiency to be met out of the general reserve fund was £88,526.

The Council decided on June 23, 1908, that for five years provision should be made for renewals at the rate of 2-3d. per car-mile each year and also that a general reserve fund to provide for general contingencies should be established, to which any balance remaining, after providing fully for renewals, should be carried. In view, however, of the falling off in the traffic receipts, the Council decided on July 8, 1913, that for two years from April 1, 1913, any available surplus should be paid into the renewals fund. In 1912-1913 the sum available for transfer to the fund was £497, while for 1913-1914 there was no sum available. The fund on March 31, 1914, amounted to £539,749. If full provision had been made for renewals on the basis of 2-3d. per car-mile, the fund would have received about £165,000 for the past year. There was no balance available to be carried to the general reserve fund for 1912-1913 and for 1913-1914, but the fund has to be drawn upon to the extent of £88,526 to meet the present deficiency. The fund now amounts to £190,596. The poor condition of the company is mostly laid at the door of motor omnibus competition.

The London County Council has ordered 150 trailers and the equipment of 200 electric cars with couplers and traction gear for drawing trailers. The highways committee estimates that the cost of operating a trail car is £338 a year less than that for an ordinary electric car. The total number of passengers carried on the electric cars during the fiscal year was 516,338,859, and the number of car-miles run 58,572,356; on the horse cars the numbers were 6,613,781 and 636,933, making the totals 522,952,640 and 59,209,289 respectively. The capital expenditure on the undertaking up to March 31, 1914, amounted to £13,028,119, of which £409,276 represented expenditures in 1913-1914.

Cities Service Company

Based upon an examination made by Price, Waterhouse & Company of the books of the Cities Service Company, New York, from the time of its organization up to and including April 30, 1914, and also of a substantial portion of the subsidiary companies for the twelve months ended the same date, the income statement of the Cities Service Company for the year ended April 30, 1914, is as follows:

Company's proportion of earnings applicable to common stock of subsidiary companies	$2,836.931
Dividends on preferred stocks of subsidiary companies	21,221
Interest on bonds of subsidiary companies	176,607
Interest on bills and accounts receivable	293,772
Total	$3,328,531
General and administrative expenses	$65,879
Interest on bills and accounts payable	97,598
Interest on five-year 7 per cent convertible gold notes	246,685
Interest on Consolidated Cities Light, Power & Traction Company 5 per cent bonds	175,000
Total	$585,162
Profits	$2,743,369
Deduct—dividends paid:	
Preferred	$1,202,242
Common	646,329
Total	$1,848,571
Balance, transferred to surplus account	$894,798

The above balance includes the company's proportion of earnings applicable to common stock for six months on the properties acquired from the Utilities Improvement Company and the Consolidated Cities Light, Power & Traction Company. It is stated that the gross earnings of the subsidiary companies examined aggregated about 60 per cent of the total gross earnings. The accountants' examination showed the records of the Cities Service Company to be correct for the period and, subject to depreciation, the examination of the books of the subsidiary companies did not indicate the necessity of any other than minor adjustments.

The company has also issued a comparative statement of earnings for the years ended July 31, 1914 and 1913, as follows.

	1914	1913
Gross earnings	$3,543,736	$1,487,344
Expenses	97,269	74,582
Net earnings	$3,446,467	$1,412,762
Interest on notes	320,991	17,904
Net to stock	$3,125,476	$1,394,858
Dividends on preferred stock	1,422,124	699,305
Net to common stock	$1,703,352	$695,553
Dividends on common stock	702,686	326,354
Net to surplus	$1,000,666	$369,199

The above statement covers three months on the old basis and nine months on the new basis after the Cities Service Company acquired the Utilities Improvement Company and the Consolidated Cities Light, Power & Traction Company. There is a deduction of $22,184 for surplus reserve which was not featured in any of the previous statements, but which it has been deemed advisable as a conservative measure to create as a depreciation fund in addition to the regular maintenance charges. In this last report the total surplus is $2,755,718, as compared with $2,626,869 in the report of the company for April 30. The percentage earned on the average amount of common stock outstanding is 11.73 per cent, as compared with 11.42 per cent on April 30.

LOCAL TRACTION OWNERSHIP

Change in Common Stock Ownership of New England Investment & Security Company Sought

A preferred shareholders' protective committee, consisting of Henry B. Cabot, Moses Williams, Jr., and Eugene V. R. Thayer, of Boston, has been formed with a view to purchasing all the $100,000 of common stock of the New England Investment & Security Company, which was acquired in August, 1913, by Sanderson & Porter, as noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, 1913. A statement has been issued by the protective committee in part as follows:

"The public of Worcester, Springfield and other communities served by the New England Investment & Security Company's electric railways will be interested in the report that a movement has been begun among preferred shareholders to restore those properties to local ownership and control. The organization of this company is peculiar. The owners of 1000 common shares select four of its seven trustees, and the owners of the 40,000 preferred shares select only three. For several years all these properties, operating about 420 miles of street railways, have been controlled, now by one set of owners of common stock and now by another set—the whole common representing a par value of only $100,000. The preferred stock, largely held by investors in Springfield, Worcester and Boston and of a par value of $4,000,000, has been legally in the position of a minority.

"The preferred stockholders have become uneasy at this anomalous situation and now influential ones have been led to form a protective committee. This proposes, if sufficient shareholders join in the plan, to purchase in the interest of the preferred shareholders all of the common stock. The Merchants' National Bank of Boston is the depositary of the committee and the protective agreement is lodged with that bank.

"Any preferred shareholder may become a party to the agreement by subscribing to the same at the office of the depositary and agreeing to pay such amount not exceeding $10 per share as the committee may call for. The committee reserves the right to abandon the plan for the purchase and to return to the subscribers the amount of their several subscriptions (less expenses, not to exceed 50 cents per share) unless the holders of at least three-fourths of all outstanding preferred shares become partners to the agreement."

One of the objects of the purchase, in addition to securing home control, is said to be a simplification of the present elaborate financial structure of the companies concerned. The New England Investment & Security Company was owned and controlled for years by the New York, New Haven & Hartford Railroad until the latter was forced by the United States government to dispose of some of its holdings in New England. At present there are two voluntary associations and seven corporations concerned in the electric railway situation around Springfield and Worcester. The Worcester Railways & Investment Company controls the Worcester Consolidated Street Railway, which in turn leases the Worcester & Webster Street Railway and the Webster & Dudley Street Railway. The New England Investment & Security Company controls the Worcester Railways & Investment Company and also directly controls the Springfield Street Railway, the Milford, Attleboro & Woonsocket Street Railway, the Interstate Consolidated Street Railway and the Attleboro Branch Railroad. The Springfield Street Railway is a consolidation of the Western Massachusetts Street Railway and the Springfield & Western Street Railway. The presumption is stated to be that if all the holders of the preferred shares of the New England Investment & Security Company take part in the purchase of the common stock it will be possible to simplify the situation, possibly through the formation of a new corporation.

American Public Utilities Company, Grand Rapids, Mich.—At the annual meeting of the American Public Utilities Company, John H. Blodgett and W. J. Ripley were elected to succeed H. L. Mason and W. H. Snow respectively on the board of directors. W. J. Ripley was elected assistant secretary and treasurer. The executive committee is composed of John H. Brewer, chairman; C. B. Kelsey, C. A. Boaldt, J. S. Hart, G. C. Whitworth, Charles McPherson and Blaine Gavett.

Chicago (Ill.) Elevated Railways.—In connection with the deferring of the quarterly dividend of 1½ per cent on the 160,000 of 6 per cent cumulative preferred shares of the Chicago Elevated Railways, noted in the ELECTRIC RAILWAY JOURNAL of Aug. 29, Henry A. Blair, member of the board of trustees, has issued the following statement: "We could only expect that a European war would affect the demand for manufactured goods, and in view of the extent of the conflict I think Chicago conditions, generally, are satisfactory. The manufacturing district has been hit heavily by the war. This conclusion is reached by reports from our investigators who find that most of the losses in traffic of the Chicago Elevated Railways have occurred in the factory district. A good part of this loss, however, may be caused by the fact that a large number of foreigners elegible to bear arms for their native countries have come to the Atlantic seaboard with the expectation of getting back home. For about ten years we have been showing an average increase in receipts of from 7 per cent to 8 per cent. Since the depression in business occurred, that is in the past three weeks, our receipts have shown a falling off and the rate of increase over the corresponding period of last year has dropped to approximately 1 per cent. This shows that even with poor business prevailing we are still able to keep our receipts above those of last year."

Cincinnati, Newport & Covington Light & Traction Company, Covington, Ky.—The shareholders of the Cincinnati, Newport & Covington Light & Traction Company voted on June 25 to authorize an issue of $200,000 of first mortgage sinking fund twenty-five year 5 per cent bonds by the Licking River Bridge Company to cover the cost of reconstructing the Eleventh Street bridge between Covington and Newport. The new bonds, which are not yet sold, will be guaranteed by the Columbus Gas & Electric Company and the South Covington & Cincinnati Street Railway.

Hudson & Manhattan Railroad, New York, N. Y.—The directors of the Hudson & Manhattan Railroad on Sept. 1 declared the interest earned on the adjustment income mortgage bonds for the six months ended June 30, 1914, at the usual rate of 2 per cent per annum, or $10 per $1,000 bond, payable Oct. 1, 1914. The balance of net income for July available for interest on the adjustment bonds was $40,333, an increase of $10,318 over July, 1913. The number of passengers carried during July was 4,653,546, compared with 4,367,764 during the same month of the previous year.

New York (N. Y.) Railways.—Theodore P. Shonts, president of the New York Railways, announced on Sept. 2 that the company had prepared a summarized statement showing that the net income payable as interest on the adjustment mortgage bonds for the six months ended June 30 amounted to 1.24 per cent; also that the mortgage provided that such a statement must be signed by three-fourths of the directors elected by the bondholders; that the unavoidable absence in Europe of one of the directors representing the bondholders and the refusal of another to sign the approval made it necessary to agree with the trustee of the mortgage upon the selection of a board of experts to ascertain the income; that the directors had authorized the necessary procedure, and that there probably will be no delay in the interest payment due on Oct. 1.

Norwood, Canton & Sharon Street Railway, Canton, Mass.—The Norwood, Canton & Sharon Street Railway has petitioned the Massachusetts Public Service Commission for the approval of an issue of $300,000 of first mortgage 5 per cent twenty-year bonds to retire an equal amount of capital stock.

Pacific Gas & Electric Company, San Francisco, Cal.—The Pacific Gas & Electric Company has made application to the California Railroad Commission for authority to issue $1,000,000 of general and refunding mortgage gold bonds to be used in connection with the filing of certain surety bonds amounting to $700,000. The bonds will be filed with the United States District Court clerk to insure the payment of sums which the company may require it to pay in connection with the suit brought by the company to restrain the city and county of San Francisco from enforcing the gas and electric rates provided for in certain ordinances adopted June, 1913.

Portland Railway, Light & Power Company, Portland, Ore.—Application has been made to the New York Stock Exchange by the Portland Railway, Light & Power Company to list $1,064,000 additional first and refunding 5 per cent sinking fund mortgage convertible coupon bonds, series A.

Salt Lake Light & Traction Company, Salt Lake City, Utah.—The Salt Lake Light & Traction Company was recently incorporated in Utah with $1,000,000 of authorized capital stock. The incorporators of the company are O. J. Salisbury, president; J. D. Walker and C. W. Johnson, vice-presidents; A. H. Parsons, secretary, and S. A. Whitney, treasurer. There have been reports that the Utah Power & Light Company is to take over the Utah Light & Railway Company, now controlled by the Union Pacific through the Oregon Short Line, but it is understood that negotiations had not been consummated and that the Utah Light & Railway Company will be purchased by this new company, which is said to be organized by J. C. Jackling, president of the Utah Power & Light Company. The Union Pacific Railroad desires to sell its street railway, lighting and power properties in order to carry out its segregation plans. The probability is that if the control passes to Mr. Jackling and his associates a separation would be made of the lighting and power properties and the street railways. The electrical distribution would then be sold to the Utah Power & Light Company and the street railways operated separately.

Titusville (Pa.) Electric Traction Company.—The rights, franchises and holdings of the Titusville Electric Traction Company were sold on Aug. 27 by Receiver W. J. Smith to Fred W. Garvin, New York City, for $225. Besides the payment of this price, however, the new owners buying the road are said to have accepted debts and obligations exceeding $300,000.

Wisconsin-Minnesota Light & Power Company, Eau Claire, Wis.—The Wisconsin-Minnesota Light & Power Company, successor to the Chippewa Valley Railway, Light & Power Company, has declared the regular quarterly dividend of 1¾ per cent on its preferred stock, payable Sept. 1 through the Boston Safe Deposit & Trust Company. This is the initial dividend under the new organization.

York (Pa.) Railways.—With a capital stock amounting to $1,361,500, a large corporation is being formed to provide most of the electrical service for York and a considerable portion of York county. The new company, known as the Edison Light & Power Company, will include the Edison Light & Power Company, the Merchants' Electric Light, Heat & Power Company, the Lower Windsor Township Light, Heat & Power Company, the Spring Grove Light, Heat & Power Company, the Jackson Township Light, Heat & Power Company, and the Heidelberg Township Light, Heat & Power Company. The last-named six companies, recently organized by the Edison company, are now applying for charters. Providing the application for the merger of the companies is granted by the Public Service Commission, the corporation will be managed by the York Railways through stock ownership. The city voted by ordinance to approve the merger plan on July 3. The city will receive 3 per cent of the gross receipts of the new company, whereas at the present time it receives only that amount of the gross receipts of the Merchants' Electric Light, Heat & Power Company.

DIVIDENDS DECLARED

Brooklyn Rapid Transit Company, Brooklyn, N. Y., quarterly, 1½ per cent, preferred.

Galveston-Houston Electric Company, Galveston, Tex., 3½ per cent, common; 3 per cent, preferred.

Louisville (Ky.) Traction Company, quarterly, 1 per cent, common; 2½ per cent, preferred.

Frankford & Southwark Passenger Railway, Philadelphia, Pa., $4.50, quarterly.

Second & Third Streets Passenger Railway, $3, quarterly.

Traffic and Transportation

TRAINMEN UNDER CIVIL SERVICE

San Francisco Municipal Line Prescribes Difficult Tests for Trainmen—Experience Rated Low

A written examination of applicants for appointment as motormen on the San Francisco (Cal.) Municipal Railway was scheduled to be held in San Francisco on Aug. 29 and for conductors on Sept. 5. The matter of the selection and appointment of trainmen was put in the hands of the civil service commission to keep politics and the "personal element" from being injected. The men were to take the physical examination and the medical examination first, and then, on the dates announced, were to be quizzed under civil service supervision. Thus when C. A. Cashin, superintendent of the railway, wants additional men he will call on the civil service commission and will instruct the men assigned to him in car operation on an unused spur track. He has purposely rated experience low so as to encourage "green" men, as he says he would prefer to break in his own force. About 300 platform men will be needed to operate the lines now under construction. More than 3000 men applied to take the examinations.

The general rules laid down for the examination by the Civil Service Commission follow:

"1. Scope for motormen—Subjects and weights on a scale of 100: General knowledge of duties, 20; equipment and its care, 20; writing of report, 15; arithmetic, 5; athletic test, 35; experience, 5.

"2. Scope for conductors—Subjects and weights on a scale of 100: General knowledge of duties, 30; writing of report, 15; arithmetic, 15; athletic test, 35; experience, 5.

"Each of the above subjects will be rated on a scale of 100: By multiplying the rating by the weight the percentage on a subject is secured. By dividing the sum of the percentages by the sum of the weights the general average percentage is obtained. For the examinations named in this circular the minimum general average percentage for eligibility will be 70.

"The written examination for motormen will be held in the Mission High School Building, Eighteenth and Dolores Streets, on Aug. 29, 1914, at 1.30 o'clock. The written examination for conductors will be held in the Mission High School Building on Sept. 5, 1914, at 1.30 o'clock. If the school building named will not accommodate all the applicants, other school buildings will be used also. The athletic tests will be held in the Southside Playgrounds, Seventh and Harrison Streets, beginning on Aug. 17, 1914.

"Persons filing applications for examination as motormen will be furnished with a copy of the circular containing the questions and answers covering the subjects 'general knowledge of duties' and 'equipment and its care,' and those filing applications for examination as conductors will receive a copy of the circular containing questions and answers relating to the subject 'general knowledge of duties.' Applicants are expected to study these circulars, as the questions in the written examination on said subjects will be taken from the circulars.

"'Writing of report,' in both examinations, will be a test of the applicant's ability to write a correct report on subjects to be named by the commission and will be rated on form and substance.

"The subject 'arithmetic' in both examinations will consist of primary examples covering common and decimal fractions.

"The 'athletic test' in both examinations will consist of the following exercises:

1. Ladder work—Hand over hand on ladder, up and down five rungs. Mark, 10 credits.

2. Lifting 40 lb. dumbbell—Five consecutive lifts with each hand. Lifts to be made from the lowest reach of arm to highest reach, without aid of jerk or swing, while standing erect with feet close together. Perfect mark, 10 credits.

3. High jump—3 ft. 4 in., 10 credits; 3 ft., 5 credits. Use of springboard will not be permitted.

4. Vaulting the horse—Perfect vault over horse 3 ft. 10 in. high, without touching it with any part of body excepting the hands, 10 credits; good vault, 7½ credits; fair vault, 5 credits.

5. Dipping on parallel bars—Two dips, 5 credits each. Dips must be made with legs straight and without assistance of kick or swing.

6. Carrying 125-lb. sack of sand—Sack must be lifted from floor, placed on shoulder and carried up and down six steps. Mark, 10 credits.

7. Running—(Distance about 145 yd.):

Time	Credits	Time	Credits
21 seconds	40	25 seconds	30
22 "	38	26 "	26
23 "	36	27 "	22
24 "	34	28 "	15

(Fifth-seconds will be rated proportionately.)

"Applicants taking the two examinations named in this circular need appear but once for the athletic test, as they will be rated in both examinations from the one athletic record. Candidates who fail to appear for the athletic test will be barred from further examination.

"The subject 'experience' will be rated as follows: Three years' experience had in San Francisco as a motorman of railway cars, 100 credits; two years, 80; one year, 60. Experience as a motorman of railway cars had outside of San Francisco, but within the State of California, will be rated 10 per cent less than experience had in San Francisco, and such experience had outside of California will be rated 20 per cent less than experience had in this city.

"Experience as a conductor will be rated in the same manner as is provided above for rating experience of motormen.

"Applicants must be in sound bodily health and, before appointment, must pass a medical examination before physicians appointed by the commission. Candidates who secure places on the eligible lists and who fail to pass such medical examination will be removed from the eligible lists. Candidates who are unable to hear with each ear, ordinary conversation at a distance of 20 ft., or who are unable to read, without glasses, with each eye, at a distance of 20 ft., letters on Snellen's eye chart marked '30,' will be rejected. Applicants taking examination both for motormen and conductors need take but one medical examination.

"Applicants must be citizens of the United States, twenty-one years of age or over, and residents of San Francisco for at least one year next preceding Aug. 17, 1914, the date of the beginning of these examinations.

"Application blanks (Form 40) may be had by applying in person or by mail at the office of this commission, room 341, City Hall, 1231 Market Street. Receipt of applications closes Aug. 13."

Statement of Service Reductions Filed in Cincinnati.—The Cincinnati (Ohio) Traction Company has filed with Service Director Fosdick a list of the proposed reductions in its car service. On the advice of Mayor Spiegel, however, the list will not be made public until a thorough investigation has been made, as the Mayor wishes to avoid precipitating at this time the protests that are likely to follow the public announcement.

Suburban Fare Hearing in Seattle.—The Public Service Commission of Washington has fixed on Oct. 1 as the date for the hearing of the case relative to the rates recently proposed by the Seattle, Renton & Southern Railway, Seattle, Wash. The company, a few weeks ago, filed with the commission a tariff schedule, based on a zone system, which will double the fare from Renton, the terminus of the line, to Seattle. A number of citizens and the city of Seattle protested against the rates and the commission suspended the tariff for ninety days, pending an investigation.

Montreal Picnic Trophy.—Some years ago the Montreal (Que.) Tramways offered a shield as a prize to the station selling the larger number of tickets to the annual picnic of the company's mutual benefit association, the shield to become the permanent property of the station winning it for three consecutive years. As the employees of the Cote Street station sold the greatest number of tickets again this year the shield has become their property. The interest that has been taken in the picnic is shown by the fact that the number of tickets sold at the Cote Street division averaged seventy-four per man.

Resumption of Service Ordered.—The Public Utilities Commission of Ohio has decided against the Hocking Valley Railroad in the matter of the complaint regarding the discontinuance of service operated by electricity by the company since 1896 between Jackson and Hamden, Ohio, a distance of 15 miles. The complainants contended that the service influenced many individuals, firms and corporations to locate in the territory mentioned and that public convenience requires the continuance of the service. The company discontinued service on Aug. 23. It has been directed by the commission to resume its schedule in full on Sept. 15.

Electric Railway Service to New York Markets.—S. C. Van Blarcom, president of the Board of Trade of Paterson, N. J., has notified the New York market committee that his organization and the Public Service Corporation, Newark, N. J., have petitioned Governor Fielder to permit electric railways to operate freight service. The idea is to bring into the New York market fresh produce from within a radius of 50 miles. The sub-committee on transportation, of which D. W. Cooke of the Erie Railroad is the chairman, is arranging with the express companies and the operators of auto trucks to distribute foods brought in in this way.

Accidents in New York in August.—According to the report of the National Highways Protective Society fifty-three persons lost their lives by vehicular accidents on the streets of New York City during August, the same as the corresponding month last year. Twenty-six of this number were children under sixteen years of age. Automobiles caused the death of twenty-nine persons; wagons killed thirteen, and trolleys, eleven. Of the children killed, fourteen met their deaths by automobiles, ten by wagons and two by trolleys. In August, 1913, twenty-six persons were killed by automobiles, twelve by trolleys and fifteen by wagons.

New Freight Tariff on Puget Sound Electric Railway.—The Puget Sound Electric Railway, Seattle, Wash., operating between Seattle and Tacoma, has been granted the right to put into effect special freight rates affecting feed, grain, milk and furniture shipments. Following are the reductions: grain and feed from either Seattle or Tacoma to Kent and Auburn, from 10 cents to 8 cents a hundredweight; milk in 10 gal. cans or larger, from Auburn, Kent and intermediate points to Seattle, from 15 cents to 12 cents a hundredweight; furniture from manufacturing establishments or in compact and large quantities from Tacoma to Seattle or from Seattle to Tacoma, from 20 cents to 10 cents a hundredweight.

"Near-Side" Ordinance in Effect in New York.—The new ordinance, requiring all surface cars to stop for passengers on the near side of a crossing, went into effect in New York on Sept. 1. A rectangular space, extending 8 ft. from the side of the car tracks, has been painted on the pavement on the near side of crossings. Persons may stand within this marked inclosure while a car is approaching without danger from automobiles and other vehicles, which are not to be permitted to pass over such places while cars are approaching or while passengers are getting off them. The first safety zones are being tried on Broadway, between Thirty-fourth and Forty-fourth Streets, and if the system proves successful it will be extended throughout the city.

Reduce Parking of Cars.—By reason of the removal of a large portion of the mechanical department of the Detroit (Mich.) United Lines from the Monroe Avenue shops to the magnificent new workshops in Highland Park the company is now enabled greatly to reduce the parking of cars in the streets. Heretofore interurban cars that were to be held some considerable time before being sent on their runs have been parked at some of the city carhouses while others have been kept on Larned Street and near the old Third Street depot. The majority of such cars together with those staying in Detroit over night now run to the Monroe Avenue property which is known as the Detroit interurban carhouse. This new regulation will not, however, affect those cars that have but a few minutes to wait between their arriving time and their leaving time.

Steam Railroads Increase Passenger Rates.—Following the lead of the Pennsylvania Railroad, the New York, New Haven & Hartford and its associated lines, the Boston & Maine and the Boston & Albany, announced on Sept. 1 a proposed increase in mileage book rates. The three roads have filed new passenger tariffs increasing the old from 2 cents a mile to 2¼ cents. The higher rate will become effective on Oct. 1 if approved by the Interstate Commerce Commission. A hearing also will be held on the matter by the Massachusetts Public Service Commission. In this connection the Lehigh Valley, Pittsburgh & Lake Erie, Lake Shore, Delaware, Lackawanna & Western, and Delaware & Hudson Railroad filed revised tariffs with the public service commissions on Sept. 1 advancing the mileage rate from 2 to 2¼ cents per mile on Oct. 1. Similar action regarding the filing of new rates was taken by the Pennsylvania Railroad and the Philadelphia & Reading Railroad on Aug. 31.

Ruling in Regard to Excess Fare.—On July 31, 1914, the Public Service Commission for the First District adopted an order fixing the maximum fare to be charged for transportation in either direction between Manhattan and Rockaway Park at 15 cents. Complaint had been made to the commission that it was the practice of the operating companies to sell through tickets for 15 cents, but to collect an extra nickel, or 20 cents in all, if a passenger paid his fare on the cars. The order limiting the charge to 15 cents was served upon the operating companies, namely, the New York Consolidated Railroad and the Long Island Railroad and they were directed to answer by Aug. 8. On that date both companies applied for an extension and the commission extended their time to answer to Aug. 21. On this date both companies presented an application for a rehearing. This application was denied and the companies were informed that the order of July 31 should be put into effect immediately.

Strike on Cumberland & Westernport Electric Railway Settled.—The strike of the employees of the Cumberland & Westernport Electric Railway, Cumberland, Md., declared on Aug. 18 on account of the refusal of the company to grant the demand of the men for an increase in wages, has been settled and service was resumed on Aug. 27 at noon. Officials of the company, at a joint conference with the representatives of the employees, at which Frank A. White, chief of the State Bureau of Statistics and Information, was present, agreed to grant the increase. In suggesting that the company comply with the request of the men, Mr. White said he would make every effort, through his bureau, to have the Public Service Commission of Maryland allow the company to adjust its passenger rates so that the advance in the cost of operating the cars can be met. The company's officials maintained that the earnings were not sufficient to warrant the advance. The increase is 1 cent an hour for motormen and 3 cents an hour for conductors.

Traffic Between Kansas City and St. Joseph.—Both passenger and freight service by the St. Joseph & Grand Island Railroad between St. Joseph and Kansas City was discontinued on Sept. 1. The railroad had been using the tracks of the Santa Fê, Quincy, Omaha & Kansas City and the Chicago, Milwaukee & St. Paul Railroads between the two cities, and those contracts have been terminated. J. R. Harrigan, general manager of the Kansas City, Clay County & St. Joseph Railway, the electric railway between Kansas City and St. Joseph, is now negotiating with the Grand Island for its passenger business from St. Joseph southward to and through Kansas City, and for Grand Island business from Southern points and Kansas City. The Kansas City, Clay County & St. Joseph Railway is running limited cars, with only two stops between Kansas City and St. Joseph, and is planning to increase this service four cars each day each way between the two cities. The electric line is 10 miles shorter than any of the five steam roads that now run passenger trains between Kansas City and St. Joseph. The fare by electric railway is 20 cents cheaper than by steam and the running time somewhat less. The electric line reaches the union depot in St. Joseph. Mr. Harrigan is said to feel that an opportunity exists to get much traffic previously handled by the steam roads. The electric railway carried 19,967 passengers between Kansas City and St. Joseph in July, against about 1500 for the steam roads.

Personal Mention

Mr. H. P. Taylor, of H. P. Taylor & Company, Pittsburgh, Pa., has been elected president of the Ephrata & Lebanon Street Railway, Ephrata, Pa., to succeed Mr. A. E. Lane.

Mr. John Johnstone has resigned as general superintendent of the Billings (Mont.) Traction Company. He expects to re-enter electric railway work after a vacation of about three months.

Mr. Charles Monroe Nash, who has been chief clerk to the auditor of the Ohio Electric Railway, Springfield, Ohio, has been appointed an accountant in the southern district of the division of valuation of the Interstate Commerce Commission, with headquarters in the Municipal Building, Chattanooga, Tenn.

Mr. John P. Fox has been appointed transit expert of the committee on city plan of the Board of Estimate and Apportionment of the city of New York. Mr. Fox is well known for his work as investigator for civic betterment clubs, both in this country and Canada. The exact scope of his work for the city of New York is still somewhat indefinite, but one of his first undertakings will be to make a time-zone study of all the transit facilities in the city of New York.

Baron Empain, of Brussels, who was one of the four men said to have guaranteed the payment of $40,000,000 to the Germans as a German war levy, is well known in electric railway circles in Europe. He has long been active as a builder and owner of tramways and interurban lines, his operations being conducted under the unofficial name of the Empain syndicate. Among the larger interurban lines controlled by this syndicate is that centering at Lille, France, which city was also captured by the Germans during the present war.

Mr. C. F. Beames has completed his three-year engagement as chief electrical engineer to the government of His Highness the Maharajah of Mysore, India, having under his charge the operation of the Cauvery power scheme, the largest long-distance high-tension power transmission in operation in the East, supplying power to the Kolar gold fields and the cities of Bangalore and Mysore. Mr. Beames will visit England and return to the United States on or about Oct. 1. He will take up temporary quarters at 55 Highland Avenue, Yonkers, N. Y.

Mr. Howard S. McNair has been elected secretary and treasurer of the American Cities Company, New York, N. Y., with offices in New Orleans, La. Mr. McNair entered railway work in 1903 as a clerk in the office of the superintendent of the New Orleans & Northeastern Railroad. Subsequently he became connected with the Southern Pacific Company, but resigned the latter position in 1906 to enter the engineering department of the New Orleans Great Northern Railroad during the construction of the road. He became connected with electric railway work in 1909 as secretary to Mr. Hugh McCloskey, then president of the New Orleans Railway & Light Company, New Orleans, La. While holding this position Mr. McNair was also assistant secretary and treasurer of the New Orleans Railway & Light Company, and served in other official capacities. He was elected assistant secretary and treasurer of the United Gas & Electric Engineering Corporation on Jan. 1, 1914. He was recently elected secretary and treasurer of the American Cities Company and took up the duties of that office on Sept. 1.

Howard S. McNair

Mr. James N. Hatch, who has been connected with Sargent & Lundy, engineers, for eleven years, has resigned to open an office in Chicago as a consulting engineer. At first Mr. Hatch will devote particular attention to appraisals and valuations. He is associated with Prof. M. E. Cooley in the appraisal of the properties of the Detroit (Mich.) United Railway. Mr. Hatch was graduated from the University of Michigan with the degrees of C.E. and M.E. He is a member of the American Society of Civil Engineers, Western Society of Engineers and of the Engineers' Club of Chicago.

Mr. J. E. Bigham, assistant treasurer of the Tampa (Fla.) Electric Company, was elected president of the Southeastern Section of the National Electric Light Association at the recent annual convention. Mr. Bigham was born in Grand Rapids, Ohio, on Sept. 10, 1877. He was educated at the Prima State Normal School. He was early employed in the construction department of the American Bridge Company at Pittsburgh, Pa., and later in the operating department of the American Sheet & Tin Plate Company. During the Spanish-American war he joined the army and served in the Philippines as sergeant in a volunteer regiment, and later as a sergeant-major. Mr. Bigham began electrical work with Stone & Webster in Terra Haute, Ind., in the Terre Haute Electric Company, in 1901. He later became assistant treasurer of the Paducah Light & Power Company, Paducah, Ky. In 1909 he became assistant treasurer of the Jacksonville (Fla.) Electric Company, and in 1910 became assistant treasurer of the Tampa Electric Company.

OBITUARY

James H. Van Dorn, president of the Van Dorn & Dutton Company and the Van Dorn Iron Works Company, Cleveland, Ohio, died suddenly at his home in that city on Aug. 29, as a result of an attack of heart trouble. He was seventy-three years of age. Mr. Van Dorn was born in York, Ohio. At eighteen years of age he was apprenticed to a blacksmith in Elyria, Ohio. Later he became an iron worker at Akron. In 1873 he went to Cleveland and laid the foundation of the companies that have since been developed into important industries. He is survived by a widow, two sons and three daughters.

Charles F. Baker, until six months ago connected with the Bay State Street Railway, Boston, Mass., as mechanical engineer in charge of power station construction, is dead. He had been with the company four years. Mr. Baker was long prominently identified with electric railway work. More than twenty years ago he was connected with the E. P. Allis Company, Milwaukee, Wis., engine builders, and had charge of the installation of the steam plant at the works of C. A. Pillsbury & Company, Minneapolis. In 1893 he entered the service of the West End Street Railway, Boston, now the Boston Elevated Railway. While with these companies Mr. Baker's titles were master mechanic and superintendent of motive power and machinery, and under his designs and supervision the East Boston, Charlestown, Dorchester and Howard power stations were built and the central power station was changed from a belt to a direct-connected plant. In 1905 Mr. Baker entered the service of the Brooklyn Rapid Transit Company as superintendent of power. Later he served as a member of the staff of Mr. Louis B. Stillwell at Baltimore and on the Hudson & Manhattan Railroad. Mr. Baker was a member of the American Society of Mechanical Engineers and the New England Street Railway Club, and in 1904 was elected president of the American Railway Mechanical & Electrical Association, the predecessor of the American Electric Railway Engineering Society.

The Hartford & Springfield Street Railway, recently announced a popular excursion to the base of Mount Tom, one of the most popular resorts in New England. The cars used on these trips are fifteen-bench open cars which under ordinary conditions carry six passengers to each seat. In order to assure patrons of more than ordinary comfort the capacity of each seat was limited to four. In announcing the excursion the company said: "No change of cars will be made from Hartford to Mountain Park, which is situated at the base of Mount Tom. From there the trip to the summit can be made at small expense by way of the inclined railway. Refreshments may be obtained either at Mountain Park at the base of Mount Tom or at the summit house on the mountain."

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Teal Creek Railway, Falls City, Ore.**—Incorporated to build a steam or electric railway from Falls City to a point in Polk County. Capital stock, $10,000. Incorporators: F. J. Cobbs, Zera Snow and Wallace McCamant.

FRANCHISES

Victoria, B. C.—The British Columbia Electric Railway Company, Ltd., has asked the Council for a franchise to double-track its line on Esquimalt Road between Dundas Street and Catherine Street. The company plans to build a double track on the entire line from Point Ellice Bridge to the terminal.

Pasadena, Cal.—The Pacific Electric Railway has applied to the City Commission for a 50-year franchise for a double track on North Lake Avenue.

Pocatello, Idaho.—Mayor Turner has vetoed the ordinance granting a franchise to J. D. Browning to operate a street railway in Pocatello.

Murphysboro, Ill.—The Murphysboro & Southern Illinois Railroad has applied to the Councils of Carbondale and Murphysboro for thirty-year franchises. Right-of-way has been offered across all but two pieces of property between the cities.

Neodesha, Kan.—On Sept. 8 citizens will vote on the proposal to grant a franchise to the Independence, Neodesha & Topeka Traction Company to build lines in and through Neodesha.

Holyoke, Mass.—The Holyoke Street Railway has received a revised franchise from the Board of Aldermen for double-tracking and extending its line in Aldenville.

TRACK AND ROADWAY

Lethbridge (Alta.) Municipal Railway.—A by-law is being advertised in Lethbridge which includes a clause to provide $13,153 for municipal electric railway extensions in that city.

Fort Smith Light & Traction Company, Fort Smith, Ark.—In a statement to the City Commissioners responding to complaints as to the progress of track work, the Fort Smith Light & Traction Company called attention to the fact that work now under way footed up $24,000, that the company had spent $71.000 in relaying tracks and preparing them for paving, and that the company would expend all the earnings over the interest charges in improvements; that no dividends had been paid on the common stock for three years and none on preferred stock for more than a year. The company expressed willingness to move its working force to such streets as might be designated.

Phoenix (Ariz.) Railway.—This company has asked the Corporation Commission for permission to build an extension to its Brill line.

Los Angeles, Cal.—The Pacific Electric Railway has filed an appeal to the City Council, asking that it be allowed to delay compliance with the orders of the Board of Public Works requiring the company to bring to street grade its tracks on several streets, until its application for a franchise for its two outside tracks on the four-track system of Long Beach Avenue is finally acted upon.

San Francisco, Cal.—The North Beach Promotion Association has filed with the Board of Supervisors a petition to extend the Stockton Street municipal line north along Stockton Street to the Embaracadero.

Waterbury-Milldale Tramway, Waterbury, Conn.—This company which is building an electric railway to connect Waterbury and Southington has nearly finished the erection of poles from the mountain top to Milldale. The grading for the roadbed is completed as far as Marion. The line will be 8½ miles long. Charles H. Clark, president.

***Liberty, Ind.**—The citizens of Liberty, Ind., and vicinity have been asked to contribute $60.000 toward the construction of an electric railway from Richmond, Ind., to Hamilton, Ohio. Union Township will give $20,000 and Center Township $40,000. The plan includes the extension of the line from Indianapolis to Connersville, connecting with the Richmond line east of Liberty with a station at Liberty.

Fort Scott & Pittsburg Interurban Railway, Fort Scott, Kan.—The first stock issue, $3,000, has been made by the Fort Scott Industrial Association, which has taken hold of the proposition and proposes to build the line between Fort Scott and Pittsburg.

Topeka (Kan.) Street Railway.—This company is laying new rails on Second Street and planning extensions of that line.

Bay State Street Railway, Boston, Mass.—The amusement resort of this company at Island Park was destroyed by fire on Aug. 25. The dance hall, bathing houses, shore dinner house and kitchens that comprise the company's main buildings were burned. A loss estimated at $10,000 is covered by insurance. It is stated that the company will rebuild the park next season.

Berkshire Street Railway, Pittsfield, Mass.—This company announces that it will lay 1300 ft. of 95-lb. T-rails on North Street from the end of the Wahconah Street work southerly, and will also replace tracks on East Street from Appleton Avenue to the court house.

Springfield (Mass.) Street Railway.—The Public Service Commission has issued three orders on the petition of the Springfield Street Railway for certificates preliminary to operation of sections of its railway in Springfield and Westfield. One order certifies that all laws have been complied with in the construction of a single-track connection in State and Hancock Streets. A similar certificate has been granted the company for a relocated turnout in Walnut Street. In Westfield the certificate granted to the company covers a section of railway consisting of a single-track extension in Franklin Street.

Battle Creek, Mich.—The Chamber of Commerce announces that J. T. Adams, contractor, will begin work at once on the interurban railway between Coldwater and Battle Creek. The Chamber of Commerce announced further that the financing was complete, but the names of several out-of-town men who helped swing the deal were not made public. The line will be 28 miles long and touch Beadle Lake, Newton, Lee Lake, Burlington, Girard, Morrison Lake and Coldwater, with a probable extension to Union City.

Kansas City (Mo.) Railways.—The board of control of this company met with the Board of Public Works of Kansas City last week, and approved plans for the changing of curves to reroute cars. and for reconstruction of tracks between Tenth and Twelfth Streets on Main Street.

***Atlantic City, N. J.**—William F. Wahl, Atlantic City, has proposed the construction of a high-speed electric railway along the western edge Inside Thoroughfare from Longport through Margate and Ventnor Heights to lower Chelsea and thence to a junction with the main line of the Pennsylvania Railroad on the meadows. In a proposition which Mr. Wahl will submit to the Pennsylvania Railroad on behalf of the residents of these resorts it will be pointed out that the motive power and rolling stock of the West Jersey & Seashore Railroad could be applied to the Longport extension.

***Riverside, N. J.**—Residents of Riverside, Riverview and Muhlenberg Park are interested in a plan to provide electric railway service between Riverside and Tuckerton. It is proposed to use the franchise granted several years ago on the Stoudt's Ferry Bridge Road. It is also planned to lease that portion of the Berks and Lehigh branch of the Reading Railway between Riverside and Muhlenburg Station. This section of track which is now used for storage purposes would be electrified. The formation of a company to finance the new line is planned.

Cincinnati, Indiana & Louisville Railway, Cincinnati, Ohio.—Engineers for this company are in the field making surveys for its roposed 85-mile gasoline-electric and steam railroad which is to connect Cincinnati, Lawrenceburg, Aurora, Rising Sun, Detroit, Patriot, Vevay and Madison. L. S. Cook, president. [E. R. J., March 21, '14.]

Glengarry & Stormont Railway, Cornwall, Ont.—This company, which plans to build a 27-mile railway between

St. Polycarpe and Cornwall, Ont., will operate the railway with steam and not by electricity. G. W. Farrell, Montreal, Que., president.

***Bridgeburg, Ont.**—The Hydro-Radial survey for an electric railway between Bridgeburg, Ont., and Dunnville, Ont., with a connecting line from Port Colborne to Welland, has been completed and J. N. Stanley, engineer in charge, and his staff are now engaged in preparing data for presentation to the Hydro-Electric Power Commission. The Bridgeburg-Dunnville line is about 39 miles long. It is about midway between the Grand Trunk's line and the shore of Lake Erie. Only two bridges will be necessary, one across the Welland Canal and the other across the feeder. The route from Port Colborne to Welland is about 8 miles in length and will follow the east side of the Welland canal to connect with the electric railway at present operated in Welland.

Baker, Ore.—Jacob Kreis, representing Portland capital, is projecting the construction of an electric railway to connect the city of Baker with the Panhandle section of the county.

Chattanooga Railway & Light Company, Chattanooga, Tenn.—The Vance Avenue extension of the Chattanooga Railway & Light Company is rapidly nearing completion. Rails have been laid for practically the whole distance and a large proportion of the ballasting is completed.

Nashville (Tenn.) Traction Company.—Work is rapidly progressing on the line of the Nashville Traction Company which will run from the northern boundary of the city to the city limits on Lafayette Street, and it is said that service can be begun on Nov. 1. The company has completed plans for extending the line out on the Murfreesboro pike to Una, but work will be delayed until the right-of-way recently granted by the County Court can be amended so as to give the line more territory. The Detroit-Nashville Construction Company is building the lines for the new company. It is said that current will be supplied from the plant at Hale's Bar.

Nashville Railway & Light Company, Nashville, Tenn.—The City Commission is to authorize the Nashville Railway & Light Company to lay double tracks along West End Avenue, from Twenty-first Avenue to the city limits, in accordance with the contract by which the railway company will share with the city the cost of condemnation proceedings and such reconstruction of the street as will be necessary.

Northern Texas Traction Company, Fort Worth, Tex.—This company has been asked to build an extension through Niles City to Diamond Hill. The company has decided to build a 1-mile extension to its Summit Avenue line in Fort Worth.

***Orange, Tex.**—J. C. Cox of Dallas is interested in a plan to construct a street railway in Orange.

Ogden (Utah) Rapid Transit Company.—This company has selected the route through Brigham City via Collinston and over the divide into Cache County for its Ogden-Preston extension, work on which is now said to be under way in Cache County. The engineers who have been engaged on the various surveys during the year have completed maps for the extension, and a moderately low grade has been established along the proposed route. The survey practically parallels the Oregon Short Line from Ogden to Collinston, taking a course just east of the Short Line's right-of-way. At a point just beyond Collinston the survey runs over the divide, eliminating the Bear River Canyon, and the proposed road will enter the towns of Wellsville and Hyrum, just south of the eastern end of the divide. Construction from this end will probably not commence until next spring, it is said.

Lynchburg Traction & Light Company, Lynchburg, Va.—This company contemplates extending its College Hill line out Fort Avenue at an early date. The terminus of the extension is to be opposite the Lynchburg Fort.

Tacoma Railway & Power Company, Tacoma, Wash.—Five street railway proposals have been placed before L. H. Bean, manager of the Tacoma Railway & Power Company by Mayor Fawcett. The extensions and changes proposed by the Mayor include the following: Extension of the Pacific Avenue line to South Sixty-fourth Street; extension of Center Street line; extension of Tacoma Avenue line so as to connect at present terminals with the Point Defiance and South Tacoma lines; extension of the K Street line to Twenty-sixth and Proctor Streets to meet the Point Defiance line; extension of Sixth Avenue line from southern terminals to Seventeenth Street and Pacific Avenue, in the city of Tacoma.

SHOPS AND BUILDINGS

Centralia & Central City Traction Company, Centralia, Ill.—This company is building a new station in Centralia. The building will also be used by the company for storing supplies.

Fort Wayne & Northern Indiana Traction Company, Fort Wayne, Ind.—It is announced that this company will build a large terminal station in Lafayette. The building will serve both as a station and for general offices.

Kansas City-Western Railway, Kansas City, Mo.—This company has under construction a new interurban depot at Lansing.

Rochester & Eastern Rapid Railway, Rochester, N. Y.—This company has completed plans for enlarging its station at Victor, N. Y.

Austin (Tex.) Street Railway.—This company has moved its offices from West Sixth Street to Congress Avenue, Austin. A clubroom has been fitted up for the use of the employees.

POWER HOUSES AND SUBSTATIONS

Illinois Central Traction Company, Peoria, Ill.—This company will place in operation two new General Electric 500-kw, 600-volt rotary converters with the necessary starting panels.

Chicago & Milwaukee Electric Railroad, Highwood, Ill.—This company will install in its North Chicago substation a 500-kw rotary converter, three 165-kva transformers, switchboard and accessories, which have been purchased from the General Electric Company.

Moncton (N. B.) Tramways, Electricity & Gas Company, Ltd.—This company is installing three 200-hp high-pressure boilers to replace four low-pressure boilers which have been used for several years.

New York Central & Hudson River Railroad, New York, N. Y.—Two new 2000-kw rotary converters and six 735-kva air-blast transformers and switchboards will be added to the substation equipment of this company. The contract to build and install the apparatus has been placed with the General Electric Company.

New York Municipal Railway, Brooklyn, N. Y.—This company has ordered from the General Electric Company three 4000-kw and three 2000-kw rotary converters, together with transformers and switchboard apparatus. The distribution of this apparatus among the various substations of the company will be as follows: Hudson Avenue substation, two 4000-kw rotary converters; Thirty-eighth Street substation, one 4000-kw converter; Utrecht Avenue substation, two 2000-kw converters; Coney Island substation, one 2000-kw converter.

Nashville Railway & Light Company, Nashville, Tenn.—It is reported that the Clark interests, which own the Nashville Railway & Light Company and the power plant at Ocoee, have contracted with the Brady interests for current from the power plant at Hale's Bar and that it is to be supplied to operate the local railway system. Transmission wires have been strung.

Virginia Railway & Power Company, Richmond, Va.—This company will add to its substation equipment two 400-kw, two-unit, three-bearing synchronous, frequency-changer sets, 14-kw and 17½-kw induction motor-generator sets and switchboards, this apparatus having been purchased from the General Electric Company.

Puget Sound Traction, Light & Power Company, Seattle, Wash.—This company will add to its substation equipment a 1000-kw motor-generator set with switchboard and accessories. The General Electric Company will supply the equipment.

Manufactures and Supplies

ROLLING STOCK

Kansas City (Mo.) Railways is reported to be constructing twenty-five new cars in its own shops.

Southern Traction & Power Company, Alexandria, La., is reported as expecting to purchase two new cars.

Parkersburg, Marietta & Interurban Railway, Parkersburg, W. Va., is reported to have ordered two all-steel interurban cars from the Cincinnati Car Company.

TRADE NOTES

Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has received from the Third Avenue Railway a repeat order covering twenty-five PK control equipments for use on its low floor 24-in. wheel cars.

Transportation Utilities Company, New York, N. Y., has opened an office at 1201 Virginia Railway & Power Building, Richmond, Va. This is now a regular branch office and devoted exclusively to the well-known appliances that are manufactured by this company. The Richmond office is in charge of Frank N. Grigg.

General Electric Company, Schenectady, N. Y., has received an order to equip with GE-200 double motor equipment, K 36 controllers and air-brake equipments the twelve interurban cars which were recently ordered by the Empire United Railways from the St. Louis Car Company.

Fred. B. Corey, formerly for eleven years in the engineering department of the General Electric Company, and for the past three years engineer of inspection and tests of the Union Switch & Signal Company, reporting to the general manager, has resigned that position and opened an office at 404 Arrott Building, Pittsburgh, Pa. He will conduct a consulting engineering business, making a specialty of inspection methods and organizations for manufacturing companies. He will also give attention to electric railway signaling and allied subjects.

Truman P. Gaylord, who has succeeded H. D. Shute as acting vice-president of the Westinghouse Electric & Manufacturing Company, was born at Shelby, Mich., and attended preparatory school at Allen Academy, Chicago. He subsequently attended the University of Michigan, and in 1895 received the degree of electrical engineer from the Armour Institute of Technology, Chicago. Mr. Gaylord was an engineer of underground construction during the World's Fair, at Chicago, in 1892-1893. At the close of the Fair he became assistant professor of electrical engineering in the Armour Institute, which position he retained until 1898 when he became associated with the Commonwealth Edison Company of Chicago as electrical engineer. In July, 1899, he entered the employ of the Westinghouse Electric & Manufacturing Company as a salesman, following this line of work until 1902, at which time he was appointed district manager of the company in Chicago, which position he held until his recent election as acting vice-president.

Henry D. Shute, who was recently elected treasurer of the Westinghouse Electric & Manufacturing Company, was born at Somerville, Mass. He attended high school in Boston, and was graduated from the Massachusetts Institute of Technology in 1892 with the degree of Bachelor of Science in Electrical Engineering. Following his graduation he spent a year in Germany at the School of Mines, Clausthal, and also in Dresden. In 1893 he entered the works of the Westinghouse Electric Company at Pittsburgh as an apprentice and spent his first two years in the testing department, following which he was engaged for a considerable time in erection and laboratory work under the direction of Charles F. Scott and Lewis B. Stillwell, and later as assistant foreman. He entered the engineering department in 1897. One year later he was transferred to the commercial department and in 1901 he was made head of the alternatiing current division of that department. Two years later he was promoted to the position of assistant to Vice-President L. A. Osborne, in which position he was particularly active in the development of the heavy electric traction and single-phase railway work. In 1910 Mr. Shute succeeded Walter McFarland as acting vice-president of the company, which position he held until his recent election as treasurer. Mr. Shute is a director of the Pittsburgh Chamber of Commerce, and is closely identified with a number of technical and social organizations.

ADVERTISING LITERATURE

Dielectric Manufacturing Company, St. Louis, Mo., has issued a folder on its wood preservative, phenoleum.

Ohio Brass Company, Mansfield, Ohio, has issued a folder entitled "A Question of Moment," on the subject of its rail bonds.

Joseph Dixon Crucible Company, Jersey City, N. J., has issued a guide to useful Spanish words and phrases, compiled for the use of tourists and travelers.

William J. Niles, Philadelphia, Pa., manufacturer of flake white cement paint and specialist in the coating of concrete buildings, has issued a folder illustrating the work done in coating the Barcley Building, Newark, N. J.

Nachod Signal Company, Inc., New York, N. Y., has issued a leaflet describing the Philadelphia (Pa.) Rapid Transit Company's installation of trolley contact signals on its Chester Short Line, showing the signaling layout and car movements.

National Tube Company, Pittsburgh, Pa., has issued a catalog describing its regrinding valves. Three illustrations show a valve which was opened and closed 327,094 times. After being reground several times this valve was opened and closed over 3,046,280 times and is still in use.

Chicago Pneumatic Tool Company, Chicago, Ill., has issued a bulletin describing its Ruby all-steel sectional buildings for railroad purposes. The special uses to which these buildings are applied include hand-car and tool houses, storehouses, warehouses and interurban shelter stations.

De La Vergne Machine Company, Mott Sand Blast Department, New York, N. Y., has issued a reprint of a paper recently read before the Associated Foundry Foremen of New York and Vicinity by H. D. Gates, sales manager, sand blast department of this company, which gives practical points on the selection and operation of sand blast equipment.

Stewart Warner Speedometer Corporation, Chicago, Ill, has issued a catalog describing its railway meters adapted for use in interurban railway cars and in school cars for training motormen how to operate cars at correct speeds in order to run them on time, also how to economize on power, An illustration in the catalog, accompanied by a letter, shows this latter application, as practiced in a school trolley car of the Toronto (Ont.) Railway.

Cutler Hammer Manufacturing Company, Milwaukee, Wis., has issued a series of bulletins for July, 1914, of which Nos. 4500, 4510, 4520 and 4530 describe its new line of automatic machine tool controllers for use with shunt or compound-wound d.c. motors, adapted for constant or adjustable speed work, with or without interpoles. Increased output and lower cost of production is claimed for this automatic control owing to the ability of the operator to start and stop without leaving his normal position; the possibility of the foreman setting the control at the proper speed for a job and leaving the operator free to start and stop, but unable to change speed; and the dynamic brake, by which a tool that would otherwise run several seconds after the power is cut off, is brought to rest practically at once by the motor, which acts as a generator and stops the tool. Bulletin No. 4510 describes automatic machine tool controllers of the plain starting type; Bulletin No. 4520, those of the speed setting type, and Bulletin No. 4530, those of the speed regulating type. Bulletin No. 6753 describes double-pole diaphragm regulators for d.c. and a.c. motors; Bulletin No. 7131, full magnetic controllers; Bulletin No. 9125, secondary resistance starting rheostats for polyphase slip ring motors; Bulletin No. 9130, multiple-switch starters; Bulletin No. 9135, drum type starters; Bulletin No. 9155, drum reverse switches; Bulletin No. 9320, panel type speed regulators; Bulletin No. 9350, drum reversible crane controllers; Bulletin No. 9355, hoist controllers; Bulletin No. 9359, rope operated drum reverse switch; Bulletins Nos. 9360 and 9365, speed regulators.

Consolidation of STREET RAILWAY JOURNAL AND ELECTRIC RAILWAY REVIEW

Vol. XLIV NEW YORK, SATURDAY, SEPTEMBER 12, 1914 No. 11

HARD TIMES AND THE CONVENTION

Expenditures are being scrutinized this year with unusual care. The expense of sending delegates to Atlantic City will necessarily come up for review, and there may be a tendency to cut down at this point. It is to be hoped that this tendency will be resisted, for the industry needs the convention more this year than ever. The necessity for care in expenditure will have the advantage of enforcing the choice of the best-equipped men as delegates. It must be remembered that the convention is still the most vital thing in the Association. Once it was the whole thing, but now we have the elaborate machinery of the secretary's office, the effective midwinter meeting and the continuous grind of committee activity. The success of the association, however, is still bound up in that of the convention, and its increasing size demonstrates that this fact is appreciated. The exhibits this year will be at least as extensive as ever, an excellent program has been prepared, and there is every reason to expect a more than usually fine convention.

SINGLE-LINE WIRING DIAGRAMS

At the risk of repetition, we desire to emphasize the great value of single-line wiring diagrams in studying the operating features of generating plants, transmission and distribution systems. Continued observation of the usefulness of such sketches, whether made by free-hand or instrumental methods, justifies the opinion that the electric service or railway company which does not employ these simple aids to convenient operation when using alternating current is suffering from a severe case of executive mental friction in the technical department. One is almost inclined to assert that without such diagrams it is scarcely feasible to operate a high-tension system with due regard to safety and reliability of service; but the value of the single-line wiring layout applies to the distribution system as well. It would be hard to find any branch of engineering in which symbols of standard types of apparatus save more time than in applied electricity, and there is no easier way of taking into one's mind the essentials of the electrical arrangements in a modern plant, transmission system or substation than through the combination of such symbols with single-line connections. Such drawings are, of course, merely skeletons of plant arrangement, but they can be prepared in a few moments even for a fairly complex installation, including every essential switch, busbar, transformer coil and feeder type. The space occupied by such a sketch is trifling and admirably adapted to cards and loose leaves; auxiliary connections associated with measurement and automatic control of circuits are omitted without the slightest sacrifice of convenience. The bird's-eye comprehension of the system thus afforded is of the utmost value.

STEEL SHEATHING FOR CAR SIDING

It is interesting to note from the communication by F. R. Phillips, published elsewhere in this issue, that the standard thickness of side sheathing used on the Pittsburgh steel cars has been reduced recently to that of No. 14 gage sheet metal. This is halfway between the more commonly used thickness of 3/32 in. and the minimum, which, so far as we know, is 1/16 in. It is also interesting to note that this thickness of sheet with a flat bar for a belt rail and an angle for a side sill was found by Mr. Phillips to be more than sufficient to carry the load imposed by the weight of the car. This evidence in support of the use of the car siding to carry weight in place of the cumbrous center and side sills required in the underframe type of design is cumulative in character, but it is none the less valuable in pointing out the reason why the steel or semi-steel car is infinitely preferable with regard to weight and strength to one that is built of wood. The latter may, of course, be built in accordance with the principles of the side-girder design, such a construction having been reported as used many years ago on some cars for the old Atlantic Coast Electric Railway. However, the complication of the construction in wood was enormous in comparison to that required now that steel is available, and it is not surprising that the basis of the arguments on steel versus wood has centered on the relative merits of the side-girder truss construction as opposed to the underframe. It is this fact largely which makes the outlook so hopeless for the wooden car.

TRAIN RESISTANCE FORMULAS

In a communication printed in a recent issue of the ELECTRIC RAILWAY JOURNAL D. D. Ewing stated that he feared "that we shall have as much trouble in learning how to measure train resistance by direct measurement as we have had in deriving the 'generalized' formula for train resistance which C. O. Mailloux so 'devoutly' wishes for." Professor Ewing exhibited some curves showing that tests made on different cars within the past year yield data so different that they are applicable to other cases only under the conditions of the tests from which they were derived. In spite of the large expenditures made to secure facts of general application we seem to be little farther along in this direction than we were ten years ago. The data accumulated by temporary scientific organizations such as the Studiengesellschaft für Schnellbahnen and the St. Louis Electric Railway Test Commission seem not to have been utilized as they might. The former made many measurements of the resistance to the motion of models of car fronts through the air at all speeds besides investigating conditions of pressure, power consumption, etc., in large, specially built cars driven up to enormous speeds. The latter hung actual car vestibules on frictionless supports and drove them at various speeds, measuring the air pressure by means of dynamometers. Many other less extensive tests have been made and reported from time to time. Most of these experiments dealt with air resistance because this was considered most to need investigation. But the friction of journals, flanges, etc., has been under investigation also and much information along this line is available in other fields. With all of it at hand it would seem that a rational formula should be in sight. There has been a lull in activity in this subject for a few years. Possibly it is time to take it up again with renewed interest.

BROKEN BOLTS IN BUILT-UP CROSSINGS

Engineers for both electric and steam roads are constantly confronted with the problem of the best method of reducing the number of broken bolts in built-up railroad crossings. The usual plan is to reduce the vibration from traffic to a minimum by the installation of especially heavy timber sleepers to support the crossing on a ballast foundation, which usually is of extra depth. Many engineers have also increased the size of the bolts as a means of reducing this incessant breakage. Unquestionably the treated bolts which have recently come into general use have materially reduced the problem of broken bolts at crossings, but even with untreated bolts a number of steps may be taken to reduce materially the percentage of breakage.

Undoubtedly the broken bolt is the result of an unequal distribution of the load over all the bolts in a crossing. It is a well-known fact that ordinary track bolts stretch, and as soon as this has occurred the load is shifted from the loose bolt to a tight one which cannot carry a double load and breaks in a short time. If all the bolts are kept uniformly tight in a crossing, breakage will be reduced to a minimum. This means constant attention, and in any crossing all nuts should be provided with locking devices which will resist vibration.

If locking devices are used one cause of bolt breakage will be removed, and if followed by systematic and frequent tightening of the nuts, the second cause for trouble will disappear. Even with the treated bolt in a built-up crossing a lock device of some character should be employed so as to insure maximum life from the rails which form the composite crossing structure. All rails, namely, the running, easer and guard rails, must assume their portion of the load if maximum life in service is to be attained.

STANDARDIZATION IN CAR DESIGN

In any branch of any industry the possibilities of standardization are limited only by the industry's needs. The opportunities for economy, not only in first cost but in repairs as well, which are made available by standard design are of literally enormous scope. Ford, turning out complete automobiles at a manufacturing cost of some $200 each and providing repair parts in every hamlet throughout the country, is a living example of what strict standardization can accomplish. Although this case is an extreme one, it is only so because the needs of the automobile industry make it peculiarly susceptible to the advantages of the single design.

That the same conditions do not exist in the street railway industry may be accounted for largely by the less need for it in the past. A single design of car in universal use would, no doubt, have effected considerable savings during the last few years, although balanced against this would have been the loss of the experience gained by innumerable experiments together with the limitations, often exaggerated perhaps, that are imposed by the different physical conditions existing in different cities. However, the main reason for the present complete absence of standards in car design must be ascribed mainly to the fact that the need for them has by no means been a crying one. Electric railway cars, until a very short time ago, were universally built of wood, and on account of the ease and flexibility with which this material can be worked a change in design has meant but very little added expense.

With wooden cars it has been almost literally true that when an order for a car was received the builder sent out to the lumber storage and had it whittled out without waiting for detailed drawings. Under such circumstances it is hardly extraordinary that no exact standards have been developed. However, these conditions are now beginning to change. The all-steel car has made its appearance in both city and interurban service, and it is unquestionably going to stay. Indeed the steadily diminishing supply of wood makes the universal use of steel only a question of time, even neglecting its present inherent advantages.

This new factor in car construction cannot fail to change the viewpoint of the industry in regard to standard car design. The steel car cannot be whittled out like a wooden one. Dies, jigs and templets are required everywhere in its construction, and even the raw material from the steel mill is too costly to be maintained in large stocks by the builders. Standardization in car design has, therefore, suddenly become a need of the electric railway industry. That this need will grow with time cannot be doubted, and the premium placed upon uniformity in design will soon be too great to be neglected.

How far standardization can be carried in the near future is, of course, a moot question. The adoption of uniform dimensions for width and length is, perhaps, an impossibility, but there are numerous other features in design which need little more than official action for their standardization. This has been shown by the replies of a number of railways to letters sent by the ELECTRIC RAILWAY JOURNAL in regard to their practice in establishing certain dimensions, the information thus far received showing that some approximate standards actually exist to-day, although these have been adopted unconsciously and in accordance with the dictates of experience rather than through a desire for uniformity in design.

Certain roads have, of course, established standards of their own, and to the extent of reducing repair costs, these are of undoubted value. What is needed, however, is the standard of general application, and it is probable that the individual or local standards will prove rather a hindrance than a help. Be that as it may, if full benefits are to be obtained from the use of the steel car, many universal standards must eventually be fixed. This issue cannot be avoided, and it might better be faced now than several years hence, when the steel car has passed its infancy and is, in consequence, much less subject to modification than it is at present.

MAKING THE MOST OF THE CONVENTION

Advance copies of the A. E. R. A. committee reports will be sent out to members in a few days with a view to stimulating intelligent interest in the discussion. We take pleasure in responding to Secretary Burritt's suggestion that we urge advance study of these preprints, especially by those who expect to attend the convention. The expense to the association in publishing these reports is very great, and strenuous work on the part of committees has been necessary to complete them early. It is therefore highly desirable that the best possible use be made of them. Each year it becomes more important for the individual members of the American and allied associations to do some study preliminary to the conventions. Electric railroading is increasingly complicated, for development on the technical side is very rapid, while the public expects more and expects it cheaper. The association and its conventions must take a more vital grip on the industry and must be a source of information and inspiration to all concerned.

With the publication of these reports the association has done its part of the work. It is now up to the companies and the men whom they send to make the conventions a success or a failure. Success means that the companies must send their best men, and that these men must go prepared to discuss the papers and reports. Every company planning to send delegates, therefore, should insist that the contents of the reports be mastered at once. In this connection it is our belief that the comparatively inexperienced man who prepares himself thoroughly on one or more fundamental topics will do more for the convention and get more out of it than the more experienced one who depends upon the inspiration of the moment.

There is another advantage in such a preparation as we have mentioned. It safeguards the interests of the industry by insuring close scrutiny of committee reports. Conventions are too apt to accept and adopt committee reports because the committees are made up of good fellows, who ought to know their business, and each attendant feels that he is not as well qualified to discuss the subjects at issue.

Advance distribution of reports is intended to prevent this and will do so if the reports are studied. Proper use of preprints, then, benefits the industry, the association and the individual. There is no danger of becoming one of the "bump-on-the-log" type if one is studying in this way.

THE REVIVAL OF THE FLAGGING RULE

Elsewhere in this issue appears a communication by John Leisenring on the subject of the erstwhile rule which, at one time, permitted a train to proceed when protected by a flag in advance. Mr. Leisenring's experience in the electric railway field and his prominence in committee work naturally lend a great deal of weight to his opinion on this question which, summed up, is that, since present practice prohibits a train from accepting a clear signal as superior to the time-card it should logically refuse to accept a stop signal except as a warning when the indication could not possibly be produced by any scheduled train.

Mr. Leisenring's point is well taken when it is confined to consideration of normal operation, but there is one objection to his argument which we might raise at this time. This is the fact that motormen, and even dispatchers, sometimes make mistakes. If they did not, there would be no need for signals as now used. The delayed train, meeting an unexpected stop signal, as in the case cited by Mr. Leisenring, has, in the first place, no means of knowing that no one in advance has made a mistake. Even after waiting for a period long enough to permit any train to get through the block in advance (and this is something not always provided in the rule books) the delayed train has no surety that an opposing train has not entered the block, contrary to rules, while the wait was being made.

All of this, of course, assumes perfect observance of the old flagging rule, but, as a matter of fact, we all know that, in practice, its provisions are very carelessly followed. When signals are installed the permission to proceed past a stop indication under the doubtful protection of a flag can lead to nothing but disrespect for the importance of the horizontal semaphore arm and red light, and it is just this that causes most of the accidents in signalled territory. Indeed, if it is going to be necessary for railroads to fall back upon the time-card and standard code when the signals do anything more than present the most stilted and obvious indications, it is likely that the trainmen will cease to regard them as anything more than a joke. It is to provide for the extraordinary condition, the error in judgment or action, that signals are most often considered necessary. Signal rules might better support this well-established doctrine than to render it negative for the sake of saving a little time when signal failures occur.

The Chicago and West Towns Railway

Operating and Engineering Features of a City and Suburban Railway in a Densely Populated District West of Chicago—The Line Has Recently Been Rehabilitated for Efficient Operation

The beginning of what now forms the Chicago & West Towns Railway System, containing approximately 75 miles of track, was the natural growth in the surface railway lines extending beyond the corporate limits of Chicago, Ill. The original properties were the Cicero & Proviso Street Railway and the Ogden Street Railway, which later were operated by the Chicago Consolidated Traction Company. These companies passed through several consolidations and reorganizations until, in 1910, three years after the city of Chicago had granted new ordinances to the Chicago Railways, of which a portion of these lines was a part, a decree was entered by the United States Supreme Court ordering the sale of that portion of the lines outside the Chicago city limits. These lines were then purchased by the County Traction Company. In July, 1913, the County Traction and the Suburban Railroad were taken over by the Chicago & West Towns Railway and are now operated as a unified property.

TERRITORY SERVED

The following are the principal cities and towns served: Oak Park, River Forest, Maywood, Melrose Park, Forest Park, Cicero, Berwyn, Lyons, Riverside, Brookfield and LaGrange. Within recent years this territory has grown rapidly and now has become densely populated. It covers an area of approximately 35 square miles, and is served by five main east and west lines of the Chicago & West Towns Railway. One of these is known as the suburban line and extends from the corporate limits of Chicago to LaGrange, Ill.

In all these five lines traverse seventeen different cities made up largely of two classes of people, namely, those who travel into the city of Chicago in the morning and out at night and those who work in the factories located in this territory. Both classes of passengers tend to develop an abnormal morning and evening peak. A relatively good average load factor is obtained, however, because of the midday traffic to and from several large cemeteries located directly on the routes of this road. Also, during the summer months, many picnics and outing parties are carried to the summer parks and groves located on this company's lines in the territory along the Desplaines River.

RATES OF FARE

For a number of years a single 5-cent rate was charged over this company's entire system. Recently, however, the fare on the "suburban" line was increased to a maximum of 10 cents. At an intermediate point, namely, the east boundary line of Riverside, a 5-cent fare limit has been established. To regular riders beyond this point, however, several forms of commutation tickets have been issued. These are furnished as ten rides for 90 cents, twenty-five rides for $2, and sixty-ride monthly individual tickets for $3. In order to provide for those passengers living between the end of the line and this 5-cent fare limit, a 7-cent single fare is charged from points midway between the 5-cent far limit and the end of the line. Commutation rates are also available to regular riders from the intermediate points, the lowest individual commutation fare being 5 cents. A map of the system is shown herewith.

TRACK STANDARDS

Within the past two years practically all of the track in paved streets has been rehabilitated. The standard type of track construction used in this work included a 96-lb. 7-in. girder-grooved rail in 60-ft. lengths. This was laid on 5-in. x 7-in. x 7-ft. white oak ties on a 6-in. rolled crushed-stone foundation. Surmounting this is a 7-in. concrete base for the pavement foundation, a 1-in. sand cushion and the brick paving surface. The irregular section formed by the rail is squared by plastering grout on each side, between the base and the head of

the rail, thus insuring a water-tight joint where the paving joins the rail. Sixty-foot rail lengths were used to reduce the number of joints and they are made of 26-in. channels with six bolts. Track bonding is of the exposed type, being formed of one No. 0000 solid wire bond, 32 in. long and with compressed terminals.

On the "suburban" line, in unpaved streets and in the private right-of-way, the standard track construction consists of 7-in. 70-lb. T-rail laid on 6-in. x 8-in. x 8-ft. cedar ties spaced at 2-ft. centers. The track foundation under this class of construction is exactly like that in city paved streets; that is, it consists of 6 in. of rolled crushed-stone ballast. This is brought up to the level of the tops of the ties, and cinders are used to make up the road surface, which is leveled off even with the tops of the rails. The rails are fitted with round tie rods at 7-ft. 6-in. intervals, and are provided with four-hole 22-in. channel-plate joints. This class of construction also includes 60-ft. rail lengths and two types of bonds, namely, a No. 0000 8-in. brazed bond or two No. 00 expanded terminal bonds.

Two classes of special work were used in the standard types of track construction, namely, a built-up T-rail construction for frogs and crossings on the "suburban" line and at points in unpaved streets, and the cast-iron bond manganese insert construction in paved streets. Most of the lines are laid as double track with a standard track spacing of 9 ft. 8 in. between centers. One type of track construction is shown in cross-section in an accompanying illustration.

BRIDGES AND STRUCTURES

As indicated on the accompanying map of this company's lines, a number of important bridges and trestles were necessary where the lines cross the Desplaines River and Salt Creek. These include five structures, two of which are reinforced concrete arches built under contract with the cities. Each of the latter structures provides a wide walkway and roadway, and the one known as the Madison Street bridge in River Forest carries a single track while the other concrete structure, known as the Lake Street bridge, in Maywood, provides for paved driveways and walkways and a double track. On the line extending into Lyons, the track crosses the Desplaines River on a combination steel and wooden bridge used exclusively by the railway company but provided with walkways for the convenience of picnic parties, which are carried to this point during the summer months.

POWER GENERATION AND DISTRIBUTION

At the present time the Chicago & West Towns Railway owns two generating stations, one in Oak Park, known as the West Lake Street and Harvey Avenue station, and another as the Harlem Avenue and West Twenty-second Street station. The generating units at the Lake Street and Harvey Avenue station include two 465-kw and two 750-kw Siemens-Halske d.c. generators. These are driven by two 26-in. x 40-in. x 48-in. cross-compound Corliss engines, one 24-in. x 38-in. x 60-in. compound Corliss engine and one 28-in. x 48-in. simple Bullock engine. The tandem compound Corliss engine is direct connected to the two 465-kw generators. The cross-compound engine is direct connected to the two 750-kw units, which are generally used to take care of a railway power demand, the outer unit serving as spare. The generator and engine room is served by a 25-ton 55-ft. electric crane mounted on a runway which extends the full length of the building.

The boiler equipment consists of eight 300-hp Campbell & Zell water-tube boilers with Murphy automatic stokers and smokeless furnaces. These are served by a 200-ft. octagonal brick stack, 12 ft. in diameter. Coal

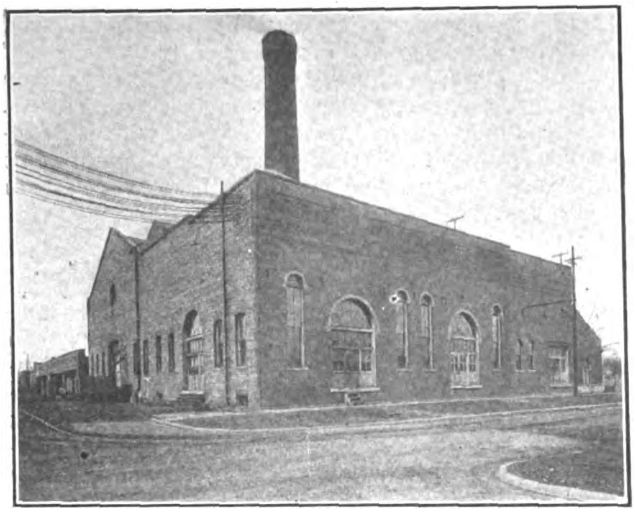
CHICAGO & WEST TOWNS RAILWAY—STANDARD CITY CAR



CHICAGO & WEST TOWNS RAILWAY—POWER STATIONS AT LAKE STREET AND HARLEM AVENUE

is supplied from overhead steel bunkers, which in turn are charged by a combination bucket and belt conveying system. Coal is dumped into a track hopper outside the power station, where, if necessary, it is passed through crushers to the conveying system. Boiler feedwater is supplied by a Worthington vertical duplex pump and two Blake vertical duplex pumps. From these the make-up water passes through a Cochrane feedwater heater and purifier of 500-hp capacity.

The overhead steel bunkers over the boiler-room aisle have a fuel storage capacity of 150 tons, and a storage shed in the yard adjoining the station building provides additional capacity for 550 tons of coal. The coal conveying system also serves for handling ashes, which may be delivered direct to cars on the street railway company's tracks beside the power station.

An unusually good load factor is obtained at this station, both for the average week-day and average Sunday loads, which is an evidence of the regular and continuous movement of traffic from 7 o'clock in the morning until about 8 o'clock in the evening. The average load during Sunday is somewhat unusual, reaching approximately 1300 kw at 1.30 p.m. and continuing at that point until about 9.30 in the evening. The average daily output is approximately 22,500 kw-hr.

The power-plant equipment at the Harlem Avenue and West Twenty-second Street station consists of two Walker generators of 750-kw capacity, direct connected to two Greene tandem engines. The boiler equipment consists of three 300-hp Sterling boilers served by a steel smokestack with a brick base, having a total height of 145 ft. There is also a condensing system lagoon built of concrete, the area of which is 21,109 sq. ft.

ROLLING STOCK

The rolling stock of this company includes eighty-four cars of the following types: twenty-one double-truck interurban motor cars, twenty-four double-truck city motor cars, sixteen double-truck trail cars and twenty-three general utility cars. The interurban cars operate over the suburban line from the Chicago city limits to LaGrange. They have double-end, closed monitor-roof bodies, 44 ft. 6 in. long by 8 ft. 8 in. wide, arranged for a seating capacity of forty-eight passengers. The interior finish is cherry and the cars are fitted with twelve drop sashes on each side. The car bodies are mounted on McGuire-Cummings trucks with a 6-ft. 6-in. wheelbase and are equipped with four GE-203 motors and type MK control. During the rush-hour periods these motor cars haul trail cars of a similar design, which have seating capacity for thirty-six passengers.

The standard city motor cars have closed arched-roof bodies, 45 ft. 6 in. long by 8 ft. 6 in. wide. They are of semi-steel construction and designed with eleven drop sashes on each side. The interior finish of these cars is cherry. They have reversible rattan seats for forty-four passengers. These cars were built by the McGuire-Cummings Manufacturing Company. Four-

teen of them are equipped with four GE-226 motors with K-35 control, and ten cars are equipped with two GE-203 form-L motors with K-51 control.

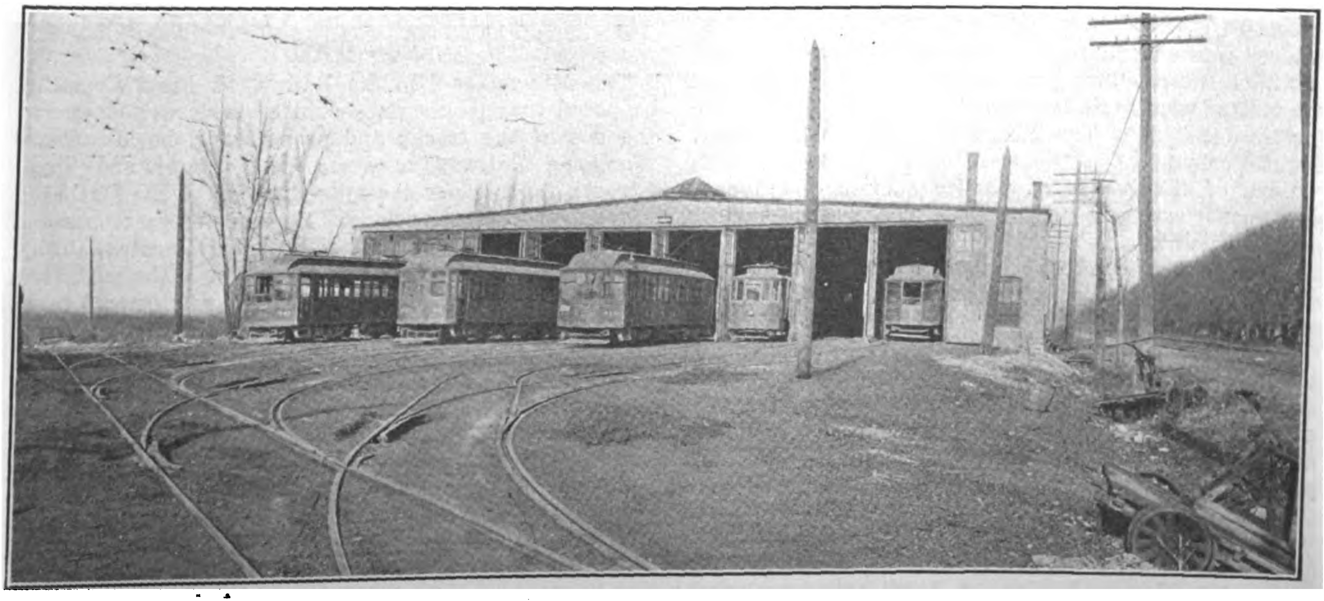
CAR STATIONS, SHOPS AND OFFICE BUILDING

Located at West Lake Street and Cuyler Avenue in Oak Park is a combination car station, repair shop and office building. This is a pressed-brick and steel structure, 192 ft. x 227 ft. 7 in. in plan, the office portion of which is two stories in height. This building occupies an entire block. The entrance to the office building leads from West Lake Street. Entrances to the carhouse and repair shops are from a ladder track on North Boulevard. Three tracks enter the repair shop, in which two of them pass over 180-ft. concrete inspection pits extending approximately the full length of the shop. These three tracks occupy about one-half of the floor space, the other half being equipped with repair-shop machines installed with individual motor drive. The repair shop joins the two-story office building on the rear. Connected to these is a one-story brick and steel carhouse with eight single-track bays. A brick partition wall with fire doors separates the repair shop and carhouse. The bays in the carhouse are separated by hollow-tile partition walls, also fitted with fire doors. All car entrances are provided with Kinnear rolling doors manually operated.

A second carhouse and repair shop for interurban cars is situated on the same property with the Harlem Avenue generating station. This is a brick and steel structure 115 ft. wide by 225 ft. long. As shown in one of the illustrations, nine tracks enter one end of this building through double swinging doors. These tracks lead from a single ladder track located at a sufficient distance from the building entrances to provide clearance for at least one car in the open. Light repairs are made at this carhouse, and it also serves as headquarters for the train crews for the suburban line.

OPERATING ORGANIZATION

The personnel of the executive and operating organization and heads of departments is as follows: Willard H. McEwen, president; Frank L. Butler, general manager; Charles F. Propst, secretary; John Whitsell, superintendent of transportation; W. C. Bell, assistant superintendent of transportation; Bert C. Collette, claim agent; William Armstrong, auditor; Orville C. Badger, engineer maintenance of way; P. S. Woodward, master mechanic; H. R. Chadwick, superintendent of overhead; B. F. Nickerson, roadmaster, and J. A. Olson, chief engineer of power stations. The attention of the operating officials during the past year has been directed largely to the rehabilitation of the property. It has been modernized and rebuilt for efficient operation. Plans are now being made for various extensions that have become necessary because of the growth of the territory.



CHICAGO & WEST TOWNS RAILWAY—GENERAL VIEW OF HARLEM AVENUE CARHOUSE

Joint Use of Tracks in Milwaukee

Decisions in Cases of Milwaukee Electric Light & Railway Company Versus Milwaukee Northern Railway and Versus the Chicago & Milwaukee Electric Railway—Railroad Commission Settles Questions Regarding Liability for Damages, Right to Furnish Power and Compensation for Power and Use of Tracks and Equipment

Two decisions on joint use of tracks have been rendered by the Railroad Commission of Wisconsin in the cases of The Milwaukee Electric Railway & Light Company versus the Milwaukee Northern Railway and versus the Chicago & Milwaukee Electric Railway. The Milwaukee Electric Railway & Light Company owns practically all the lines in Milwaukee, and each of the other companies operates an interurban line, one from the north and the other from the south, over single streets and along its own tracks to about the center of the city. The cases involved the right of the city company to improve traffic conditions by operating its cars over certain portions of the tracks of the other two companies within the city limits, as well as the placing of the liability for accidents and the determining of the right to furnish power and the compensation for the use of track, power, etc.

MILWAUKEE NORTHERN RAILWAY

The section in question in the case of the Milwaukee Northern Railway lies between Fifth and Sixth Streets. The company operates under the authority of an ordinance passed on March 22, 1906, which provides among other things that the city reserves the right to grant permission to use the company's tracks and motive power on payment of a just and adequate compensation by other lines in the city. Acting under the rights reserved in this ordinance, the city on April 14, 1913, passed an ordinance permitting The Milwaukee Electric Railway & Light Company to extend its tracks on Wells Street from West Water Street to Fifth Street and from Sixth Street to Eleventh Street. This move was taken because of the congestion of traffic on the tracks of The Milwaukee Electric Railway & Light Company and the possibility of re-routing some of its lines in case the new line was built. It was provided that the tracks should be completed within six months and that The Milwaukee Electric Railway & Light Company should receive permission, subject to the prior and preferential rights of the Milwaukee Northern Railway, to the latter's tracks and other equipment on Wells Street between Fifth and Sixth Streets. The two companies entered into negotiations looking toward an agreement, but upon their failure to meet upon the terms involved the matter was carried before the Railroad Commission for its decision by The Milwaukee Electric Railway & Light Company.

Each of the interested parties submitted a formal agreement embodying its ideas concerning various points which it considered ought to be covered. Most of these were in substantial accord and no mention was made of them in the commission's decision. In the matter of liability for accidents and compensation for the furnishing of power and the use of tracks and equipment, however, the two companies did not agree; and, after stating that public necessity and convenience demanded the joint use of the tracks, the commission devoted most of its decision to a discussion of these points.

LIABILITY FOR ACCIDENTS

The Milwaukee Northern Railway proposed that The Milwaukee Electric Railway & Light Company should indemnify it for all liabilities and claims growing directly or indirectly out of the operation of cars or equipment owned by the latter company over the tracks on Wells Street between Fifth and Sixth Streets, the intention being to place on the latter company all liability, whether accidents were due to acts of its own employees or officials, to acts of the employees or officials of both companies or even to acts of the employees or officials of the Milwaukee Northern Railway alone. This view was taken on the ground that the joint use of these tracks would mean increased risk and that the compensation which the Milwaukee Northern Railway would receive for the use of the property would be comparatively small. The commission stated that it realized that the earnings from this source for a period of years might be wiped out by the losses due to a single accident, but that this was not sufficient reason for taking all the burden of responsibility for accidents from the Milwaukee Northern Railway and placing it upon the other company. According to the commission, the joint use of the tracks was something that was being forced in a measure upon both companies for the benefit of the public and no reason existed for discriminating between them.

The commission decided, therefore, that the Milwaukee Northern Railway must indemnify the city company for any loss or damages which the latter may sustain to its property by reason of the operation of cars or equipment of the Milwaukee Northern Railway or any cars operated in its custody, and vice versa. In the case of the damage being caused by the fault or negligence of both companies, each company must bear one-half of the loss, excepting attorneys' fees. When any claim is brought against one company based solely upon the operation of the other company's cars, the first company shall notify the latter company and the latter must at its own expense settle the claim or defend any action brought. In the case of a joint liability, each company must notify the other in order to give it the right to appear and participate in the action.

COMPENSATION FOR USE OF TRACK AND OVERHEAD EQUIPMENT

The Milwaukee Electric Railway & Light Company proposed that payments should be made as follows for the use of the tracks and property of the Milwaukee Northern Railway between Fifth Street and Sixth Street: 6 cents per car mile for each of the first 5000 car miles or fractional part thereof per year operated over this section by The Milwaukee Electric Railway & Light Company; 4½ cents for each of the next 5000 car miles or fractional part thereof per year; 3 cents for each of the next 5000 car miles or fractional part thereof per year, and 2½ cents for each car mile or fractional part thereof over 15,000 car miles per year. According to the exhibit presented by The Milwaukee Electric Railway & Light Company, as based on its own experience, the maintenance and operating cost per car mile would amount to 1.08 cents. The fixed charges, estimated as a percentage of the investment, would amount to 7.60 per cent for depreciation, 1.97 per cent for taxes and 7.50 per cent for return on the investment, giving the total fixed charges of 17.07 per cent. On a basis of an aggregate investment of $38,559 per mile of single track, the fixed charge would amount to $6,582 per year. Then, by assuming various annual car miles per mile of track, the rental was shown to vary as follows: From 1.08 cents for operating expenses per car mile and 6.58 cents for fixed charges per car mile, or a total of 7.66 cents, in the case of 100,000 car miles to 1.08 cents for operating expenses per car mile and 2.19 cents fixed charges per car mile, a total of 3.27 cents, in the case of 300,000 car miles per year. This last figure was supposed to be the maximum that could be operated to advantage on a single track. In arriving at the sliding scale of compensation proposed, the aim of The Milwaukee Electric Railway & Light Company was to get an average rate of 4 cents per car mile.

It was found by the commission, however, that under the sliding scale the compensation paid by The Milwaukee Electric Railway & Light Company would not always be adequate, and there appeared to be no condition under which each company would bear a share of the burden exactly proportionate to the use of the tracks. In the opinion of the commission the proper basis for such compensation would involve the consideration of the cost of maintaining the property in good repair, net cost of renewals, replacements and reconstruction, taxes paid upon the property and a reasonable rate of return.

On account of the fact that the items mentioned vary for different railways and even for different sections of the same railway, the commission deemed it better to determine the actual cost so far as possible on the particular piece of property in question rather than the average cost for the entire system. The proposal of The Milwaukee Electric Railway & Light Company was held to be open to the objection that a portion of the figures used represented the average cost of its own property instead of the actual cost on the property of the other company. Furthermore, the use of car miles as a unit would not give a just division, since the types of cars used by the two companies might vary considerably in weight and capacity.

DETERMINATION OF TON MILEAGE

For the above reasons the commission decided upon an exact accounting of cost on the property in question and upon a division of the cost upon a ton-mile basis about in accordance with the plan proposed by the Milwaukee Northern Railway. This company proposed that the ton miles operated should be computed upon a basis of the total number of tons of 2000 lb. passing over the tracks, except that in the case of passenger cars the weight of passengers, merchandise and express matter should be excluded from the tonnage. The Milwaukee Electric Railway & Light Company's proposal was similar, but it provided that in the case of all cars used exclusively for the transportation of merchandise or express and in the case of passenger cars where the space devoted to the transportation of such commodities should exceed 16 sq. ft. the actual weight of the car and the contents should be included. The commission decided, however, that the weight of the passengers was so variable and uncertain a quantity as to be practically impossible of exact determination and that to omit the load in the case of passengers and to include it in the case of merchandise would under certain conditions result in discrimination. For the sake of simplicity, therefore, it was determined to omit the weight of the load altogether. It was not contended that this omission would result in exactly the same proportioning of cost as would be the case if the loads were included, but it was believed that the results could be determined with sufficient accuracy without knowing the exact tonnage.

COMPENSATION FOR ELECTRICAL ENERGY

Owing to the greater reliability of the energy output it was conceded by the Milwaukee Northern Railway to be advantageous for The Milwaukee Electric Railway & Light Company to supply the current over the tracks from Fifth to Sixth Street. This company proposed that the Milwaukee Northern Railway should pay the sum of 1 cent per kw-hr. for all current actually consumed. The Milwaukee Northern Railway did not criticise the 1 cent per kw-hr rate as being excessive, but it objected to this basis on the ground that this figure was greater than its own cost and that it should not be put to any additional expense in using the power of the other company because the latter's cars were operated over its own tracks. No figures were offered, however, to show the exact cost to the Milwaukee Northern Railway under its own proposal. Although on general principles the commission felt that it would be fair to both companies for The Milwaukee Electric Railway & Light Company to charge a rate equal to the Milwaukee Northern Railway's own output cost for energy, still it considered that any attempt to fix such a rate would be likely to result in disputes. The amounts involved in the case were held hardly to justify the time and expense necessary for a full investigation of this on the part of the commission, and since the rate offered by The Milwaukee Electric Railway & Light Company admittedly was not excessive, it was adopted. The rate is subject to revision at the end of any fiscal year upon the application of either company to the commission.

DUTIES OF COMPANIES

According to the decision of the commission, the Milwaukee Northern Railway is to make the necessary changes in the arrangement of its tracks and overhead installations between Fifth and Sixth Streets. The Milwaukee Electric Railway & Light Company is to stand the expense of connecting its double track with that of the other company by suitable frogs and switches and also the expense of making all necessary connections between the overhead systems.

After the commencement of the joint use of the tracks the Milwaukee Northern Railway is, at its own expense, to maintain, replace and renew the double tracks and the overhead system. The Milwaukee Electric Railway & Light Company is to maintain, replace and renew all frogs and switches and the connections between the overhead system of its own line and that of the section on Wells Street.

The Milwaukee Electric Railway & Light Company is to furnish the electrical energy required for a period of three years beginning at the commencement of joint operation. At the expiration of this period, upon the application of either company, the commission will open the question of the further supply of electrical energy and the conditions under which the same shall take place.

On or before the first day of each month the Milwaukee Northern Railway is to pay The Milwaukee Electric Railway & Light Company for the power used at the specified rate of 1 cent per kw-hr. The amount of energy consumed by the Milwaukee Northern Railway is to be considered as having the same ratio to the total energy drawn from the overhead system on the section of Wells Street in question as the ton miles operated over the tracks by the Milwaukee Northern Railway bear to the total ton miles. The energy is to be measured by suitable meters located on Wells Street, to be installed at the expense of The Milwaukee Electric Railway & Light Company. Provision is made for an examination of the meters in case of suspected error and for the payment of the test by the Milwaukee Northern Railway in case the meters do not register in excess of 2 per cent above normal, the cost of the test otherwise being borne by The Milwaukee Electric Railway & Light Company.

On or before the last day of each month The Milwaukee Electric Railway & Light Company must pay to the Milwaukee Northern Railway the following amounts: (1) Such proportion of the monthly cost to the Milwaukee Northern Railway of maintaining in good repair the Wells Street section situated on the south side of the street as the ton miles operated thereover by The Milwaukee Electric Railway & Light Company bear to the total ton miles. (2) A similar proportion of the monthly cost of maintaining the tracks on the north side of the street. (3) Such proportion of the monthly net cost to the Milwaukee Northern Railway of renewing, replacing and reconstructing that part of its system (including paving) on the south side of the street as the ton miles operated thereover by The Milwaukee Electric Railway & Light Company bear to the total ton miles. (4) A similar proportion of the monthly net cost of renewing, replacing and reconstructing the track on the north side of the street.

The net cost to the Milwaukee Northern Railway of replacements, renewals and reconstructions is to be determined as follows: The commission is to determine the initial accrued depreciation as of the date of the commencement of joint operation and the final accrued depreciation at the time of the lawful expiration of joint operation. The difference between these shall be added to or subtracted from the cost of all renewals, replacements and reconstruction during the life of the order and the result shall be considered the total net cost. The monthly net cost shall be that amount of replacements, renewals and reconstruction due and payable each month, but the difference between the initial and final accrued depreciation shall be considered as falling due only when operation under the order of the commission has lawfully terminated. The initial accrued depreciation shall be taken as $175 for the southern section of the track and $417 for the northern section.

On or before the last day of July The Milwaukee Electric Railway & Light Company is to pay to the Milwaukee Northern Railway the following amounts for the use of the latter's track and other property: (1) Such proportion of the annual taxes paid by the Milwaukee Northern Railway upon the part of the system (including paving) situated on the south side of Wells Street between Fifth and Sixth Streets as the ton miles operated by The Milwaukee Electric Railway & Light Company bear to the total ton miles. (2) A similar proportion of the annual taxes paid for the part of the system on the north side of the street. (3) One-twelfth of such proportion of an annual return of 8 per cent of the value new of that cost of the Milwaukee Northern Railway's system (including paving) situated on the south side of the Wells Street section as the ton miles operated by The Milwaukee Electric Railway & Light Company bear to the total ton miles. (4) One-twelfth of a similar proportion of an annual return of 8 per cent of the value new of the line on the north side of the street. The values new shall be taken as $3,240 for the portion south of the center line of Wells Street and $2,930 for the portion north of the center line.

On or before the twentieth day of each month each company must render a statement to the other company showing the ton miles it has operated. The Milwaukee Northern Railway is to include in its statement the amounts paid during the previous month for maintenance and renewals, the amounts paid in connection with the portions of the track on the north and south sides of the street being kept separate. On or before the twentieth day of each July the Milwaukee Northern Railway is to render to the other company a statement showing the amount paid for taxes on the two separate portions of the line. Each company is to give to the other company access to its books and records for the purpose of verifying the accuracy of any of its reports. Any over-payment or under-payment is to be adjusted yearly, June 30 being considered as the end of the fiscal year.

CHICAGO & MILWAUKEE ELECTRIC RAILWAY

The case between The Milwaukee Electric Railway & Light Company and the Chicago & Milwaukee Electric Railway is similar to the above, with the exception that the line involved tracks on Wells Street from Second to Fifth Street.

SUPPLYING THE ELECTRICAL ENERGY

The chief point of contention in this case was in regard to which company should supply the power for the operation of cars. The Milwaukee Electric Railway & Light Company stated that it was willing to supply the power at a lower rate per kilowatt than it costs the Chicago & Milwaukee Electric Railway for power delivered to its trolley wire under present conditions, and also that it could furnish a more reliable supply than the other company for the reason that its source of supply in the district would be close enough to enable it to furnish current of good voltage and because it has several feeder cables available so that the supply would not be dependent upon a single cable. The Chicago & Milwaukee Electric Railway, however, insisted upon its right as owner of the property to furnish the necessary power and contended that under its present power contract with The Milwaukee Electric Railway & Light Company the minimum consumption limit would be passed if it did not furnish the power for Wells Street and it would be obliged to pay double for a portion of its power.

The commission stated that it would be possible to string two separate trolley wires so that each company could use its own power. Such an arrangement would simplify matters of bookkeeping and compensation, but under it opportunity would exist for cars of one company to take power from the wires of the other company by merely shifting the trolley pole. A mistaken sense of loyalty on the part of employees, a personal grudge against the other company or an appreciable difference in the potential of the two power supplies, leading to an easier and faster operation of the cars, might cause this taking of power from the wrong wire. Such a theft of power would be difficult to detect and guard against, and even though no intention of theft actually existed, the situation would create an opportunity for suspicion and recrimination between the companies. For these reasons the commission did not feel inclined to order the installation of two sets of trolley wires.

The commission took the general view that the company owning the tracks should be permitted to furnish the power, provided it could furnish power reliable in character and sufficient in quantity. The investigation of the commission, however, showed that the Chicago & Milwaukee Railway buys power from The Milwaukee Electric Railway & Light Company and transforms it to a 625-volt d.c. current at its substation, situated at the southern city limits. The current is transmitted from the substation to the trolley over a 750,000-circ. mil feeder cable, extending to a point on Wells Street within 45 ft. of Second Street, a distance of approximately 3¼ miles. While the Chicago & Milwaukee Electric Railway could probably take care of the ordinary power requirements arising from the joint use of tracks on the Wells Street section, the commission felt that it was not equipped to supply the current that might occasionally be required under emergency conditions. With a 750,000-circ. mil feeder cable 3¼ miles long, two 3-0 trolleys and a double-track rail return, a blockade of traffic on the Wells Street section might lead to a voltage drop of 380 volts or more, which could not be considered good practice. Then, too, the actual cost of transmitting a.c. power to the interurban company's substation at the city limits, transforming it and turning it back to Wells Street would be greater than the actual cost of supplying the current direct from the Oneida Street or the Commerce Street station of The Milwaukee Electric Railway & Light Company, both of which are near the Wells Street section. Finally, as regards the contractual minimum consumption of power as between the Chicago & Milwaukee Electric Railway and The Milwaukee Electric Railway & Light Company, the commission found that the former company could use to advantage on other portions of its system the small amount of current it would not use on Wells Street in case the power there should be furnished by the city company. The commission decided, therefore, that The Milwaukee Electric Railway & Light Company should furnish all the electrical energy required for the joint operation of cars for a period of three years, beginning at the commencement of joint operation. At the expiration of this period, upon application of either company, the commission will determine the question of future supply and the governing conditions.

COMPENSATION FOR ELECTRICAL ENERGY

The Milwaukee Electric Railway & Light Company proposed to furnish power at the rate of 1 cent per kw-hr. Statement was made during the hearings that the Chicago & Milwaukee Electric Railway under its present arrangement for power pays from 1.4 cents to 1.7 cents per kw-hr. As this statement was not refuted, the proposed rate was fixed.

DETAILS OF ORDER

The Milwaukee Electric Railway & Light Company is ordered to make the necessary connections between its overhead system and that of the other company and also to join its double track with that of the Chicago & Milwaukee Electric Railway. From the time of joint operation the Chicago & Milwaukee Electric Railway is to maintain, replace and renew the double-track and overhead system on Wells Street from Second to Fifth Street, and The Milwaukee Electric Railway & Light Company is to maintain, replace and renew the connecting frogs and switches and the connections between the overhead systems of the two companies.

DIVISION OF ENERGY

The amount of energy consumed by the Chicago & Milwaukee Electric Railway is to be considered as having the same ratio to the total energy drawn from the overhead system of the Wells Street section as the ton miles operated by the Chicago & Milwaukee Electric Railway bear to the total ton miles operated over the track. In the determination of the number of ton miles, only the weights of the cars are to be considered.

PAYMENTS

On or before the last day of each month The Milwaukee Electric Railway & Light Company is to pay to the Chicago & Milwaukee Electric Railway such proportions of the monthly cost to the Chicago & Milwaukee Electric Railway of maintaining its system (including paving) between Second and Fifth Streets on Wells Street in good condition and the monthly cost of renewing, replacing and reconstructing it as the ton miles operated thereover by The Milwaukee Electric Railway & Light Company bear to the total ton miles. In computing the net cost to the Chicago & Milwaukee Electric Railway of renewals, replacements and reconstruction, the same procedure is to be followed as in the case of the Milwaukee Northern Railway. The initial accrued depreciation is set at $2,438.

The following additional payments are to be made by The Milwaukee Electric Railway & Light Company: (1) One-twelfth of such proportion of an annual return of 8 per cent of the value new of the section as the ton miles operated by The Milwaukee Electric Railway & Light Company bear to the total ton miles, this value new to be considered at the date of this order as $17,654. (2) Such proportion of the annual taxes paid by the Chicago & Milwaukee Electric Railway on the section Electric Railway & Light Company bear to the total ton miles. This payment for taxes is to be made on or as the ton miles operated thereover by The Milwaukee before the last day of each July.

Conferences on South American Trade Conditions

The National Foreign Trade Council has issued a statement calling attention to certain fundamental conditions surrounding South American trade which must be taken into consideration by United States manufacturers before existing trade can be improved. The chairman of the council is James H. Farrell, president United States Steel Corporation. The council consists of thirty-five national representatives of manufacturers, merchants, railroad and steamship men and bankers, representing all sections of the country and collectively standing for the general interest of all elements engaged in foreign trade. The statement discusses the characteristics of South American trade, the influence of the European war upon commerce and the need of better banking and credit facilities between South America and the United States.

In view of the widespread attention and comment that has been given to the present trade opportunity in South America, the industrial bureau of the Merchants' Association of New York has been investigating South American trade conditions. In its issue of *Greater New York* of Sept. 7, it publishes an interview regarding general conditions and cautions applying to commerce as a whole. In its future issues it intends to publish a series of articles covering specific opportunities in different countries and the grades of goods demanded in different lines, such as electrical goods, machinery, etc.

A conference between Latin American diplomats and various bankers and representatives of exporting houses, called by Secretary of State Bryan, was held in Washington on Sept. 10. The development of the trade of the United States with South American countries was the subject of discussion. It is said that nearly all South American countries are looking to the United States to supply the exports formerly furnished by Europe, and also that these countries will call upon United States banking houses for more than $100,000,000 of capital to develop their domestic resources.

Kansas has been progressing rapidly in the matter of transit facilities. Five years ago there were only five interurban railways in that State. Now there are sixteen, some of them still in course of construction. The expansion has been due to the awakening of Kansas to the fact that interurban service is an important adjunct of commercial development.

Electric Railway Trade Prospects

Additional Opinions from Electric Railway Manufacturers and Others Concerning Effect of European War on American Trade, Domestic and Foreign—Special Discussions on Increasing South American Commerce by Theodore Stebbins, Gano Dunn and Robert W. Hunt

The ELECTRIC RAILWAY JOURNAL of Sept. 5 contained a compilation of opinions of various electric railway manufacturers regarding present commercial conditions, the probable effect of the European war on both domestic and foreign trade and the proper methods to be used for the improvement of South American trade. Answers from additional manufacturers in regard to these same points follow in part:

H. W. Johns-Manville Company, New York.—This company is meeting considerable difficulty in manufacturing certain of its products on account of the shortage of supplies from foreign countries. Among these are cork from Spain and sal ammoniac from England. A certain amount of sal ammoniac can be obtained in this country, but it is usually of an inferior quality. Difficulty is also being experienced in obtaining suitable quantities of rubber. A large amount of orders is being received, although the tendency shown is toward small amounts.

Crocker-Wheeler Company, Ampere, N. J.—Dr. Schuyler S. Wheeler, president, believes that the cessation of imports due to the war will have no important bad effects upon his industry, because, unlike most others, it uses exceedingly little foreign material. Moreover, all industries, even those that have used much imported material, can adjust themselves to the use of domestic material without serious consequences, except possibly in a few cases. Aside from the reduction of business in this country caused by the cessation of exports, much of the dullness so generally discussed is owing to anticipated slight increases in the cost of the finished product, but this increased cost will be disregarded when the available supply is depleted. There will be a considerable restriction of business for a time owing to the natural conservatism which holds owners back until they have ascertained the exact status of their product under the new conditions in which cost changes, even though very slight, are for the moment considered important. The depression and loss caused by the war will, of course, be largely, though not fully, offset by the gains in business.

Griffin Wheel Company, Chicago, Ill.—While this company has some business in the Orient, it has not been able to meet German, English and Belgian competition in South America. Most South American railways require a steel-tired wheel for both passenger and freight equipment. In order for an American chilled-iron wheel company to obtain much business from railways prejudiced to the steel-tired wheel as well as disposed to purchase in Europe on account of European investments, it will require not only an educational campaign but also more friendly relations between American capitalists and South American railways. While it is possible that American wheel manufacturers may be able to obtain the South American business during the European war period, it is doubtful whether they will be able to retain it after the war has ceased. The company maintains agencies in Argentina and China, which have been instructed to make a strenuous effort to obtain the orders formerly placed in Europe. Aside from the prospective foreign business, the European war has not affected the company's American trade. The total business to date approximately equals that of last year. Orders for wheels for new equipment, however, are at a minimum, since American railroads do not care to finance new propositions on a 7 per cent interest basis. If the European situation is continued this company may be affected by its failure to obtain the 80 per cent ferro-manganese used in manufacturing its high-carbon chilled-iron wheels. It is believed, however, that before the supply is exhausted, American concerns will be in a position to supply satisfactory ferro-manganese. It is possible to use a substitute, such as ferro-chromium, but this would make an increase in the market price of chilled-iron wheels necessary.

Wendell & MacDuffie Company, New York.—This company, which deals in electric railway cars and equipment, is making preliminary arrangements for possible future South American business. Realizing that the initiative must be taken in this country to develop business and that the financial limitations in South America will tend to discourage development, plans are being made through manufacturing companies represented, to investigate commercial opportunities, supply the necessary technical skill and arrange for credit as required. Preliminary arrangements have already been made with one of the large banks for the last-named purpose. One of the interesting war developments has been a revival of inquiries in the foreign field where the company formerly did a large business and advertised widely. The present inquiries are based upon advertising discontinued years ago.

Niles-Bement-Pond Company, New York.—Walter L. Clark, vice-president, reports a general depression in the machine-tool trade owing to tightness of the money market, the principal encouraging feature being some demand from the warring countries for tools. One large order for approximately $500,000 of tools has been received recently by the Pratt & Whitney Company. As the company is not dependent in any way upon the warring countries for materials, there is no direct embarrassment resulting from the war. The South American business has not as yet been affected.

The Protective Signal Manufacturing Company, Denver, Col.—S. L. Shober, president of the company, states that no material used by this company is purchased from abroad. Domestic business will be affected by the war only to the extent that the present financial complications restrict all business enterprises. The foreign business of the company is at present too small to be affected. The company expects to take up the question of developing trade in South America, but now its chief attention is being paid to domestic business.

Keyes Products Company, New York.—Thus far war conditions have not seriously affected this company. The company uses foreign material but believes this can and will be produced in this country. As yet, however, the company has not regarded it as necessary to consider this phase of the matter seriously. Inasmuch as the company's business is largely with ship owners and builders and railroads it is safe to assume that its business will ultimately be much curtailed. The foreign business of the company will be practically at a standstill. No more efforts than usual have been made to develop South American trade, although it is felt that the attention being given by financial men to the establishment of better banking facilities with South American companies will go far toward stimulating the ambition and efforts of American electrical and other manufacturers.

The Thew Automatic Shovel Company, Lorain, Ohio. —According to F. A. Smythe, president, very little foreign business is done by this company and practically no attempts have been made to secure orders of this nature. No material is imported from foreign countries. No effort is being directed at present toward securing South American business, and it is not clear whether the opportunities for securing such orders are materially increased as a result of the existing European conflict.

Yale & Towne Manufacturing Company.—Henry R. Towne, president, says that the United States is the only great industrial nation whose industries are not disjointed by the present European war. The country is exceptionally sound and strong financially. Its vast industrial facilities, while at present not fully employed, are ready to respond immediately to an accelerated demand whether at home or abroad. Under present conditions there is no cause for alarm, but there is much to justify the early expectations of a betterment of business conditions in this country. Mr. Towne believes that American foreign trade will soon be resumed and that domestic industry and commerce will soon show signs of recovery and may by the end of the year become very active. In brief, he advises the exercise of patience for the present and the maintenance of confidence for the near future.

Street Railway Signal Company, Philadelphia.—Broader inquiry from railways and the booking of some substantial orders are viewed by this company as making a trend toward business improvement, the wholesome effect of which must be felt in various lines. Robert W. Withington, president of the company, says he regards the outlook as very promising and believes the railways, in going ahead with improvements to their systems, are harbingers of better all-round business conditions.

Railway Improvement Company, New York.—A. J. Pizzini, vice-president and general manager, states that no imported materials are used in the goods manufactured, with the exception of some chemicals in the porcelain cover of the sanitary straps. The war has caused the complete dropping off of foreign business, including the cancellation of some orders on hand. Domestic business has been affected temporarily, but a strong reaction with increased sales will come as soon as financial conditions adjust themselves. The company is now trying to arrange for a representative to be sent to South America with a view of introducing its goods into that market.

The Baldwin Locomotive Works, Philadelphia.—According to Alba B. Johnson, president of the company, there are no imported materials used in the manufacture of electric railway trucks, so that the company is not concerned with the necessity of finding new sources of supply or using substitutes. The cessation of normal financial conditions owing to the closing of the stock exchanges and the impossibility of selling securities or effecting loans, has caused a total suspension of domestic business. This is true of foreign business as well. The company's agencies throughout South American countries are giving close attention to the opportunities for business, although these countries also are for the present affected by financial conditions. With the restoration of normal conditions, Mr. Johnson believes that there should be a considerable increase in trade relations with South America.

Power Specialty Company, New York, N. Y.—L. B. Nutting, general sales manager, states that his company obtains from this country practically all of the materials, including chiefly iron and steel, which are necessary for the manufacture of its superheaters. Since contracts for superheaters are not generally placed until three or four months after boiler equipment has been purchased, it is too early at the present time for any appreciably decreased demand for new equipment to be felt as a result of the European war. The foreign business is handled independently by an English office and factory, which are still in operation. The company has no representatives in South America, since this region is not considered much of a field for superheaters.

Morgan Crucible Company.—H. W. Knott, manager, states that the raw materials used by his company to manufacture its carbon brushes include carbon or graphite, which is obtained from England, and American copper and American-made machinery. The war has not affected its supply of materials from England, and should the supply be cut off, the Brooklyn factory of the company, which manufactures brushes for the United States, has enough stock on hand to continue its output for at least one year. The war has interfered very little with its domestic business. In fact, in August the company experienced the most prosperous month it has ever had and this present month an even greater output is anticipated. European trade is conducted independently by companies in the various countries on the continent. This trade has not been affected very much so far as is known, excepting in the countries in which war is being actually carried on. South American materials are manufactured separately by a company with offices and factory in Buenos Aires. No steps, therefore, along the lines of better credit facilities are necessary in order to increase this business.

Dearborn Drug & Chemical Company, Chicago, Ill.—The European war situation has not materially affected this company's business, since it is so closely related to economical operation that it is looked upon as a necessity rather than a luxury. Moreover, the chemicals necessary in making water analysis, which is the principal part of this company's business, are purchased from American manufacturers, so that the cutting off of the German chemical supply causes no inconvenience. At the company's agencies in the Orient, including the Philippine Islands, Hawaiian Islands, Japan, Corea and China, business has been only slightly retarded. In South America, where the company also maintains an agency, an opportunity is offered for increased business. Heretofore Europe has furnished the chemical engineering knowledge to South America, so that the present interruption of communication offers to America a possibility of increasing business, at least temporarily.

In addition to the companies quoted above, a number of companies were interviewed who were willing to express their opinions but did not wish their names quoted. A fuse manufacturing company uses practically no foreign materials and the stock of the few imported materials used is adequate to serve the requirements for a long period. Moreover, these few imported materials can in all probability be produced in the United States. A serious temporary decline is anticipated in the domestic business. The company is confident that a good business can be developed in South

America and at the present time advertising appropriations for trade papers in that field are being increased. The company is also endeavoring to secure local representatives.

A large manufacturer of mica for commutators expresses the opinion that the demand for its materials will not be appreciably decreased during the war because it receives much larger orders from electric railways for repair work than it does for new equipment. This repair work is now increasing in demand because railways are showing an unwillingness to scrap their old motors and pay the advance in price on new equipment. This same company does not consider it necessary in its own case to take any unusual steps toward promoting South American trade facilities, because in Buenos Aires, the only South American electric railway center of importance outside of certain large properties which already have purchasing agencies in New York, it believes the electrification is not yet old enough to require any large amount of repair work.

One of the large companies in the electric railway manufacturing field says that practically none of its business is affected by the war as regards the receipt from abroad of raw materials. Its domestic business will undoubtedly be interfered with, as far as extensions of present systems and the building of new plants are concerned, owing to the complete unsettlement of credits and sales of securities brought about by the tremendous foreign demand for money. It is hoped that business in miscellaneous supplies and renewals will increase in a number of lines, as this naturally follows where equipment is not being purchased. Foreign business has not been materially affected by the war, excepting as regards transportation of some goods on old order. The company is giving active attention to the trade situation in South America. In due time favorable results will be seen, but a great deal of careful planning and hard work are requisites for any material success. Large stocks of foreign-made electrical goods are still available in many sections of South America, and if the war should terminate before this supply is exhausted, the demand for American-made goods would naturally grow very slowly.

A manufacturer of car heaters considers that while domestic business will be delayed until it will be possible correctly to foresee the outcome of the European war, with the resumption of shipping there will be a great industrial revival. The company believes that its product is not marketable in South America on account of the climate. This might not apply to the extreme Southern part of the continent, but there is not sufficient business there to warrant any sales activity.

It is stated by another company that steel mills have raised the price of structural steel and bars used for raw material on account of the increased price of ferromanganese. It is believed, however, that the ferromanganese situation is easing and that there are deposits in this country which have not been developed. Customers are having difficulty in financing their requirements for construction purposes. The company will be busy for some time with orders on hand, but a period of decline is expected later. A comparatively small amount of business is carried on in foreign countries, no particular soliciting having been done. Doubt is expressed as to the possibility of a field for overhead construction materials being developed in South America. It is felt that it is better to confine attention to the trade in the United States, for this affords an ample field for the company's efforts.

According to a railway supplies manufacturer, the potassium cyanide used in the plating department is imported and at present there seems to be a shortage. It is not known whether this can be obtained from neutral countries or whether it can be manufactured in this country. The sales of supplies and fare registers will be affected only through the restriction of railway earnings and financing of railway extensions, and the company states that pessimistic reports have been received from electric railway customers regarding earnings. The company does not look forward to an improvement in the South American conditions for the reason that the field there has been already well covered.

A large brake manufacturing company reports that it has sufficient work at the present time to keep it busy for a long period, and when it has caught up with the deliveries of orders now on hand it believes that general business will have taken a turn for the better. This company at present is not interested in the development of foreign trade on account of the fact that all its business is confined by contract to North American countries.

A prominent manufacturer of electrical wires and cables states that requisitions for maintenance work are now so much in excess of what they were a few years ago that orders for upkeep constitute what in the old days would have been considered good, big business. Timidity in the security market, however, has made new business in wires and cables for construction and extensions comparatively slow during the last year. This condition existed before the war. With regard to the electrical field in general, it is pointed out that the United States need look abroad for practically none of its manufacturing materials. There is an abundance of cotton and apparently the price will be lower than for several years. At the beginning of the war there was an unnecessary scare regarding rubber, because it was feared that the Ceylon supply would be cut off. That is not the case. Moreover, there is enough good rubber available from Africa, South America and Central America to meet the demands of the world, particularly so since there is a reduction in this demand. It is expected that the supply sources are sufficient in capacity to keep the prices within limits established during the last year or two.

UNITED STATES TRADE WITH PAN-AMERICA

Trade of the United States with other American countries in the fiscal year ended June 30, 1914, aggregated $1,303,000,000, or 33 per cent below the high record of 1913, and constituted 30 per cent of the entire commerce handled by domestic ports. Of this large New World commerce, $956,000,000 was with North America and $347,000,000 with South America.

United States imports from North American countries, valued at $427,000,000 in the fiscal year, were chiefly from Canada, Cuba, Mexico, the Central American States and the British West Indies. Exports to North American countries, $529,000,000 in value, were chiefly to Canada, $345,000,000; Cuba, $69,000,000, and Central America and Mexico, each about $39,000,000. The United States supplies a larger proportion of the leading countries of North America than any other nation, and in the case of Canada, Central America and Cuba more than all other parts of the world combined.

Of $223,000,000 worth of imports from South America, nearly one-half were from Brazil, about 20 per cent from Argentina, and the remainder chiefly from Chile, Colombia, Venezuela and Peru. Nearly one-fourth of the total exports of $125,000,000 value to South America went to Brazil and more than one-third to Argentina. In sharp contrast with the high position of the United States in the North American markets is its low rank among the nations selling goods in South America, where in the case of such important countries as Argentina, Brazil and Chile, only about 15 per cent of the imports were from this country. South America as a whole imported in 1912 $965,000,000 worth of foreign goods, the share of the United States being about 14 per cent.

SOUTH AMERICAN TRADE CONDITIONS

NEED OF BETTER UNDERSTANDING OF STABILITY AND PROGRESS OF SOUTHERN REPUBLICS—OPPORTUNITY FOR CONSTRUCTIVE WORK IN SOLVING SALES, BANKING AND SHIPPING PROBLEMS

BY THEODORE STEBBINS

The development of our commercial relations with South America becomes a freshened subject with the outbreak of the European war. The consequent stoppage of European shipments will compel South America to buy a few more things from us. To what extent and for how long can we hold their valued trade? Let me say at once that to hold the principal part will be no easy task. In making the effort it is vital to understand the reason in the past for our small proportion—about one-seventh—of their trade.

The dominant classes in South America are European by origin, and admixture and the constant flow of emigration. The relations with Europe of blood and race are manifold. The youth obtain their education in Europe. Those of means travel in Europe. The rich retire to Europe. All are bound to Europe by ties of race, blood, sympathy, custom and fashion. The habitations and the habits of the people are pronouncedly European. Literature, poetry and the arts flourish. Their best people have a more distinctly European education, culture and charm than our own.

Between North and South America ignorance, indifference and distrust predominate. Our most exiled citizens have found South America a convenient refuge, and their activities have too largely created South America's opinion of us. When I was residing in the capital of one of their smaller republics a jewelry store was robbed. All Americans were promptly locked up on suspicion except those of known diplomatic or business connections. The newspapers are responsible for the continuance of much of this distrust. For the same reason that some of our newspapers seek profit in circulation at the expense of morals by giving an undue prominence to scandals and crimes, our newspapers do not find "good news" in the peaceful achievement of South America but publish exaggerated and absurd rumors of "revolutions." Eighty per cent of South America, measured industrially, has had strong stable governments for many years. Likewise, the South American newspapers take note of our bloody industrial wars in Colorado, etc. So the readers on each side get the worst pictures of the other. And remember this. Our lawless destruction of life and property exceeds theirs. So let us have more respect for the South Americans. And let us view their trade requirements as an expression of their habits and customs and in a sympathetic cosmopolitan spirit. In brief, we must establish social relationship as the broadest basis of general trade. Its absence has been the fundamental cause of our failure in general South American trade.

Next in importance in determining the origin of imports I would call attention to the extensive railroad systems and other enterprises established in South America of recent years. The British, German, French and Belgians have gone into South America with materials of their own manufacture and built those railroads and other things, and own and operate them. Our manufacturers can stand little show, or none, in the sale of these construction and supply materials, until we become a lending, not a borrowing, nation, and can go forth to build foreign railroads and the like. Our own railroad field is being made so unprofitable by our government that our own surplus capital may soon seek foreign fields.

Direct banking connections with South America are a necessary aid to trade. Our own self-imposed laws have forbidden foreign banking branches but now have been amended to allow them, and our largest bank, the National City of New York, is proceeding to establish South American branches with broad functions and dealing with the situation in a very liberal and intelligent manner.

Between North and South America no regular steamship lines operate tonnage adequate for any considerable trade. The present steamship laws which have driven our flag from the seas are in process of amendment. What Congress will do remains to be seen. Government owned ships are proposed. Are our politicians competent to run them? In any case the law should not longer create handicaps for our private ship owners. The law obliges expenses in wages and otherwise about 30 per cent more than those of foreign competitors. So Congress is now legislating to permit or prevent the necessary shipping link in our South American trade connections.

Finally, to explain the smallness of our South American trade our manufacturers have their failings, namely, to study and supply the character of goods needed, to send suitable salesmen (imagine a foreign salesman attempting to sell goods to our merchants without knowing a word of our language!), to give terms of payment as long as European competitors and, with goods once sold, to pack and ship them properly.

The general war in Europe has suddenly shut off European exports to South America and our exports to Europe. Cannot our European exports be diverted to South America? Apparently, it is the opportunity of a generation. Unfortunately we are not prepared at once to take the full benefit of the situation. It will take a long time, not a short time, to get acquainted with these countries and their people and their needs, and to establish foreign branch banks and steamship lines and commercial branches and, finally, the export business itself. But let us now make a serious beginning. And we must secure the foothold now to secure the immensely larger trade of future South American development. The means by which this may be done are beyond the scope of these few paragraphs.

South America is a continent of vast areas with corresponding diversity of climate and products. The average North American seems to picture it as a tropical region only. Conditions of the whole should not be drawn from conditions of a part. Argentina, Brazil and Chile are the principal importing countries and have stable governments, and the remaining countries are relatively negligible. All the large cities have modern conveniences. Buenos Aires and Rio de Janeiro have more than a million inhabitants each and enjoy European luxuries in greater measure than we. The leading cities are served by electric light and railway systems excellently constructed under European specifications.

The trade should be sought by studied and intelligent and persistent efforts through co-operative methods. While our general South American trade is small, yet in certain industries it is large. The agricultural machinery trade is secured efficiently by one international concern (which, incidentally, our government is seeking to destroy). The increasing excellence and cheapness of our automobiles should secure a large market for them. American sewing machines and typewriters find a large market. But Europe gets the preference in the ordinary items of domestic consumption, owing to the European habits of the consumers, and on construction material and supplies, owing to European ownership of the purchasing companies.

Our electrical manufacturers have made intelligent, well organized and long continued efforts to sell electric apparatus and have secured a gratifying proportion of the business, considering that the South American operating companies are of European ownership. All such business can be secured by one simple means, namely, the purchase of the operating companies by our own capitalists. The European war will compel a low purchase price. The "reasonable return" on investment, so glibly discussed here, so universally evaded in terms of per cent, by which our utilities are partially confiscated, that is, robbed of a part of their proper market value, gets a fairer interpretation in South America. So our constructive builders of industry may well consider the transfer of their activities to South America.

REVIEW OF BUSINESS SITUATION

GANO DUNN BELIEVES THAT EFFECTS OF DESTRUCTION OF CAPITAL BY EUROPEAN WAR WILL BE COUNTERBALANCED BY INCREASED EXPORT TRADE

Gano Dunn, president J. G. White Engineering Corporation, who was in Europe at the time war was declared, has given, at the request of the ELECTRIC RAILWAY JOURNAL, a statement of his views in regard to the effect of the conflict upon business conditions in this country. It is as follows:

"First—An enormous amount of the world's capital has already been destroyed and more will be destroyed. Consequently construction enterprises and new projects of all kinds which flourish on surplus capital seeking investment will be severely checked for a long time.

"Second—Further destruction of capital due to the continuation of the war will probably be greater if the allies are defeated than if Germany is defeated, since the capital of Great Britain, France, Belgium and Russia is much greater than that of Germany and Austria, and it is probable that the former nations would go far toward exhausting their greater joint resources before accepting defeat. The financial and industrial effects of the war, therefore, are involved to a considerable extent in the result of the fighting.

"Third—There will probably be greatly increased exports of foodstuffs and manufactures from the United States, which will mitigate and to some extent offset the tremendous capital losses in the United States resulting from the destruction of security values and the contraction of credits. There will probably be a general increase in interest rates and a certain amount of American capital available for smaller construction enterprises that are near enough home to be locally known and bring out the resources of the very small investor.

"Fourth—South America will suffer not only through lack of European capital, which has been the principal source of supply for the development of her new enterprises and the extension of her commerce, but also severely through the reduced capacity of Europe to take and pay for South American exports. American and Canadian markets will inevitably be benefited by the demand for such South American imports as Europe cannot supply. While these South American purchases will be of much benefit on account of the business they represent, they will be of more value because of the new channels of trade they will open up and the new connections they will establish. Their immediate value should not be overestimated, however, in view of the reduced buying power South American countries will experience from the reduction of their usual exports to Europe.

"Fifth—Any forecast at this time can be presented only as an offhand opinion, since the consequences of the great struggle will so fundamentally affect American international commerce, finance and industry that no one can see clearly the adjustments that must follow."

CANADIAN AND SOUTH AMERICAN COMMERCE

TRADE REDUCTION IN CANADA AND DIFFICULTIES OF SOUTH AMERICAN SITUATION DESCRIBED BY CAPTAIN HUNT

In an interview with a representative of the ELECTRIC RAILWAY JOURNAL, Capt. R. W. Hunt, of Robert W. Hunt & Company, Chicago, Ill., stated that practically all the European and Canadian trade of this company has been brought to a temporary standstill. Some inspection work, however, is being carried on in both these countries, but it represents only a very small percentage of what was under way before the war started. Canada is a large money borrower, principally from England and Belgium. Hence the use of capital for war purposes in these countries has caused practically an absolute cessation of railroad activity, and new purchases have been discontinued. Heavy construction work under way and not completed by the Canadian Pacific, the Grand Trunk Pacific and the Mackenzie interests has been stopped. This has seriously affected all Canadian industries, including rail mills, bridge builders, cement mills and other manufacturing industries dependent upon railway business. There has been more than a 50 per cent reduction in production due to this inactivity of the railroads. The labor market, however, has not been affected by the enlistment of Canadian young men for service in Europe, there being plenty of labor because so many factories have been closed.

While business in the United States has not been so seriously retarded as that in Canada, the closing of the security market, the failure to market the record-breaking cotton market, as well as the restricted grain market, were adverse conditions. The commercial possibilities of South America as an outlet for American trade are not generally understood. There are many conditions which must be overcome, such as the great financial depressions in Argentina and Brazil, which are heavy borrowers of European capital. These countries have a large English, German and French representative population which makes it natural for them to look to Europe for their capital. Mr. Hunt feels that there is little probability of overcoming this prejudice in a short time, since the South American countries are curtailing expenses like this country. If the war continues, however, there will ultimately be an opening, but American manufacturers cannot meet with immediate overwhelming success in capturing the South American markets. Indeed, says Mr. Hunt, so closely are South American markets related to Europe that his company found it advisable to handle all of its South American business through its London office. An optimistic view of the situation, however, indicates that the European war will ultimately redound to American advantage.

The York Railways Company recently inaugurated religious services for its employees at the carhouses on Sundays. On the opening day the entire force was present and joined heartily in the service. Early cars were sent out to different parts of the city for the men, who were all in place by 6 a. m. The services were conducted by a local pastor. The secretary of the Y. M. C. A. and officials of the company were present. General meetings of this character will be held once a month and local meetings every Sunday. The railway company is highly pleased with the results of the meeting.

Toledo Injunction Hearing

The hearing on the Toledo Railways & Light Company's amended bill asking for an injunction against the city of Toledo, Ohio, to prevent the enforcement of the Schreiber 3-cent-fare ordinance and from interference with the company in the withdrawal of its cars from the streets was begun before Federal Judge Killits in the United States District Court on Sept. 8. The city solicitor's department filed no answer, but Judge Killits decided to proceed with the hearing just as if the answer had been filed. He ruled that the company had made a *prima facie* case that the ordinance is unreasonable, although the city might be able to show that it is not unreasonable.

An affidavit from Frank R. Coates, president of the company, showed that from April 1 to Aug. 1, 1914, the road carried 15,913,504 pay passengers. At the rate of fare in effect prior to the passage of the Schreiber ordinance there should have been a stimulation of traffic amounting to 6 per cent. This would bring the number up to 16,868,314. The average rate per passenger carried during that period was 3.9334 cents, which would have yielded a revenue of $663,498 if the old rate of fare, with 3 cents morning and evening, had been in effect. With earnings of $55,000 from other sources the revenue would have been $718,498. Because of the fact that passengers who refused to pay the fare were carried free, the actual revenue for the period was $471,796. The operating expenses amounted to $606,435, showing a loss of $134,637. City Solicitor Thurstin objected to the affidavit on the ground that it was speculative, but the objection was overruled.

E. R. Kelsey's affidavit presented clippings from Toledo papers quoting Mayor Keller and City Solicitor Thurstin as threatening to man the cars with police if the company attempted to collect fare exceeding 3 cents.

Judge Killits said that one of the questions before him was whether this court had jurisdiction. He considered the Schreiber ordinance enforcible in only one way. It is beyond the power of the Mayor of Toledo to attempt to enforce it until the provision in the ordinance determining how it shall be tested is passed upon in a court of competent jurisdiction. The company is entitled to the same protection in court as an individual.

C. E. Murray, auditor of the company, presented an affidavit showing that 7,968,935 passengers had been carried between April 1 and Aug. 1, 1914. A. G. Van Dreisen, chief clerk, was called upon to present some of the company's books of record before adjournment of the forenoon session.

An affidavit from Peter Witt, street railway commissioner of Cleveland, stated that the report of the examination of the company's accounts made by Carl Nau can be understood by any one, whether in the railroad business or not.

On the afternoon of Sept. 9 Federal Judge Killits brought the hearing of the injunction suit to a rather abrupt termination and intimated that the application of the Toledo Railways & Light Company would be granted. The case was submitted to the court without argument and he explained that his formal decision would be prepared and filed a few days later, perhaps on the afternoon of Sept. 11 or on Sept. 14. Further, he said if the decision sustained the company, the operation of the decision would be postponed a few days to allow the people to become acquainted with it and adjust themselves accordingly.

As previously stated, the forenoon of Wednesday was spent in hearing affidavits offered by the company in support of its claims. City Solicitor Thurstin began the presentation of his case just before noon, when Chief Clerk A. C. Van Dreisen, of the company, was called to identify a number of books and records of the company.

Finding that the city was not prepared with evidence to combat the company's statements, as had been expected, the hearing was adjourned until 8:30 a. m. on Sept. 10, but before doing so the court learned that the city did not question the company's report relative to its expenses.

Judge Killits, during the hearing, announced that he would not appoint a receiver for the company. He feels that such a course would delay a settlement of the franchise controversy, which in his opinion should be adjusted just as soon as possible.

At the hearing on Thursday, Judge Killits asked Mr. Thurstin whether on the facts before the court he was contending that the ordinance, if obeyed by the company, would pay running expenses and a return on a fair valuation of its property. Mr. Thurstin replied that this was a matter of calculation. The contention of the city had been from the start that the ordinance passed on Nov. 27, 1913, was a valid and legal ordinance and was such until repealed or passed upon by a court. He contended that the burden of proving it otherwise was on the company; that the measure was *prima facie* a valid ordinance, and that the showing of the company must be conclusive and clear that the company could not operate under it with profit. Mr. Thurstin agreed with Judge Killits that the ordinance was confiscatory if it did not provide for a revenue sufficient to meet operating expenses, maintain suitable service and leave a surplus for a fair return upon a reasonable valuation. In this connection Mr. Thurstin said:

"I would never ask Council or any city official to lend a hand in asking this company to operate if it could not make money."

The judge said that he was glad to know that the City Solicitor's office was not responsible for the ordinance and had inherited the troubles incident to the measure.

Mr. Thurstin protested that the court was attempting to put him in an embarrassing position, whereupon Judge Killits expressed the opinion that the court was warranted in asking advice as to Mr. Thurstin's views. Judge Killits said further that Mr. Thurstin would do the city a service by saying publicly that the ordinance was a mistake if that was his opinion.

In conclusion, Judge Killits said:

"I shall assume, when it comes to the question of fact, that the city has been unable to sustain the ordinance as practicable as far as the rate of fare is concerned under existing conditions. There is no question whatever but there is a presumption that Council, in passing the ordinance acted intelligently, fairly and with a desire to impose conditions with which the company could comply. That is a presumption. But it does not control. In this case we find that the city of Toledo and its officers, in passing the ordinance, had the same information and the same advice that this court has now and that the ordinance is confiscatory and inoperative.

"The conclusion is almost compelling to say that the ordinance was buncombe when passed. That is no reflection on the present administration. It has done its duty in trying to have the ordinance obeyed. These comments from the bench are unusual. So are the conditions in this city. It is unfortunate that so many people have been misled into the belief that this corporation is infringing on their rights. It does seem to me as a citizen that the time has come, whatever our relations may be, to attempt to relieve ourselves of prejudice and to get ourselves and our fellows into the position where we can see things clearly."

The Citizens' Franchise Committee has been inactive pending the decision on this case. Just what move it will now make, if any, has not been outlined, but it is stated that something will be done to hasten a settlement in the mater.

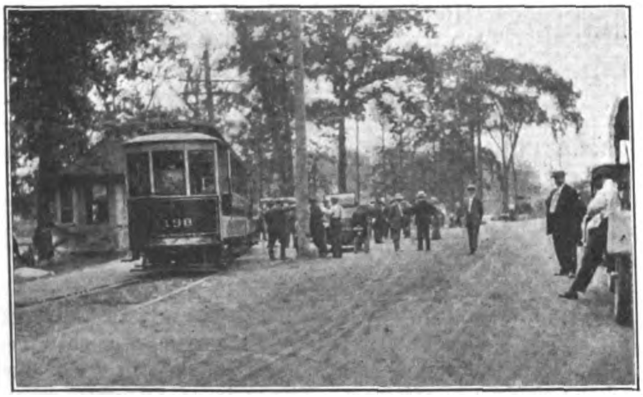
The company was represented at the hearing by Thomas H. Tracy and Rathbun Fuller, while the city was represented by City Solicitor Thurstin and his assistants, E. H. Horton and Mr. Schlatter. Henry L. Doherty and C. A. Frueauff were present.

Henry M. Doherty, chairman of the board of directors, said if the decision is in favor of the company the rates of fare agreed upon temporarily between the company and former Mayor Whitlock will be put into effect and maintained until an agreement on the franchise question is reached. Under this arrangement the company collected a 5-cent cash fare, with a 3-cent straight fare for two hours each morning and evening. Tickets were sold at the rate of six for 25 cents.

Storage Battery System for City Island, N. Y. Built in Seventeen Days

BY W. R. WOOD, FOREMAN STORAGE BATTERY CARS THIRD AVENUE RAILWAY SYSTEM.

The historic village of City Island, 16 miles from New York, has not heretofore enjoyed adequate transit facilities. Through the efforts of E. A. Maher, vice-president and general manager Third Avenue Railway, and leading citizens of City Island, arrangements were perfected whereby the Union Railway took over the existing horse-car line, and extended it to the City Island station on the Harlem Division of the New York, New Haven & Hartford Railroad. One and one-half miles of new track were laid, a waiting station was built at the Pelham Park Boulevard, and a temporary charging station was erected at Orchard Beach within a period of seventeen working days. Twelve of the Third Avenue Railway's storage battery cars were then lightered to City Island, and the new service was inaugurated on Aug. 18, the last horse car passing over the line at 12:15 p. m., followed by the first battery car carrying a party of officials and guests at 12:30 p. m.

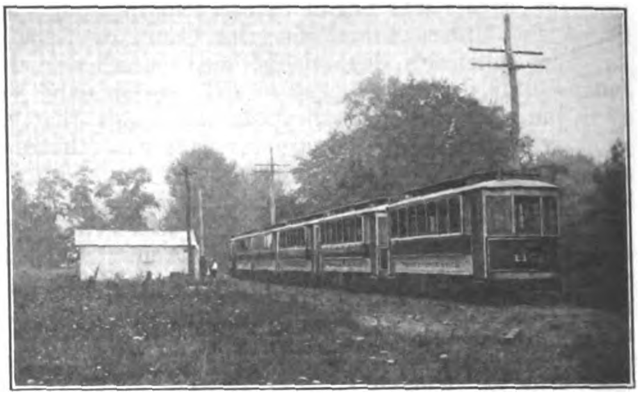


THE FIRST BATTERY CAR

Power for charging is furnished by the Westchester Lighting Company at 220 volts from its two-phase line passing the charging station. Mercury arc rectifiers are used for converting this to direct current at 130 to 160 volts for charging the batteries.

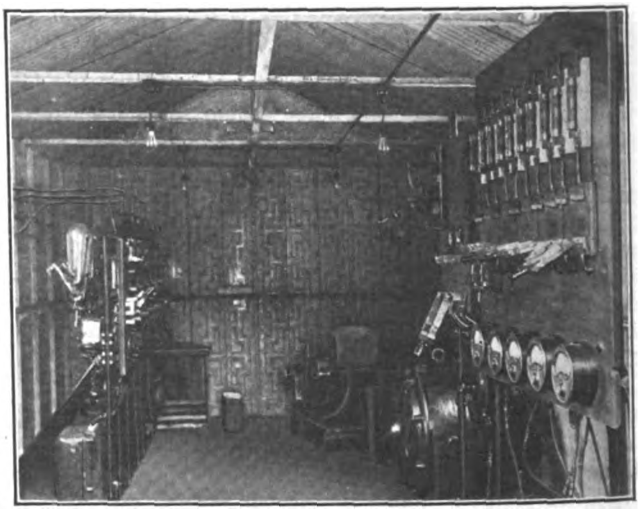
The output of each arc is 50 amp., but for rapid charging reactances have been provided on the d. c. side so that two of the arcs may be connected in multiple for charging a single car at a high rate. A two-phase motor and a 200-amp. generator which were on hand were also installed as a reserve power supply to be used in an emergency.

A galvanized iron building 10 ft. x 24 ft. was erected for housing the charging apparatus, and a siding was laid to accommodate the twelve cars. These cars are equipped with Hess-Bright anti-friction bearings on the armatures and Rollway bearings on the journals. As they have Peacock brakes and are heated by coal stoves located on the trucks, it will not be difficult to attend to all maintenance and repair work on this open siding without pit facilities.



CHARGING STATION AND SIDING

Since its opening the road has been very popular, carrying more than 6200 passengers in a single day. The cars are being operated by men from the old horse-car line and are maintaining a schedule of 9 m. p. h. on an energy consumption of less than 1.25 a.c. kw-hr. per car mile purchased. It is anticipated that as the men become more familiar with the work this performance will be improved. Meanwhile it is expected that the present line, which is laid with 9-in. grooved rail and bonded, will soon be electrified and extended.



INTERIOR VIEW OF CHARGING STATION

Proposals have been made for the electrification of the Eastern Bengal suburban lines. The proposition includes four lines from Calcutta to Naihati and two from Naihati to Kanchrapara. The d.c. overhead system is recommended in place of the third-rail, owing to trespassers. The principal object of the electrification is a financial one, and the consulting engineers report that it will pay to electrify the lines as the gross capital outlay required for the scheme will be $4,406,643, while the annual saving in train operation alone is reckoned at $399,340 in spite of higher speeds and better train service.

COMMUNICATIONS

Steel Sheathing for Car Siding

PITTSBURGH RAILWAYS COMPANY
PITTSBURGH, PA., Sept. 3, 1914.

To the Editors:

I was very much interested in your editorial on steel sheathing for car sides, appearing in the Aug. 15 issue, and particularly with the discussion in the Aug. 29 issue. It would seem to me that, with the thoroughness that Mr. McPherson analyzes the situation, there should be small room for doubt in the minds of those who are actively considering car design of this character.

It might be interesting to state that, some six years ago, the Pittsburgh Railways Company adopted the side-girder type of car construction with a special bulb angle as the top member and a tee section for the bottom member with 1/8-in. sheathing. Some five years ago the company changed the top member to a flat bar, and the bottom member to commercial angle and reduced the thickness of the sheathing to 3-32 in. Lately we have again reduced the thickness of this side sheathing to No. 14 gage sheet steel. Mr. McPherson's assumption and calculations closely resemble those used in the determination of the sizes and members used in the construction of our cars, and some six years' experience and use of cars designed in this manner have demonstrated to us that they are absolutely safe.

The low-floor type of motor car and trail car used in Pittsburgh has its floor load and its equipment load practically balanced over the trucks, and the calculated unbalanced moment on the side girder on these cars is approximately 600,000 in.-lb., which is considerably less than that assumed by Mr. McPherson. In our case, the calculations show that the side sheathing could be entirely omitted without exceeding the accepted maximum fiber stresses for open-hearth steel.

However, there is another factor which in a large measure influences car design and many times takes precedence over theoretical requirements, that is, the factor of utility. To illustrate, assuming that it is entirely safe from the standpoint of strength to omit the side sheathing, no one would think of doing so in this type of car. Therefore, what thickness should the sheathing or plate be to resist shocks in contact with wagon wheels, poles and other street obstructions? What thickness should it be to maintain a reasonably smooth, unbuckled surface? What length of sheet should be used properly to facilitate construction and repairs? Our experience has shown that a 3-32-in. plate is amply thick to meet these requirements, and if desired, it may be used in lengths no greater than the distance between post centers.

The question of post design in car construction influences largely the strength of the side girder, and of all the various types of posts used and considered, the flanged, "U-shape," pressed-steel post offers, in our opinion, the greatest advantage. From the standpoint of strength and lightness, it may be surprising to know that this type of post with its cover plate and the sash and curtain guides weighs less per lineal foot than the smallest commercial section of tee post similarly equipped. Also, with this type of post, gussets at the belt rail and side sill have not been found necessary and do not appear in our construction. I might say further that the use of aluminum alloy for side sheathing has been seriously considered in this country, but its cost up to the present time has been found prohibitive.

Referring to the effect of a top plate or letterboard (either in steel or wood) upon the strength of the side of the car, there is no doubt that a properly shaped plate reinforces the strength of the side girder. We are using a pressed sheet steel letterboard, approaching a channel shape in form, which materially stiffens and strengthens the side of the car. However, if the sections used in the belt rail, side sills and posts are as light as permitted by the design, the required strength and the utility factors, and if, at the same time, the section modulus exceeds that required, such added strength as the letterboard or top plate introduces hardly becomes a factor in the problem. The most important single item in the construction of steel cars is the one of riveting.

I am satisfied, that if all car designers analyze their requirements with the same degree of thoroughness as displayed by Mr. McPherson, the question will be no longer one of opinion but one of fact.

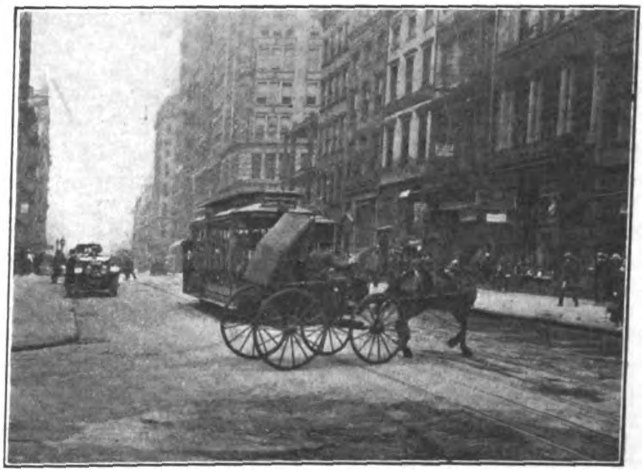
F. R. PHILLIPS, Superintendent of Equipment.

Advantage of Near-Side Stop

NEW YORK, Sept. 5, 1914.

To the Editors:

Of the many kinds of accidents which happen where vehicular traffic is heavy, and for which the street railway company in most cases is not in any way responsible, perhaps the most prevalent are those caused by cars coming in contact with horse-drawn or other types of vehicles. Of this general type of accident, perhaps the most troublesome class is caused by vehicles coming out of a side street and approaching a main thoroughfare without first ascertaining whether any cars are approaching that corner. Drivers and chauffeurs are particularly careless about crossing a street which has double tracks, in that after one car has passed the corner they do not investigate whether another car is coming in the opposite direction.



A NEAR-ACCIDENT AT A FAR-SIDE STOP ON BROADWAY, NEW YORK

The photograph (not posed), reproduced herewith, illustrates the carelessness described. The driver, at a good rate of speed, was coming down the side street directly after a car on the north-bound track had passed the corner, but he did not stop to ascertain whether or not a south-bound car was approaching. What might have been a serious accident was averted by good brakes and the quickness with which the motorman on the car approaching the horse and buggy acted. The driver of the vehicle had whipped up his horse and endeavored to pass in front of the car, but, fortunately, the motorman was able to bring the car to a stop in time to prevent a serious accident. Another interesting point is that a passenger was standing on the running board of the car, preparing to alight. The conductor had apparently given the signal to stop the car, but before that the passenger was already out on the running board.

The illustration indicates that if an accident had occurred the street railway would not have been responsible, yet it would have been put to the needless expense of defending a suit for damages not only to the horse and vehicle but to the driver as well, and the accident might have resulted fatally.

At the point shown the car makes a "far-side" stop. The photograph was taken by the writer recently while standing at the southwest corner of Eleventh Street and Broadway, New York. G. O. SMITH,
Director of Safety, Doherty Operating Company.

A Discussion of the Flagging Rule

ILLINOIS TRACTION SYSTEM
SPRINGFIELD, ILL., Sept. 4, 1914.

To the Editors:

The article appearing in the Aug. 1 issue entitled "Proceed, Protected by Flag—A Fallacy," seems to the writer to merit much more consideration than a mere passing thought, and the lack of comment made on it up to the present time is to be deplored. The writer cannot entirely agree with the article in question, as he feels that it does not clearly outline the governing factors which may have led some roads upon the installation of automatic signals, seemingly to revert back to an obsolete and so-called dangerous practice.

It is not my intention to take issue with the Transportation & Traffic Association, which in 1911 eliminated as unsafe a promiscuous flagging rule. This was undoubtedly the proper course at that time. Instead, this letter is intended simply to point out the difference in the conditions, as they appear in my mind, between those which existed at the time the rule was eliminated and those which are considered in the editorial in question.

Railroads are not dependent upon either the telephone or the automatic signal for their operation, although it is true that both of these devices facilitate and safeguard traffic. To the writer's personal knowledge, a 40-mile division of interurban track, with hourly service, was operated for more than a week with no telephone service whatever, and with very little delay. This was long before automatic signals were considered as a necessity for electric railways, but not before the operating officials, on this particular road, realized the danger in trains proceeding under flag protection, and this method of operation was not allowed. How, then, was this feat accomplished? Simply by running trains according to the printed time-card, and compelling them to make the carded meeting points.

In the editorial under discussion it is pointed out that block signals are, at the present time, considered only as an additional "safeguard superimposed upon the structure of operating rules," but, at the same time, it is argued that, under certain conditions, they must take precedent over the fundamentals of operating methods, which have been in effect for years.

To illustrate: consider a railroad without signals and upon which two opposing trains are approaching their meeting point. One train is running on time and the other has been considerably delayed and is several sidings away from the place of meeting. The train which has reached the carded meet attempts to call the dispatcher on the telephone, and the delayed train does likewise from the next or second next adjacent siding. Both find the telephone line to be in trouble. What is to be done? It is doubtless a fact that this condition is arising almost daily and is being handled without the least doubt in the minds of the train crews involved. The only thing to do, sanely or safely, is to go to the carded meet and wait there until the opposing train arrives, and no loophole is now provided in the rules whereby a man could construe his instructions to do otherwise.

Also consider a signaled railroad (this entire argument applies, of course, only to single track): the same two trains find themselves in the same positions as described above, under similar conditions, except that the delayed train finds a signal set against him two sidings in advance of his meeting point, while the signal for the opposing train which has arrived at the meet indicates proceed. We agree that it would be unwise to allow the last-mentioned train to consider the signal indication superior to his time-card and proceed. Why, then, should we unqualifiedly consider the stop signal indication as superior to the time-card to the utter demoralization of our train service?

The writer wishes to emphasize his unfailing regard for block signals and his belief that they must have the fullest attention and trust from the trainmen, but, at the same time, he believes that something can and should be done to recognize the difference in the present conditions from those existing in 1911.

JOHN LEISENRING,
Signal Engineer and Superintendent of Distribution.

Census Report on Electric Railways

The Bureau of the Census, Department of Commerce, has issued Bulletin No. 124, devoted to electric light and power stations and street and electric railways and giving the statistics of these properties for the year ended June 30, 1912. Some preliminary figures from this census report, so far as the street and electric railways are concerned, were published during the early part of the year. The tables contained in Bulletin 124 do not present all of the results which the bureau will issue. It is the intention to publish later a detailed report which will contain analytical text discussing the statistics and giving information in regard to the development of the industries. The present bulletin is published in order to distribute the important facts at an earlier date than they would be available if the publication was delayed until the final report is finished.

The statistics in regard to the electric railways cover fifty-five pages. The introduction says that an attempt has been made in the case of the electric railway companies to separate the income and investments from non-transportation activities, but this has not always been possible. A notable instance where the non-railway property was not separable from the railway property was that of the Hudson Terminal buildings of the Hudson and Manhattan Railroad in New York. The titles of the tables presented in the bulletin follow:

Tables 1, 2 and 3—Comparative summaries, 1912, 1907, 1902, for (1) commercial and municipal central electric stations combined, (2) commercial stations, and (3) municipal stations.

Table 4—Number of municipal central electric stations and increase, by geographic divisions: 1907 to 1912.

Table 5—Commercial electric stations, by character of ownership: 1912 and 1907.

Table 6—Comparative summary—Central electric stations and gas plants: 1912, 1907 and 1902.

Table 7—Central electric stations and electric railways—Number, kind and horsepower of primary power machines: 1912, 1907 and 1902.

Table 8—Commercial and municipal central electric stations—Number, kind, and horsepower of primary power machines: 1912, 1907 and 1902.

Table 9—Central stations and electric railways—Kilowatt capacity of dynamos: 1912, 1907 and 1902.

Table 10—Commercial and municipal central electric stations—Number, kind and kilowatt capacity of dynamos: 1912, 1907 and 1902.

Table 11—Central electric stations and electric railways—Output of generating stations: 1912, 1907 and 1902.

Table 12—Number of commercial and municipal central electric stations having no generating equipment, by geographic divisions: 1912.

Table 13—Central electric stations and stations operated in connection with electric railways—Line equipment: 1912, 1907 and 1902.

Table 14—Commercial and municipal central electric stations—Line equipment: 1912, 1907 and 1902.

Table 15—Comparative summary—Central electric stations and electric railways—Primary power, dynamo capacity, and output of stations, by geographic divisions and states: 1912 and 1907.

Table 16—Commercial companies—Capital stock, funded debt and dividends: 1912, 1907 and 1902.

Table 17—Summary for all central electric stations and hydroelectric stations reporting water power of 1,000 horsepower or more: 1912.

Table 18—Hydroelectric stations reporting water power of 1,000 horsepower or more, by geographic divisions and states: 1912.

Table 19—Commercial and municipal central electric stations—Comparative summary, by geographic divisions and states: 1912, 1907 and 1902.

Tables 20 and 21—Balance sheet—Assets and liabilities: 1912.

Tables 22, 23 and 32—Income.

Tables 24, 28 and 33—Expenses.

Tables 25, 29 and 34—Primary Power.

Tables 26, 30 and 35—Generating and subsidiary equipment.

Tables 27, 31 and 36—Line equipment.

Report of the Joint Committee on Inductive Interference

At the Pacific Coast meeting of the American Institute of Electrical Engineers held at Spokane, Wash., Sept. 9 to 11, A. H. Babcock, chairman of the sub-committee on publicity of the joint committee on inductive interference, presented a report which had been prepared for the Railroad Commission of the State of California. The organization and work of this committee has been described in the ELECTRIC RAILWAY JOURNAL in the issues of March 15 and Oct. 11, 1913, and Feb. 7, 1914. The complete report was transmitted to the Railroad Commission on July 7, 1914.

The report presents briefly an account of the formation of the committee, its activities and the results accomplished to date, together with recommendations for such rulings by the railroad commission as the committee believes are justified at this time, and included a technical discussion and explanation of the results and recommendations. The report gives a historical summary of the work of the committee which shows that it was the outgrowth of certain interferences involving power, communication and railroad interests which were brought to the attention of the Railroad Commission of Calfornia. The commission desired that the subject be thoroughly investigated before the general principles involved in the difficulties could be passed upon. To this end a general conference was called to select representatives to form the joint committee with power to conduct tests, experiments and investigations, the results of which would serve as a basis of recommendation. The conference was held Dec. 16, 1912, and the organization and personnel of the joint committee were approved on Jan. 6, 1913. Since this date the committee has been engaged in field work and in other investigations and has prepared a series of fifty technical reports which present and discuss in detail the various features of the work, the methods and apparatus employed and the results accomplished. A list of these is appended to the report.

The report deals practically altogether with interference to the operation of telephones, telegraph and signal circuits from power transmission lines, interference from single-phase railways being only incidentally mentioned.

The committee has determined from its experiments the following facts: 1. Interference in telephone circuits under normal operating conditions of power circuits arises almost wholly from the harmonic voltages and currents of the power system. 2. The effect of induction of the fundamental frequency on telephone circuits is comparatively unimportant unless it is of a magnitude sufficient to constitute a physical hazard. 3. Interference to telegraph and other signaling circuits is due principally to the fundamental and lower harmonics. 4. Power circuit currents and voltages may be divided into two factors, balanced and residual, of which, for equal magnitude, the latter in general produce the greater inductive interference. By "residual" is here meant the vector sum of the currents or voltages. 5. Inductive interference to communication circuits, rising from balanced voltages and currents, can in a large measure be prevented by means of an adequate system of transposition applied to both power and communication circuits, assuming that the latter are metallic and located with due regard to each other. 6. Abnormal conditions of line switching operations produce transient disturbances of a very serious character.

The committee recommends certain rules to be used as guides in connection with future construction and operation of power and communication circuits which are, or are proposed to be, so located as to create a "parallel." The term "parallel" here refers to sections where a power line and a communication line follow substantially the same course, or are otherwise in proximity for a sufficient distance, so that the power circuit is liable to create inductive interference in the communication circuit.

The rules are divided into these parts: avoidance of parallelism; conditions under which parallelism will be permitted; provisions applying to existing parallels; waiver conditions for a communication company, and parallelism with alternating current railways. These rules are discussed at length in the report. Appendixes to the report contain technical discussion on harmonics, balanced and residual voltages and currents, and transposition.

Under the heading "parallelism with alternating current railways" the report states that it is recognized that railroads operating alternating current trolleys with ground return create serious inductive interference with parallel communication circuits. In the present state of the art, no means for completely overcoming inductive interference from such parallels is known, hence, they are to be avoided if possible, and where unavoidable, responsibilities arising therefrom must be settled by mutual agreement, or in case of inability to agree the matter shall be referred to the Railroad Commission of the State of California.

Since the Topeka (Kan.) Street Railway moved a bandstand to Gage Park, gave it and 300 benches to the city, and paid a band for a public concert in the park, the city is considering giving concerts there.

Equipment and Its Maintenance

Short Descriptions of Labor, Mechanical and Electrical
Practices in Every Department of Electric Railroading

(Contributions from the Men in the Field Are Solicited and Will be Paid for at Special Rates.)

Overhead Problems—Catenary Construction—II

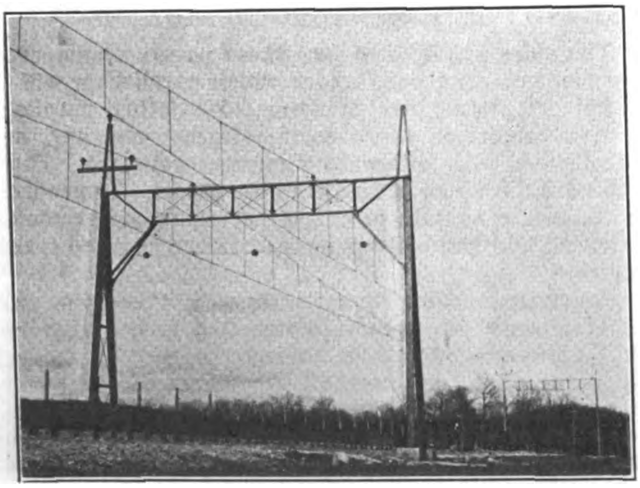
BY CHARLES RUFUS HARTE, CONSTRUCTION ENGINEER THE CONNECTICUT COMPANY

An almost infinite variety of hangers has been tried but very few of the forms have persisted, the majority either taking too much time to install or shaking loose in service, not a few doing both. That which seems to meet conditions best is a mechanical three-screw clip rigidly attached to a steel strap, the top of which is formed into a loop 3 in. or 4 in. long, permitting the contact wire to rise to that extent. The other types, with all sorts of cam, screw, toggle, wedge and what-not locking devices, many of them exceedingly ingenious, are for the most part of interest only as a matter of history. Early forms of strap hangers were hinged at the lower end, but this permitted the loop to tip over, and with each lift to crawl further out on the messenger until all the lift was taken up and the flexibility lost.

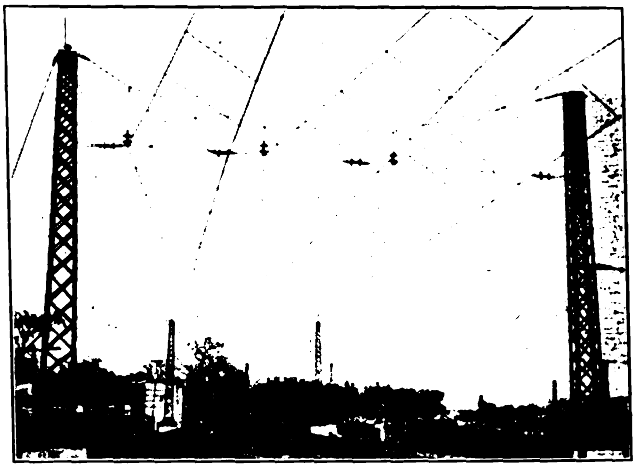
To facilitate installation several ingenious ways of making the loop have been devised. In one the end is twisted back of the main stem, leaving a space of such shape that the hanger screws on to the messenger; another snaps into place, the spring of the shaft normally keeping the loop closed; while a third, also of the snap type, has the tail of the strap so bent up inside the loop that, once snapped on, the messenger cannot get into a position to wedge its way out.

COMPENSATION FOR TEMPERATURE CHANGES

Changes in temperature tend to cause corresponding length changes in the various members of catenary construction, but the actual result is largely affected by the character of the construction. The messenger, contracting or expanding, tends to lower or rise, the movement being a maximum at mid-span, and zero at supports; the contact wire tends to do likewise, but at a different rate because of its different sag. The hangers tie the two together and compel equal movement, giving to the contact wire in cold weather an inverted sag, so to speak, and in hot weather slack wire between the hangers.



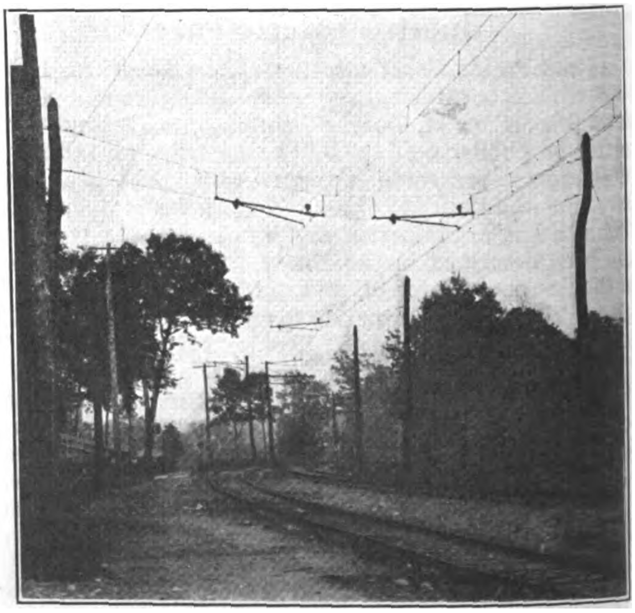
CATENARY CONSTRUCTION—LIGHT BRIDGE, SYRACUSE, LAKE SHORE & NORTHERN RAILWAY



Note the Murray curve hangers, and the smooth line obtained.

CATENARY CONSTRUCTION—NEW HAVEN SPAN SUPPORT

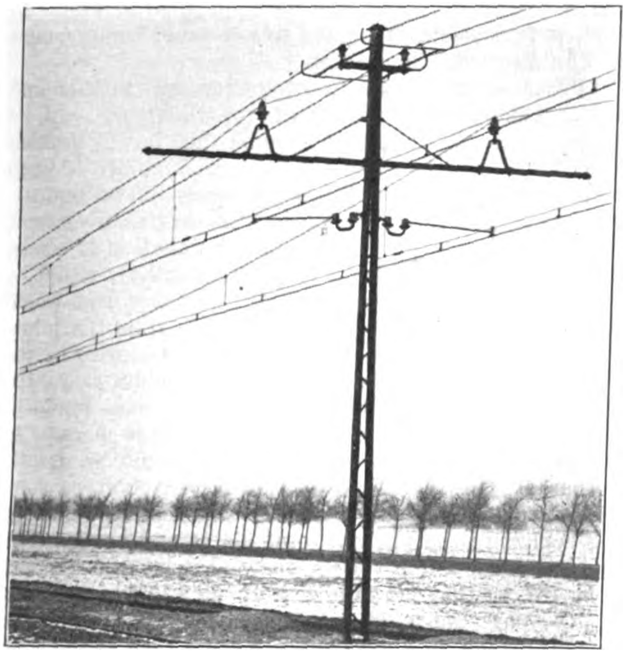
On the Syracuse, Lake Shore & Northern Railway, which was erected in winter, the contact wire was given a very high initial tension and an inverted sag of 1 ft. to the standard 300-ft. span, so that the heavy summer traffic should have a fairly tight straight line. With this one exception, which, it is said, did not entirely meet expectations in this respect, American engineers have considered compensation devices not worth the complication, a belief well justified by the behavior of the lines which are in service without such devices.



CATENARY CONSTRUCTION—SPAN WITH STRUCTURAL MEMBERS CARRYING INSULATOR AND STEADY BRACE

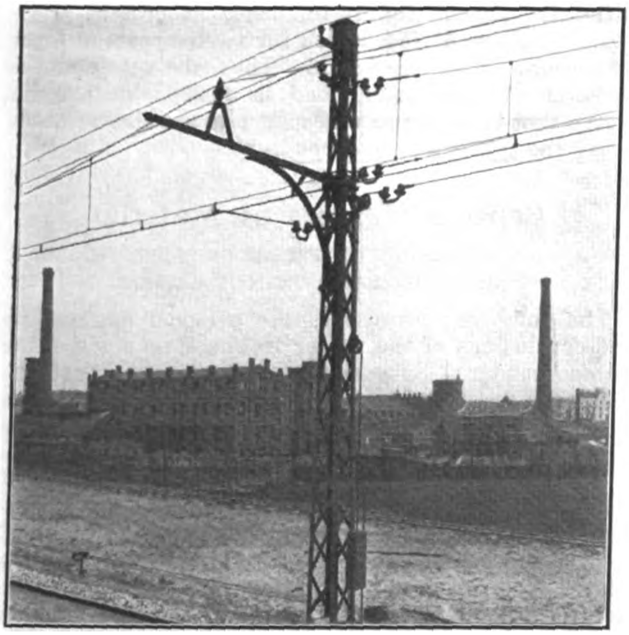
Abroad, however, compensators are almost universally employed. The Siemens-Schuckert device is a weight of about 1200 lb. sliding in or on an ornamental post. The contact wire, approximately No. 000 in section, in lengths of about 3200 ft., has one end anchored while the other is attached, through insulators, to the weight. Although an engineer some years ago proved—on paper—before the American Society of Civil Engineers that unless sheaves more than 25 ft. in diameter were used the effort of bending the wire around the wheel would balance the weight, the use of such compensators is still persisted in by many foreign engineers. By carrying the ends of adjacent sections by each other with a lateral separation of a few inches, they are insulated from each other, except as the collector bridges both as it passes, without a break in the smoothness of the contact surface. The ends are then raised slightly to prevent fouling and are carried to the weights or to anchors. The clips looped over the secondary messenger permit the necessary longitudinal movement of the contact wire. Fear that these loops might bind has developed the Fischer-Jellinek form with loosely gripping ears, through which the contact wire is free to slide.

Weight compensators prevent wide variations in the tension of the contact wire, but also relieve the messenger of the pull in cold weather of the contracting contact wire. Further, the lift at the span center is correspondingly increased, giving a very wavy line. The Allgemeine Elektricitäts Gesellschaft overcomes this by stringing above the messenger and tighter than the latter an equalizer wire which hangs free except for an indirect attachment to the support by a short cable, and the direct attachment of the end to the contact wire, under the support. A temperature drop which shortens the messenger and so lifts the contact wire at mid-span also shortens the equalizer, and through the cable connections lifts correspondingly at the supports.



Note two clips between each pair of main hangers.

CATENARY CONSTRUCTION—BRACKET SUPPORT, ROTTERDAM-HAGUE LINE DOUBLE-TRACK CENTER-POLE CONSTRUCTION



The next pole to the right is also a compensator, taking care of the wire which is seen passing the compensator shown.

CATENARY CONSTRUCTION—COMPENSATING POINT ON BLANKENESE-HAMBURG-OHLSDORF LINE

The Return Circuit—Ultimate Economy of Longer Bonds

BY HOWARD H. GEORGE, ASSISTANT ENGINEER MAINTENANCE OF WAY, PUBLIC SERVICE RAILWAY, NEWARK, N. J.

The terms "longer" and "shorter" are, of course, only relative, but in this discussion an 8-in. bond will be considered as short and a 36-in. bond as long. It is admitted that under like conditions the amount of energy loss will be greater for longer than for shorter bonds. For this reason, if the joints are to be maintained perfectly the advantage of the short bond will be evident, yet one poorly-bonded joint may cause an energy loss greater than that in the remainder of an entire mile of track without visible evidence of the defective bonding.

Suppose we assume a 10-mile line of single track constructed with 80-lb. 30-ft. rails having a ratio of conductivity of 1:12. With a permissible track loss of 3.5 volts per 100 amp-mile (14 volts per mile for average current of 400 amp), the total resistance per mile would equal $\frac{3.5}{100}$, or 0.035 ohm per mile of single track, or 0.070 ohm per mile of rail. From our tables we find that the resistance of our rail is 0.065757 ohm per mile.

Total rail and joint resistance	0.070000 ohm
Resistance of rail only	0.065757 ohm
Resistance of 170 joints only	0.004243 ohm

Referring again to our tables, we find

Resistance of 170 No. 0000 10-in. bonds	0.0077401 ohm
Plus 4 in. x 0.00000410 ohm per inch	0.0000164 ohm
Resistance of 170 14-in. No. 0000 bonds	0.0077565 ohm

This is larger than our permissible resistance, so again referring to our tables we see that

Resistance of 170 500,000 circ.-mil 10-in. bonds	0.003740000 ohm
Plus 6 in. x 0.000001782 ohm per inch	0.000010692 ohm
Resistance of 170 16-in. 500,000 circ.-mil bonds	0.003750692 ohm

This is within our limit, so that we could either bond with a single 500,000 cir.-mil bond, or with two No. 0000 bonds.

Resistance of rail only	0.065757 ohm
Resistance of 170 16-in. 500,000 circ.-mil bonds	0.003751 ohm
Total resistance per mile	0.069508 ohm
Total resistance per mile of two rails	0.034754 ohm

Continuing the discussion still farther, suppose we assume a 400 amp current (average) for twenty hours per day. The track resistance for the 10 miles would be 0.347 ohm.

Energy loss = $I^2 R = 400^2 \times .347 = 55{,}520$ watts.
Twenty hr. per day × 365 days = 7300 hr. a year.
55.52 kw × 7300 hr. = 405,296 kw-hr. a year.
405,296 kw-hr. × 1 cent = $4,052.96 a year for the 10 miles.

Upon the same basis of figuring an increase in the track loss of 1 volt per 100 amp-mile would mean an increase in the financial loss of more than $1,000 a year. When it is considered that many systems cover hundreds of miles of track, the importance and relative economy of close attention to the conditions of the return circuit will be realized.

The assertion has already been made that the increased life and efficiency of the longer bond will generally more than offset the increased cost of the copper. Keeping in mind the relations which should exist between the proper length and cross-section, the reader will note by reference to the second of the series of articles of this subject that the maximum length mentioned for a 500,000 circ.-mil bond was 18 in. It is apparent at once that a bond of such a length must be installed under the plates and therefore it offers no inducement to copper thieves.

As an illustration of the effect of an increase in the length of a bond on its life, it will be interesting to refer to a series of tests made by one of the rail bond makers, where many two-conductor pin terminal stranded wire bonds of varying lengths, but all of No. 0000 capacity, were tested to destruction in the same vibration machine. These tests should prove in a most convincing way the advantages of longer over shorter bonds, since the principal cause of failure of bonds, assuming that they have been properly installed, is the play of the rail ends where the joints are loose. The following are the results:—

7-in. bonds broke at 41,000 vibrations
8-in. bonds broke at 215,000 vibrations
10-in. bonds broke at 1,279,000 vibrations
14-in. bonds broke at 7,887,000 vibrations

In other words, the 14-in. bond withstood approximately 6.2 times as many vibrations as the 10-in. bond before failure; 36.7 times as many as the 8-in. bond, and 192.4 times as many as the 7-in. bond. To be sure, these tests were made in a laboratory and not under service conditions, but they do give a fair indication of the relative life on the basis of length.

As to increased resistance from longer bonds, the resistance of No. 0000 bare copper strand per 1000 lineal feet at 68 deg. Fahr. (taken from table) is 0.04997 ohm, or 0.000004164 ohm per lineal inch. Therefore, the resistance of the various lengths of bonds used in the tests referred to, neglecting the contact resistances which we can assume to be the same for all lengths, would be as follows:—

Length of Bond	Resistance
7-in.	0.000029148 ohm
8-in.	0.000033312 ohm
10-in.	0.000041640 ohm
14-in.	0.000058296 ohm

If we return to the case of a single track road 10 miles long and laid with 30-ft. rails, we would have 3520 joints. If 14-in. bonds were installed, the resistance of the joints would be increased 0.08794 ohm, compared with 8-in. bonds. If we assume 80 lb. per yard as the weight of the rail, the resistance of the steel (neglecting the joints) would be 0.328785 ohm. The total joint resistance of 3520 joints bonded with 8-in. bonds (again neglecting the contact resistance) would be approximately 0.131406 ohm, or a total resistance of 0.460186 ohm for the return circuit. As shown above, the increased resistance, if 14-in. bonds were used, would be 0.08794 ohm, or an increase in the resistance of the entire return circuit of about 19 per cent. This may seem like a very large percentage, but if the 8-in. bonds were used, since the joints are not liable to be maintained perfectly tight all the time, the life of the short bonds will be only about 1/37 of that of the 14-in. bonds, thus quickly decreasing their efficiency and increasing the total resistance of the return circuit to much more than if the 14-in. bonds had been installed at first. In short, it is a waste of money to use short bonds where the joints are not kept tight.

Suppose we carry the investigation still farther and assume that the estimated life of the track will be twelve years. We will also assume that it was decided to install 8-in. bonds and that the efficient life of such bonds would be six years (an extremely liberal figure). Based upon present market prices the initial investment (not including the cost of original installation of bonds, which would be the same for both lengths), would be about $1,334, which for six years at 6 per cent would amount to $1,815. At the end of this time the joints must be rebonded, and assuming that the price of the bonds has remained the same during the six years, the total cost of the 8-in. bonds for twelve years would be $3,630. To this should be added a charge of, say, $1 per joint (also a fair figure, which would be greatly increased if the paving were brick, asphalt or some other expensive type), to cover the cost of removing and replacing the paving, joint plates and bonds. This equals $3,520, which for six years at 6 per cent amounts to $4,787, so that the total cost of the 8-in. bonds for the twelve years has been increased to $8,418. From this we will deduct an allowance of 5 cents each as the scrap copper value of the first set of bonds, amounting to $176, leaving the net cost of the 8-in. bonds at $8,242.

If the 8-in. bonds were good for six years, it is reasonable to conclude from the tests noted that 14-in. bonds would be good for the entire life of the track. The initial investment for 14-in. bonds at present prices would be about $1,754, which for twelve years at 6 per cent would amount to $3,016. Thus, the net difference in favor of the longer bond is $5,226, which again proves that "it is a waste of money to use shorter bonds where the joints are not kept tight."

Centers—Classes of Material

BY R. P. WILLIAMS, INSPECTOR OF SPECIAL WORK
BROOKLYN RAPID TRANSIT SYSTEM

The following represents the personal observations and conclusions of the writer from a close study of the service rendered by various types of centers, and the matter is presented in an effort to aid all the interests concerned toward a correct solution of the problems discussed.

The growing dissatisfaction at the performance of "hard center" work after twenty years of use is worthy of serious consideration. Perhaps the practical experience of one who has followed the "wearing plate" from its first installation, may be of service in determining such points as the following: Whether the fault is in the material used in the insert, or in the method used to retain or remove it; whether the renewable feature is worth while; what bearing the shape has with regard to the life of the center, and whether it may or may not be possible that most of the dissatisfaction arises from grooves of improper depth and width.

The first center used was a block of Bessemer steel 14 in. x 9 in. x 4½ in., set in an opening a trifle larger than itself, provided in a cast-steel frog, with no provision for retaining it other than a few shims driven in about the sides. The idea was that as the top surface became worn the block could be removed, resurfaced and reset. This was found to be impracticable because the wear on the sides and bottom was so great as to destroy the retaining box. This was replaced by the first really renewable center, made also of soft steel, but case-hardened on the wearing surface by the old English method. In this process a band of hoop iron was placed around the center to make it stand ¾ in. higher than the top of the piece. The combination was filled with bits of leather, horse hoofs, etc., placed in a furnace, heated to the required temperature, withdrawn and plunged into cold water. By this method the temper of the piece could be so graded that the part receiving the impact of the wheel in crossing the groove could be made much harder than the ends which abutted the rails of the frog.

It has been the writer's experience that centers made according to the old English method have given greater satisfaction than any others, and they are the only centers he has known to last as long as the crossing with which they were furnished. When this center became dished it could be removed, the ends ground to a surface level with the lowest part of the center and reset; and it would last longer in the second setting than the first. This tends to prove that the softer metal under the case-hardened surface acted as a shock absorber. This type of center rarely chipped, never cambered from cold rolling and the secondary pound or lamination of the abutting rail end was seldom seen in connection with it.

We have a great number of so-called "case-hardened" centers, but they must not be considered in the same class as the ones first described. These centers are treated in an entirely different manner. A harder steel is used for the stock, and after the planing and fitting has been completed the center is heated to a white heat; then potash is sprinkled or dusted on the top, and when the potash melts or liquefies the center is plunged in cold water. Within a few hours after their removal the writer has known such centers to chip or spall without being touched. He has also known many cases where for the same reason new centers had to be used after the pieces had been finished in the factory and were ready for shipment.

Now as to the all-hard or manganese center. If you reverse the criticism of the original case-hardened or Harveyized center, you have a fairly accurate description of the manganese center under service. This is especially the case in 90 deg. or nearly 90 deg. crossings, for in the frogs of branch-off curves, when the radius is 60 ft. or more, they wear well; but in the shorter radius curves, say between 30 ft. and 45 ft., the dishing or gouging out of the gage lines and guards between and abutting centers is very marked. Instances where derailments are caused from this side wear are quite numerous. We have a case in view now where a curved crossing must be renewed at least two years before its time, according to the life still left in the abutting rails of the curve which have the same radius as the crossing.

From the foregoing it would seem that centers which are all hard, or of one grade of hardness, cannot be used in all cases. We have experimented along this line and have demonstrated that the hard center under extremely heavy traffic ruins more special work than it saves; also that with a soft center under moderate traffic there is more possibility of getting the full value of wear out of 90-deg. crossings than by the use of hard material.

More crossings are removed because of noise complaints than on account of actual wear to the crossing. To illustrate, we have a certain crossing under moderate traffic (950 cars per twenty-four hours). An examination showed that all of its sixteen hard centers were dished at the intersections and that half of them were chipped also. Eight of the manganese centers were replaced in one run by eight open-hearth steel forged centers, while eight of the manganese centers were straightened and surfaced for re-use in the other run. Both runs had the same traffic. An examination made sixteen months later showed all of the soft centers to be tight, practically noiseless and in good order, with little evidence of wear. Of the eight hard centers only one had remained tight, five of the total number were chipped, while the noisy condition of all was very noticeable. Every hard center was then removed and replaced with open-hearth forged centers. The estimated life of the forged centers is six years, a saving of four and one-half years compared with manganese. Evidently this experience demonstrated that a grading of the material to suit the conditions of traffic is necessary.

Coil Room Practice

BY A MISSOURI CONTRIBUTOR

A number of companies complete their coils, that is to say, they give them the last dipping and baking, and then store them. In this way they are liable to accumulate a large number of sets which become hard, and as the first sets made are the ones which are given out the winders always have hard coils to work with. It has been the writer's experience in winding with hard coils that they do not lie together as they should, because the forming thus made necessary is a disadvantage which causes trouble with hard coils. Further, in banding armatures, non-flexible coils do not draw together tight unless they are banded hot. But if the coils are very old such heating will do little good. Another bad practice is the excessive baking of coils. When they are in service they will get baking enough. However, my main point is that the final dipping and baking should be left until the day before the coils are to be used in order that soft coils to work with will always be available. Accumulate as many sets of coils ahead as you want to, but postpone the final dipping and baking. When you need any see to it on the night before that the desired number are dipped and put into the oven ready for use the next day.

I would suggest the following course in the making of coils: No coil should be passed with the smallest kind of a kink in the wire, as this is liable to cause a short-circuit. Watch out also for welds in the wire. Coils should be held together with small flat clips of lead. It is bad practice to use small tie wires because they are overlooked, thus causing trouble after the armature is wound. After the coils are wound they should be dipped and left in the oven over night. Then the leads should be tinned to insure good connections to the commutator. In assembling coils, if three coils are used the middle coil should be taped all around, if possible. If not, paper insulation should be inserted between the parts of the coil that fit in the slot. When the coils are being assembled and tied, tubing should be slipped on the leads and the coils should be assembled and tied with fine flax thread. They are then ready to be taped with Empire bias tape at about half a lap on the taping machine. Next they are ready to be taped all around with about ¾-in. linen tape at about half a lap, stored away and left for the final dipping and baking during the night before use. In conclusion, railways should be careful about using home-made coil winding machines when so many good ones are available from the manufacturers of such tools.

Weights and Grades of Railings and Other Car Piping

BY R. H. PARSONS, ELECTRICAL FOREMAN

In these days when so much attention is given to all the details of car equipment to the end that unnecessary weight may be eliminated, it is of interest to offer the results of a railing study recently made in this connection on a number of prepayment cars. All of the railings and fittings illustrated are made from 1-in. galvanized piping except for the main stanchion of the pay-within car, which is of gray iron. It was found that in the pay-within type of car the total weight of the fixtures illustrated, comprising the conductor's control and fare-box stanchion, weighed a total of 104¼ lb. On the first of three earlier types of prepayment cars with a dividing rail and support for the fare box the total weight was 59 lb., on the second, 68 lb., and on the third 78 lb.

The old type railings were made of 1-in. galvanized pipe which cost $0.046 per foot. This is the most suitable material for strength, appearance, adaptability for bending and freedom from rust. As the pipe is held to the floor by flanges screwed to the pipe and by special castings, including those used for holding the fare box, it would not be advisable to lighten the same grades of material because good stock is needed to hold the fittings. Such fittings must be strong enough to bear the

weight of the conductor when he is tired and to withstand the violent movements of passengers who want to steady themselves at the starting or stopping of the car. The stanchion for pay-within cars must be especially strong, as it has no support from the floor up to its full height. On this stanchion rests the burden of making a fulcrum by means of which the doors are opened and closed.

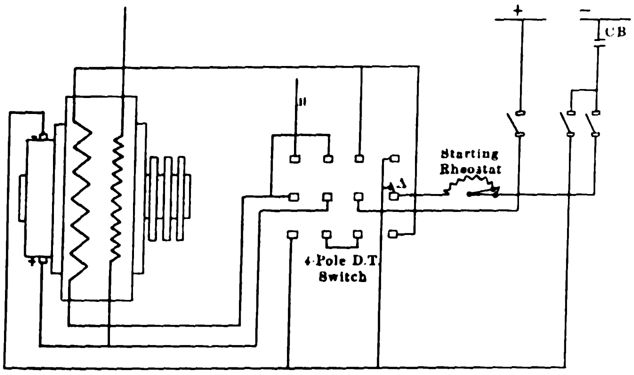
The Flexibility of Rotary Converters

BY T. A. LEES, DEPARTMENT OF MOTIVE POWER AND MACHINERY, BAY STATE STREET RAILWAY

In generator or motor practice no machine offers such flexible operation as the rotary converter.

In one of our larger d.c. plants we also supply a small alternating system. For this service we have a 400-kw rotary operating inverted from the d.c. busbars. A few years ago the a.c. load was increased by an additional service and an 800-kw alternator was installed. This service was later abandoned and therefore the inverted rotary could again take care of its former service.

In order to utilize the 800-kw unit, which is an efficient machine, we have arranged the wiring of the inverted machine so that it may be used as a regular converter and supply power to the d.c. service. During the peak hours or other heavy periods the alternator is run and serves the a.c. system and, through the converter, also feeds into the d.c. system. It was formerly necessary to start another large unit during these periods which are now easily taken care of by the converter.



Note—A is a contact which prevents opening of the shunt field circuit while changing position of main switch

Switch up when Converter
Switch down when Inverted

Electric Ry. Journal

SKETCH SHOWING WIRING OF MACHINE USED AS PLAIN AND INVERTED ROTARY CONVERTER

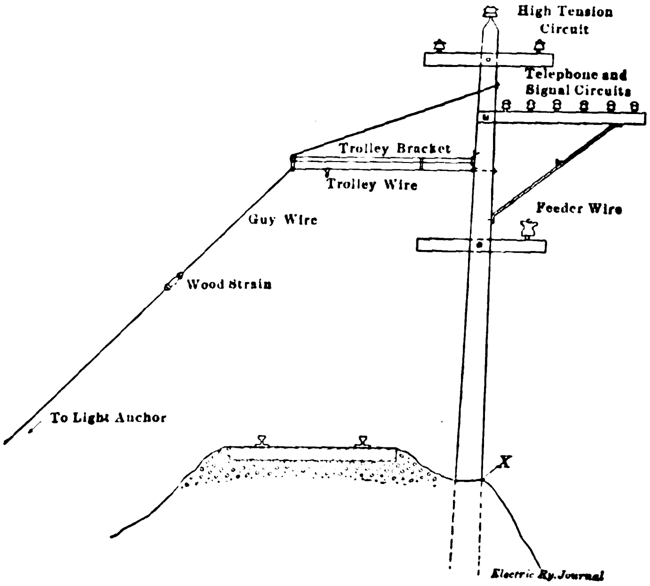
While converters have been floated between a.c. and d.c. systems on other installations the connections of this installation are unusual. The converter is arranged for d.c. starting only and therefore is started as a compound motor with the series field on the negative side. After the machine is up to speed the series field is opened and the machine then is run as a shunt inverted converter in order to give proper speed control. The rotary then feeds into the a.c. service through step-up transformers to a potential of 5500 volts.

The alternator generates 5500 volts and is phased in on the regular buses. To change from an inverted converter to a regular converter the d.c. side is disconnected and a double-throw switch is thrown, with changes the connections of the machine to a regular compound converter with the series field now on the positive side. The entire change is made in a moment by simply throwing this switch up or down with the converter running from the a.c. side. The accompanying sketch shows the connections that were necessary to obtain this flexibility of operation.

The same plant also contains another interesting unit which is somewhat flexible in its uses. It is a 400-kw engine-driven double-current generator which in reality is an engine-driven rotary converter. This unit is sometimes operated as an alternator or as a d.c. generator, and occasionally it has served both systems at the same time. It has also been equipped with an extra series field coil so arranged that in times of necessity the machine is run as a series line booster on one of the long feeders.

Maintaining Alignment of Poles

Practically every line foreman can recall a group of poles with which he has had trouble on account of their seeming persistence in getting out of alignment. In most of these cases the setting of the poles has been done improperly or the character of the soil is such as to prohibit satisfactory pole line installation. A typical instance of such a pole line is shown in the accompanying sketch, the poles here carrying high-tension, trolley and auxiliary circuits, and being set too near the edge of the embankment to insure stable conditions. As the earth behind the pole becomes soft in wet weather the pole has a tendency to lean away from the track, for as vibration at right angles to the line is set up by winds or passing cars the earth at *X* offers little resistance in a longitudinal direction, while that on the opposite side of the pole gives very little. After such a pole has once settled to the right from its perpendicular position its own weight tends to aggravate the trouble.



Electric Ry. Journal

GUY WIRE AND ANCHOR FOR MAINTAINING ALIGNMENT OF POLES

To correct this condition a transmission and electric railway company in northern Illinois has adopted the expedient of attaching a guy wire to the end of the mast arm and to a light anchor of some type quickly and cheaply installed. With this wire drawn taut while the pole stands upright no difficulty is experienced in keeping the poles in line and the line is given an added factor of safety against wind.

The bureau of mines of the Department of the Interior has recently issued a preliminary report, known as Technical Paper No. 63, based on investigations made on the subject of factors governing the combustion of coal in boiler furnaces.

LIBRARY OF THE UNIVERSITY OF

New San Francisco Municipal Railway Cars with Mechanical Reverser Throw

The Van Ness Avenue and Chestnut Street extension of the San Francisco Municipal Railway was completed on Aug. 4, the contractors thereby earning the maximum bonus of $15,000 for completion ahead of schedule. Regular service on the new line, which is designed primarily to handle traffic to the exposition grounds, was commenced on Aug. 15 with seventeen of the new cars just received from the factory. A total of 125 of these cars have been ordered, and they are now being delivered in San Francisco at the rate of twenty-five per month. As fast as received they are being assembled and substituted for the old cars on the Geary Street line. The old cars will not be put back in service until the increase in traffic to the exposition requires their use.

The new cars are of the California type, with semi-steel construction, and are finished in three-ply veneer. In order to increase the carrying capacity the inclosed section has longitudinal seats, but the car frame is fitted with lugs for cross-seats, which it is the intention to install when the rush of exposition traffic is over. The drop platforms on each end are ramped toward the sides to insure drainage in wet weather, and the center aisle is depressed for the use of steel mats to be flush with the remainder of the floor. The light wiring is run in open conduits, a Crouse-Hinds condulet being provided for each lamp outlet, so that all wiring is accessible for repair. A switchboard mounted directly over the motorman's station at each end of the car carries the terminals of all buzzer signal lamp and pump circuits.

The electrical equipment includes Westinghouse 306-CA 50-60-hp motors with a gear ratio of 15:69 and HL control. This control, however, is not the original HL type, as it includes means to give the motorman absolute control of the car regardless of air pressure or energy supply. To accomplish this the reverser is connected by means of levers and flexible wire rope to a handle at the motorman's station at either end of the car. In case of failure of current, with defective brakes, the operation of this handle throws the reverser so that the motors are utilized for braking power. This emergency device is interlocked with the control circuit so that in the normal position the current is fed through interlocking fingers to the controllers. When the reverser is operated mechanically from the platform it opens the interlock fingers and breaks the control circuit. Thus a car can be reversed without throwing the controller to the off position. The chief advantage of the interlocking, however, is that it prevents the accidental burning and blistering of the reverser contacts by making it necessary for the motorman to bring the car to a full stop, leave the platform, and reset the interlock fingers and the reverser at the side of the car before the master controller is again effective for its regular duties.

Other features of the control equipment are the two conductor's valves used in connection with Westinghouse type H emergency valves. The conductor's valves, which are arranged to be operated from either platform, connect the main reservoir with the brake cylinder, and at the same time operate the air sanders. A break in the pipe lines on either end of the car has the same effect as opening the conductor's valve.

The new cars were built by the Jewett Car Company. T. A. Cashin is superintendent of the San Francisco Municipal Railway, and the cars are being assembled under the supervision of William C. Bendel, master mechanic.

Home-Made Crew Signaling Device of Bangor Railway & Electric Company

A convenient device for calling car crews and inspectors to the telephone is used by the Bangor (Maine) Railway & Electric Company. It is illustrated in the accompanying halftone and wiring diagram, and consists of a pole box at each end of the line section covered, the box containing three 16-cp incandescent lamps wired in series and installed behind red bull's-eyes mounted on three sides of the box, so that when the lamps are lighted the attention of the desired employee will be more readily attracted. At each box is a spring switch of the single-pole, double-throw type. The two boxes are connected in series, and energy for the operation of the lamps is derived from the local trolley circuit. The switch in each box is always on one contact or the other, and the wiring is so arranged that when the movement of the other switch from one contact to the other throws a current through the six lamps the inspector or car crew is called to a telephone located in the box. One switch contact in each box is connected to the trolley and the other to ground, and it is impossible for the switch to short-circuit the line. In times of irregular car service over the single-track line thus equipped it is often a great convenience to be able to call up the car crew or the downtown inspector after a car has entered the section concerned, and to give orders or find out the situation regarding the prospective movement of traffic.

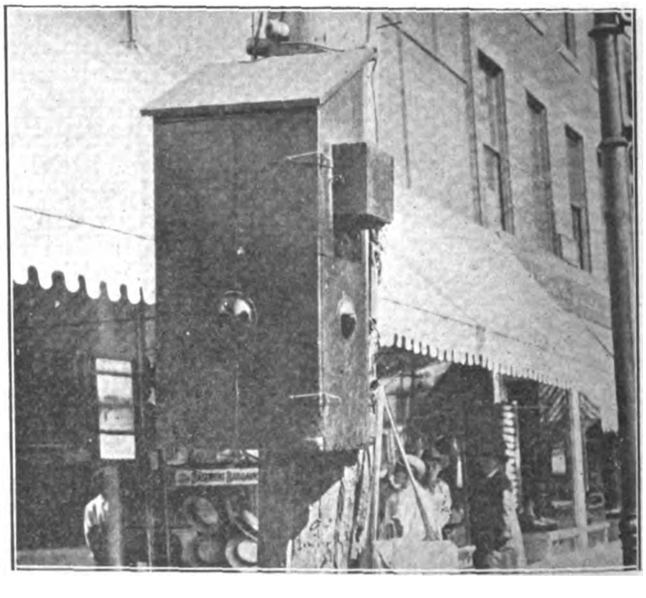
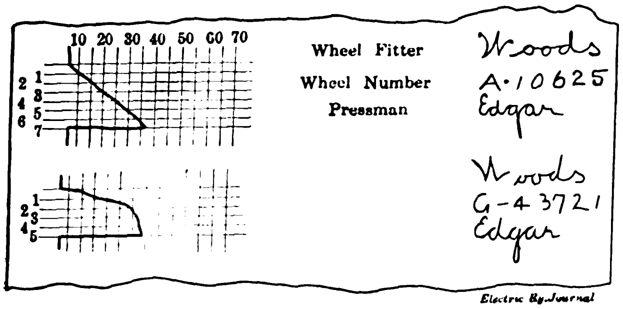
HOME-MADE SIGNAL OF THE BANGOR (MAINE) RAILWAY & ELECTRIC COMPANY



SIGNAL BOX OF THE BANGOR (MAINE) RAILWAY & ELECTRIC COMPANY AS INSTALLED ON A STREET POLE

Wheel Press Recording Gage

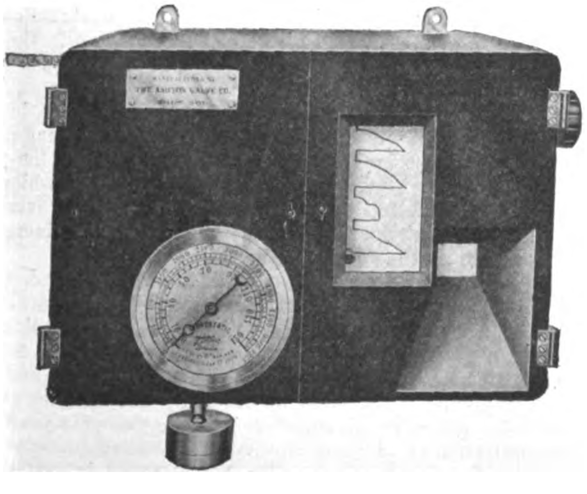
The possibilities for securing exact results in electric railway shopwork are demonstrated again by the use of gages to insure the perfect mounting of wheels on axles. These gages give a graphic story of how the work was done, disclosing immediately such defects as improperly finished axles, loose wheels and excess pressures. The gage made for these purposes by the Ashton Valve Company, Boston and Chicago, is shown in one of the accompanying cuts, and sample records of good and bad work are shown in another view. The upper curve shows a perfect wheel fit for 5⅛-in. bore, hub 7 ft. long, with 7 tons pressure per inch of bore applied gradually in proportion to the travel of the wheel on the axle. The lower curve shows a bad wheel fit because a 30-ton pressure was applied for the first 1½ in. of fit leaving only 7 tons additional pressure for the remaining 3½ in. so that the wheel fits only on the side of the hub first forced on the axle.



Electric Ry. Journal

TYPICAL RECORDS OF GOOD AND BAD WHEEL FITS

The graphic gage is the combination of a hydraulic pressure gage and a recording device. The latter operates automatically in conjunction with the former, furnishing on a continuous record roll a diagram of each pressure application and means for registering opposite each diagram such information as may be desired to identify the wheel number, fitter and pressman. The record roll has a capacity of 300 diagrams, or 150 pairs of wheels. It can be readily removed for filing when complete, and a new roll inserted without any appreciable loss of time.



WHEEL PRESSURE RECORDING GAGE

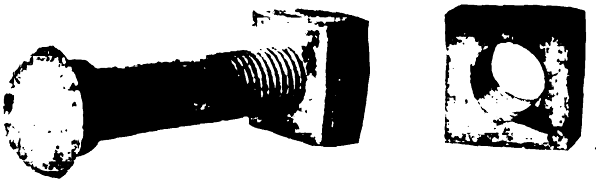
Included with the equipment of each gage are the following accessories:

A ⅜-in. hydraulic relief valve to protect the machine from any excessive over-pressure; a ½-in. pulsating check valve to protect the gage spring and both the registering and recording hands from sudden fluctuations in pressure; a ½-in. lock-up stop cock to be used as a shut-off when demounting wheels; a graduated scale with which each diagram can be measured for both the length of the fit in inches and the pressure at each corresponding point in tons on ram. Each 1/16-in. open space in vertical base line of the diagram represents a 1-in. length of fit on the axle. The pressure record is measured horizontally from the readings on the scale; instruction data.

This gage can be adapted for use on any single ram wheel press, provided the diameter of the ram is known. All gages are graduated to a maximum of 150 tons pressure unless otherwise specified.

Pawl and Ratchet Principle Self-Locking Nut

By taking advantage of the pawl and ratchet principle, and applying it to an ordinary nut and bolt, the Daniel Safety Device Company, Chicago, Ill., has recently put on the market a new type of self-locking nut. The application of the pawl and ratchet principle to the nut is quite simple and embraces a spring steel pawl swedged into a pocket pressed into the nut when it is made. As shown in the accompanying illustration, this pawl occupies only a portion of the nut depth, and its size is varied so that it may be applied to any nut, from the smallest to the largest.



SELF-LOCKING NUTS, SEPARATE AND APPLIED

The angle of the pawl to the thread is such that as the nut is turned onto the bolt the pawl rides freely on the bolt threads. If an attempt is made to reverse the nut the sharp edge of the pawl immediately bites into the bolt thread, thus effectively locking the nut against loosening. Vibration acts only to tighten the nut, since a reverse movement merely causes the pawl to cut a deeper recess for itself in the thread. In actual service it has been found that when a bolt stretches, vibration tends to cause this nut to take up the extra length.

The "Bulldog" self-locking nut, as this pattern has been named, is made in several types. Thus the type for trackwork is not provided with an arrangement for releasing the pawl, since it was believed that few trackmen take the time to unscrew a nut when it is necessary to remove an angle-bar. However, if it is desired to make provision for unlocking the nut, the pawl may be set on the outside of the nut instead of the inside, in which position the pawl may be released by inserting a nail behind it. For high-grade machine work the same principle is employed but the pawl is set in a pocket on the inside of the nut. This pocket, however, is pierced by a hole from the face of the nut to permit the insertion of an unlocking key. Besides serving as a lock, the pawl also prevents anyone from applying the nut in the wrong position. If the back and the base of the nut are reversed, the pawl engages with the threads as it is turned onto the nut.

The electric railway mail cars formerly used by the Post-office Department in Brooklyn, N. Y., have been supplanted by twelve automobile trucks.

News of Electric Railways

HAZLETON STRIKE SETTLEMENT

Company Issues Statement to Public Giving Facts in Regard to Terms

In order to make the position of the company clear with reference to the declaring off of the strike of employees, Alvan Markle, president of the Lehigh Traction Company, Hazleton, Pa., issued the following statement to the public on Aug. 24:

"It was the hope of the Lehigh Traction Company, when the strike was officially declared off, that the public announcement of the fact would not be accompanied by any declaration that might tend, in the slightest degree to complicate the present status or future relations between the company and its employees. Our hope has not been realized. The statement published in the press and the inferences drawn therefrom by the press and public are quite misleading. They give rise to a false impression concerning the status of the recent striking employees with the company and its obligations to them.

"If these statements were persisted in and these false impressions permitted to remain, they would only serve to confuse and complicate the future and become the subject of renewed strife. For that reason this statement is issued and we hope it will be the last.

"When Mr. Colgan sought on Aug. 17 to learn the attitude of the Lehigh Traction Company toward the men on strike, we informed him it was fully expressed in our public statement of July 16 and particularly by the following paragraph:

"'We say to you, our former employees, that there are vacancies open to a considerable number upon the lines of the Lehigh Traction Company. We say to every one of you who is worthy of confidence that we will be glad to receive your application and place you at work as soon as the circumstances warrant. No one will be discriminated against because of union affiliations. . . . We regret that all worthy employees cannot be taken back at this time. We cannot repudiate our existing contracts with our present employees. . . .'

"We stated to Mr. Colgan at that time that this was still our position. To him and to others who came we repeated it. And the last authoritative utterance that came from this company upon the subject to him and all others was this: 'We stand to-day in that position. We will neither advance nor recede from it.'

"This statement now governs this company in meeting the present conditions and will continue to control its action in the future. At no time did this company agree to the statement that 'all men except three will be given employment.'

"It will carry the above out generously in letter and spirit. But it has not agreed to more, nor will it permit such impression to be created. It would perhaps be easier at this time to remain silent and let the future solve its own problems. But it would not be honest or fair to the public, to the men, nor to ourselves. Hence, this statement to set the present conditions aright and guard against misunderstanding in the future."

The distinct understanding had with the committee of former employees of the company, together with one of the national board members of the organization, was that while the men were on strike none would be considered for positions on the line. If the men desired to declare the strike off the company announced that it would, when vacancies occurred, consider for employment any men in whom it had confidence. At no time did the company agree to reinstate all but three men.

On Jan. 1 the company discharged five men who were on the committee, representing five-sevenths of said committee, because they broke faith with the company. At no time did the company change its position. These men will not be taken back, but such other men who while on strike were honest with the public and fair to the company will be considered as vacancies occur. The company has at present a full complement of men under contract who will not be discharged without cause. The officers do not, of course, know at this time when there will be any vacancies, but they have notified a committee of the men that when these vacancies occur selections will be made from the old men if they can honestly be considered before new men are employed.

INTERBOROUGH COMPANY PROGRESS

System of 85 Miles of Subway and 117 Miles of Elevated Handles 651,886,671 Passengers for Year

The general remarks contained in the annual report of the Interborough Rapid Transit Company, New York, N. Y., for the year ended June 30, 1914, touch upon traffic carried, the company's financing and new subway construction progress. The company operates all the elevated railway and the subway lines in Manhattan and Bronx boroughs and the present subway extension into Brooklyn. The system comprises 117 miles of elevated railway and 85 miles of subway. In regard to the matters previously mentioned, Theodore P. Shonts, president of the company, says in the report:

"The increase in the net corporate income of your property for the fiscal year ended June 30, 1914, is greater than during the previous year, notwithstanding the general depression in business conditions, which has resulted in almost universal decreases in railroad earnings throughout the country. While a small part of this increase resulted from interference to surface line traffic by snowstorms during the winter, the net result nevertheless establishes in no uncertain degree the stability of the earning power of the rapid transit lines in Greater New York, and furnishes an excellent barometer of the basic value of their securities.

"That this stability of earning power attaches to new rapid transit lines as well, the new mileage creating a corresponding increase in travel commensurate with the additional facilities furnished, is evidenced by the number of passengers carried per annum at the end of each ten-year period since the opening of the elevated lines for operation. In 1874 the Manhattan Elevated Railway carried 796,072 passengers, in 1884 it carried 96,702,620 passengers, in 1894 it carried 196,159,323 passengers, in 1904 it carried 286,634,195 passengers, while in 1914 the elevated and subway lines carried 651,886,671 passengers, an increase of approximately 100,000,000 passengers for each of the ten-year periods during which the facilities were not appreciably increased, and an increase of 365,000,000 passengers during the period of subway operation. The increase in mileage during this last ten-year period, by reason of the construction of the subway, was approximately 70 per cent, while the increase in the number of passengers carried was 127 per cent. Thus the new mileage not only created new traffic equivalent, per mile of road, to the old, but the increase in the number of passengers carried on the combined mileage was greater per mile of road than during any previous ten-year period. This illustrates, as nothing else can, that while the increase in population bears its due relation to the increase in traffic, the number of rides per capita per annum increases in proportion as the facilities for travel multiply.

"Your company's agreement with J. P. Morgan & Company for the purchase of not exceeding $170,000,000 of its 5 per cent bonds, the proceeds to be used for refunding the company's obligations and making its contribution toward the construction and equipment of new subways and elevated extensions, has been modified by a reduction of the company's actual requirements. For the calendar year 1913 the requirements of your company amounted to only $68,658,000 instead of $78,000,000, as mentioned in last year's report. This reduces the total number of bonds to be sold for the purposes above mentioned by $9,342,000, making a reduction in your company's estimated capital obligations to that extent. In addition to the above reduction your company has the option of still further reducing the total amount of bonds to be sold by such amounts as may be found available to the company from other sources for the discharge of its obligations under contract No. 3, and the Manhattan and Interborough certificates.

"Under the terms of contract No. 3 the city, through the

Public Service Commission, has engaged to construct the new subway lines and lease them to your company for operation. In awarding the contracts for this construction, the city's aim has been to place the trunk lines and tunnels under contract in advance of the outlying extensions, so that the entire system may be completed, as nearly as possible, at substantially the same time.

"The Lexington Avenue line from Forty-second Street to 152d Street is entirely under contract and the construction work well advanced. The plans and contract for the short diagonal connection with the present subway at Forty-second Street are about completed and the work will be advertised at an early date. The Seventh Avenue line extending from Forty-second Street to South Ferry is completely under contract, and the work on most of the sections is well under way. The new Brooklyn extension branching from the Seventh Avenue Line at Park Place and extending under the Post-office, William Street and the East River to the Borough Hall Station in Brooklyn, is partially contracted for. The contract for the tunnel under the East River has been awarded and the work is now under way, and the contract for the extension from Clark Street under Fulton Street to the Borough Hall Station of the existing subway is now being advertised. Plans and contracts for the sections under the Post-office and William Street, though somewhat retarded by the protracted negotiations between the city and the federal authorities for the right to pass under the Post-office Building, have now been completed and the contracts are about to be advertised. As soon as these two sections and the diagonal connection at Forty-second Street are awarded, the two principal trunk lines in the Borough of Manhattan and the extension to Brooklyn will be completely contracted for.

"The work on the extension in the Bronx is also well advanced. The Jerome Avenue line extending from 157th Street to Woodlawn Road is under contract, and all of the sections of the White Plains Road line from Bronx Street to 241st Street have been awarded and the work is well under way. The Southern Boulevard line branching from the Lexington Avenue line at 138th Street has also been placed under contract as far as Bancroft Street.

"The contract for the reconstruction of the Belmont Tunnel has been awarded and the work is nearing completion. As soon as completed the tunnel will be available for temporary operation, as contemplated under contract No. 3. The extension from Van Alst Avenue to Queensboro Bridge is also under contract, as well as the lines to Astoria and Corona.

"The extension of the present subway from Atlantic Avenue, Brooklyn, up Flatbush Avenue to the Park Plaza has been placed under contract and the work commenced, but none of the other Brooklyn lines have yet been awarded.

"All of the additional third tracks authorized by the certificate to the Manhattan Railway have been fully legalized by the orders of the Appellate Division in lieu of property owners' consents, and a general contract covering the work has been made.

"Progress has also been made in the preliminary work on the elevated extensions and connections."

WAGE ARBITRATION FINDING

New York State Railways Employees Awarded Slight Increase Dating Back to May 1

In the matter of the arbitration concerning rates of wages between the New York State Railways and the Amalgamated Association of Street and Electric Railway Employees of America, through its divisions at Rochester, Schenectady, Syracuse and Utica, Charles P. Neill, Thomas Spratt and James E. Roach, arbitrators, found as follows on Sept. 4:

"We, the undersigned, Charles P. Neill, Thomas Spratt and James E. Roach, selected under and pursuant to the agreement of arbitration entered into by the above-named parties by written agreement, bearing date of May 21, 1914, beg to report that we have been attended by the respective parties and their representatives and attorneys, have heard the testimony and the arguments by respective counsel, and after due deliberation we find and award that the rate of wages to be paid by the said company to its said employees for a period of one year, being from May 1, 1914, to May 1, 1915, be increased by the payment of an additional 1½ cents per hour over and above the rates respectively paid immediately prior to May 1, 1914, to all of the employees designated in said agreement of arbitration who have heretofore been paid by the hour and that a proportionate increase of wages be paid also to such employees as have been paid by the week or the month for the same period above given.

"We also find and award that where conductors or motormen are used as flagmen on work or utility trains they shall be paid their platform rate. We beg further to add that we have noted with great pleasure that the best and kindliest feelings exist between the officers and employees and we earnestly hope that this condition of mutual good-will may continue for the time to come, as we believe it to be for the best interest of all, including the patrons of this important public utility. Lastly, we hand down this decision to the two parties respectively with the hope that, while it may not be acceptable as a whole to either party, it will be accepted and carried out in good spirit by both parties in the belief that it is our best joint expression of justice in the matter of this arbitration."

The working agreement between the New York State Railways and its employees expired last April. The men asked for an increase in pay from the maximum limit of 26½ cents an hour to 35 cents, basing their claims on the increased cost of living. The company agreed to make a substantial advance provided the new schedule extend over a period of three years. This proposition was refused. Later the company agreed to a slight increase for the current year. Numerous conferences were held without an agreement. As a last resort an arbitration board was appointed, consisting of Thomas Spratt, Ogdensburg, representing the company; James E. Roach, Schenectady, for the employees, and Charles T. Neill, former State Labor Commissioner, as the third member. Hearings were held by the arbitration board in Utica, Syracuse, Rochester and Schenectady since July 1.

LOANS TO SAN FRANCISCO EMPLOYEES

The United Railroads, San Francisco, Cal., has under consideration a plan for making loans to its employees to meet emergencies and contingencies against which its men have been unable to provide. Jesse W. Lilienthal, president of the company, is quoted in this connection in part as follows:

"The details of the plan are about ready to be announced. I am free to give the underlying reasons which have prompted the company to test the plan. I believe it is a wise and proper thing to do, because I do not believe that any corporation gets the best of service from employees who are worried or bothered about financial matters. Any man who is working steadily for a fair rate of remuneration should have some place to go when he needs an accommodation. I recognize that at the present time the salary loan man is about the only source of money for many worthy men. The banks will not loan to these people and many of them have no direction in which to turn. Yet they are honest and in many instances, due to illness and other good reasons, their need for accommodation is great. There is no reason why such people should pay exorbitant rates of interest. Surely character is an asset.

"The United Railroads will have a department to which its employees who need money may turn. If the record of the applicant is good, if the requirement is a legitimate one, there will be no necessity for this employee to go further for money, because it will be supplied. The mode of repayment will be easy and plenty of time will be allowed. In other words, the aim of this department will be to meet a demand that I am sure exists among salaried people everywhere.

"I am just enough of a believer in human nature to think that with this department in operation we will build closer relations with the employees and that any money which may come from this fund will be regarded as a debt of honor by every employee who makes use of this avenue for securing a loan in times of stress. If the plan of the United Railroads proves a success I should like to see other corporations adopt the same course, for I am informed that corporation employees are considered as especially good risks by the salary loan concerns."

CHANGES IN PERSONNEL OF KEY ROUTE

A number of changes have been made in the personnel of the San Francisco-Oakland Terminal Railways, Oakland, Cal., as a result of the inability of George C. Moore and his associates to carry out the plan of financing the company agreed upon when Mr. Moore succeeded to the interest previously held in the company by F. M. Smith. Mr. Moore had arranged to interest capital in Europe in his plans, but the war has prevented him from carrying out the details of the undertaking. Under the new administration the major portion of the old staff of the company under W. R. Alberger has been reinstated, and it is thought that local capital in San Francisco will become interested. It is stated unofficially that the construction work will be continued just as had been planned in so far as this is feasible. A. W. McLimont, general manager of the company, has been succeeded by W. R. Alberger as vice-president and general manager. Robert Morrison, Jr., secretary and assistant treasurer, has been succeeded by Angus Clark, assistant secretary, and F. W. Frost, assistant treasurer. George H. Harris continues with the company as general superintendent. E. M. Boggs continues with the company as chief engineer of docks and wharves. George H. Binckley continues with the company as chief engineer of maintenance of way. F. W. Brown, traffic manager, is succeeded by J. H. Brown. W. E. Hendley, in charge of the efficiency department, is succeeded by U. S. Sliter. L. B. Cramer, electrical engineer, is succeeded by H. P. Bell. Pomeroy Ladue, purchasing agent, has been relieved and purchases will hereafter be handled through the office of the general manager.

REHEARING ASKED IN HOCKING VALLEY CASE

The Hocking Valley Railroad has applied to the Ohio Public Utility Commission for a rehearing of the case in which it was recently ordered to resume the operation of electric service on the Jackson Wellston belt line. Of the fourteen reasons assigned for the rehearing, the most important perhaps is that the Commission does not have jurisdiction to designate the kind of service that a utility shall furnish and that the steam train service substituted for the interurban service is adequate to the needs of the community. The Hocking Valley Railroad operated the electric line for eighteen years in connection with its steam railroad. It also developed power business along the line, but abandoned the service and deprived the users of current.

The commission held that after a railway has gone into a community and supplied it for years it cannot withdraw at will and leave the community without the service. That part of the company's property is suffering a loss just now was not considered sufficient grounds for the abandonment of the service.

PROGRESS ON NEW YORK RAPID TRANSIT CONTRACTS

According to the report of Robert Ridgway, acting chief engineer of the Public Service Commission for the First District of New York, for the month ended Aug. 15, satisfactory progress is being made generally on all rapid transit contracts. Construction work is proceeding actively in the boroughs of Manhattan, Brooklyn, Queens and The Bronx under contracts awarded by the city of New York to twenty-two different contracting firms, who are employing a daily average of 13,000 men. The total contract price of all city contracts awarded to date is $135,910,269, and in addition to this the Interborough Rapid Transit Company and the New York Municipal Railway Corporation have contracts under way to the extent of about $15,000,000 under contractors employing about 2,400 men. While the chief engineer says nothing as to the date of the beginning of operation on any of the lines, it is apparent from his report that the Fourth Avenue subway in Brooklyn and the Steinway tunnel from Manhattan to Long Island City will be the first parts of the dual system to be placed in operation. The outlook is that operation of both these lines will begin shortly after the first of the coming year. At about the same time it is also expected that the two additional tracks in the Centre Street loop subway not now operated will be ready for use, and that the connection of that subway with the Brooklyn and Manhattan bridges will be completed. It is now connected only with the Williamsburg bridge, over which Brooklyn elevated trains have been running into and through the loop subway for the last year.

CONSTRUCTION AND ROUTING PROBLEMS IN CLEVELAND

Application has been made to the City Council of Cleveland, Ohio, by the Cleveland Railway for permission to erect a building at Superior Avenue and East 123d Street to be used as division offices, clubhouse and carhouse. The resolution granting the request has been referred to the street railway committee. The cost of the building is estimated at $128,000.

Director of Public Service Sidlo has requested the company to lay tracks on East Ninth Street from St. Clair Avenue to the lake front in order to take care of the passenger service to the new boat piers which will be completed in the spring. This will probably be commenced within two weeks.

Trouble has arisen over the routing of the West Fourteenth Street cars and Mayor Baker has come forward with a plan that will probably prove satisfactory. Peter Witt, street railway commissioner, opposed a plan that the City Council proposed to adopt.

The charge of 1 cent for transfer was restored on Sept. 1. The change went into effect without active opposition and the charge will continue until the interest fund reaches $700,000. It is estimated that this will require something like a year.

New Pennsylvania Line Opened.—The West Side Electric Street Railway has been placed in regular operation between Charleroi, Bentleyville and Ellsworth, Pa. Hourly service is maintained. The line is 11 miles long.

Tacoma's Proposed Municipal Railway.—The first bids for work in connection with the construction of the proposed municipal railway in Tacoma, Wash., have been opened. They are for pile-driving. While the contract will probably be awarded to the lowest bidder, it will not be signed until the bonds voted for the line have been sold. The bids for the bonds will be opened on Sept. 19. Commissioner of Public Works Woods will receive bids until Sept. 14 for the special work and rails.

Power Station Plans Approved.—The plans and memoranda presented by the Buenos Aires Western Railway, Buenos Aires, Argentina, relative to the erection of an electric power station on a site between the River Plata and the canal of the second section of the South Dock (east side) have been approved by the government. This station is to supply the energy required for electrification of the company's suburban service between Plaza Once and Moreno and also to the tunnel route to the port of Buenos Aires.

Interchange of Transfers Urged in San Francisco.—The exposition committee of improvement clubs has addressed the Board of Supervisors of San Francisco, Cal., urging that an agreement be entered into between the city and the United Railroads for the exchange of transfers to facilitate travel during the exposition period. The matter has been referred to the public utilities committee and Sept. 16 was set as a date for hearing the improvement clubs on the subject. The committee also suggests that the United Railroads, upon some basis to be worked out, be given the right to route its cars over the tracks of the Geary Street Municipal Railway.

Special Issue of "Manufacturer's Record."—The issue of the *Manufacturers' Record* of Baltimore for Sept. 3 was a special edition in two sections. Part I was the regular weekly issue and Part II a special illustrated supplement devoted to the upbuilding work in progress in the city. Since the great fire, ten years ago, some hundreds of millions of dollars have been expended in broad constructive work in the rebuilding of Baltimore. The story of how this has been done and of the work now in prgress appears in full in Part II. Two pages and a half of the issue are devoted to the work of the United Railways & Electric Company in rebuilding and maintaining its system. Six halftone illustrations show some phases of the company's work.

Flood in Manila Interrupts Electric Service.—Electric lighting and street railway service in Manila, P. I., was partially interrupted on Sept. 2 and 3 by a flood resulting from recent typhoons. According to cable advices received from the Manila Electric Railway & Light Company by The J. G. White Management Corporation, New York, N. Y., operating manager of the company, parts of the company's generating plant were under water, the operation of the street railway was interrupted part of one day and considerable difficulty was experienced in maintaining full electric service. On Sept. 3 seventy-five cars were operated. Normal service was resumed on the following day. Aside from slight damage to a few cars and to roadbed of the street railway the company suffered little loss.

Opportunity in Bahamas.—W. F. Doty, United States Consul at Nassau, New Providence, Bahamas, writing to the bureau of domestic commerce, Department of Commerce, says: "An electric street-car system in Nassau and vicinity would probably be profitable, as have others in small tropical communities. Storage-battery cars would make the cost of equipment low. Twenty cars might be sufficient to start with for the city. Later the line might be extended along the western shore to The Caves, Orange Hill, Old Fort, and even to Clifton and Southwest Bay. Several hundred carriages now ply the streets and charge 12 cents per passenger for even two or three blocks. In the heat along unshaded streets one prefers to pay this high fare rather than walk. Improved transportation facilities are therefore needed."

New Haven Dissolution Decree.—The negotiations that have been in progress between the Department of Justice at Washington and the New York, New Haven & Hartford Railroad appear to have reached the point of an "agreed decree" that the company shall dispose of its Boston & Maine stock within a year, or failing that, the courts of Massachusetts shall determine the basis upon which the divorce shall be consummated. In the general plan are included separation of the New Haven from its ownership of the electric railways in Connecticut and Rhode Island, controlled by the Connecticut Company and the Rhode Island Company, respectively, but the fate of its Long Island Sound steamship holdings is left to the discretion of the Interstate Commerce Commission. The new Attorney General has expressed a wish that the civil suit that has been pending shall be settled at the earliest possible moment.

Ohio Valuation Committee in New York.—A committee composed of R. R. Stevens, representing the Ohio independent telephone companies, Robert Lindsey of the Cleveland Electric Illuminating Company representing the gas and electric companies, Allard Smith representing the Cleveland Telephone Company, Frank C. Dunbar, representing the Ohio companies of the American Telephone & Telegraph Company and F. W. Coen, vice-president and general manager of the Lake Shore Electric Railway, representing the electric railways of Ohio, has been in New York for several days on matters connected with the valuation of public utilities ordered by the Ohio Public Utility Commission. By order of the commission every utility in the State must, before Jan. 1, make and file with the commission a certified valuation of all its property. The utilities selected this committee to arrange schedules and to formulate methods of valuation.

Survey Motor Truck Boulevard from City to Port of Los Angeles.—In order to reduce the cost of transporting freight from Los Angeles proper to its water front, it is proposed to build a concrete-paved highway 30 ft. wide specially for the use of automobile trucks. On Aug. 24 the board of supervisors instructed the county road commissioner to survey the proposed route and submit a report estimating the cost of the road. The route proposed is expected to take the auto trucks away from the roads over which the lighter vehicles would naturally travel and runs through the logical industrial and warehouse district. The plan is to begin at Seventh and Alameda Streets and run in a straight line through Vernon and Compton to the harbor front, a total of 18 miles. Interests which have been active in securing a favorable move in this matter are the Automobile Club of Southern California, the Jobbers' Association, the Wilmington Chamber of Commerce and the Harbor Truck Association.

Decision in Seattle Franchise Case.—Judge Jeremiah Neterer in the Federal Court at Seattle, Wash., recently declared valid the franchise of the Seattle, Renton & Southern Railway. This franchise was repealed by the City Council in December, 1910. By the same ruling the city of Seattle acquires the right to connect the tracks of Division "A" of the municipal car line with the tracks of the Seattle, Renton & Southern Railway and operate its cars over the line of the latter on Fourth Avenue. The city also may order the improvement of streets over which the Renton line is routed, and may compel the company to conform to these improvements in the construction of its tracks. If the City Council still desires to have municipal cars run into the downtown districts from Division "A" and the Lake Burien line, the Seattle, Renton & Southern Railway, under its franchise, must grant common user rights to the city. Under the decision the city will have access for Division "A" cars to the Union Depot and to the station of the trans-continental lines which operate into Seattle.

Public Utility Legislation in Alabama.—Although the next session of the Alabama Legislature will not be held until January the political platform builders are predicting the trend that legislation will probably take. The Birmingham *Age-Herald* recently discussed the prospects for public utility legislation in part as follows: "Probably one of the most important questions which will come before the next Legislature is the establishment of a public utility commission. Such a commission would have powers similar to those of the present Railroad Commission, though much wider in scope. For instead of railroads and street railways, the utility commission would have supervision over all public service corporations, such as water power and electric companies, steamship lines, telegraph and telephone companies, ferries and all other public utility concerns. That the next Legislature will endeavor to establish a public utility commission there is little doubt, and it is also probable that the state lawmakers will attempt to make the members of the commission appointive rather than elective."

Official Opening of New Utah Line.—The official opening of the Salt Lake & Utah Railroad between Salt Lake City and Provo, Utah, took place the last week of August, although electric trains were placed in operation between the two cities on July 24, as noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, page 271. The celebration was under the direction of the Provo Commercial Club. Governor William Spry, the mayors of all the cities along the line of the new road and many other prominent citizens were among those who participated. The celebration ended with a banquet, where covers were laid for 200 guests. W. C. Orem, president of the company, and his associates were complimented and congratulated on the completion of the road. The line now in operation is 48.5 miles long. It will be extended southward from Provo to Payson, Utah, 20 miles. Connections are made at Salt Lake City with the Salt Lake & Ogden Railroad, thus giving electric service from Provo to Brigham City, Utah, a distance of almost 100 miles. A joint terminal building will be erected at Salt Lake City.

Disbursements for Rapid Transit Work in New York.—The Public Service Commission for the First District of New York has furnished the Department of Taxes with a statement of the disbursements made by the city of New York for rapid transit purposes from the beginning of the existing subway work to June 30, 1914. The statement also shows the disbursements for the first six months of 1914, by which it appears that the city of New York for those six months paid out on an average more than $1,650,000 a month, or a total for the six months of $9,703,443. In addition during the same six months the Interborough Rapid Transit Company paid out of its contribution $560,289 and the New York Municipal Railway Corporation out of its contribution $393,005 on account of city-owned line construction. Excluding purchases of real estate the disbursements of the city for regular and extra work in rapid transit construction from the beginning to June 30, 1914, aggregate $100,338,171, of which more than $48,000,000 is chargeable to the existing subway. These figures represent actual disbursements. The total amount of contracts awarded by the city to Aug. 15, 1914, aggregated $135,910,269 on the new lines alone.

Financial and Corporate

RECENT FINANCIAL TENDENCY

Stock Exchange, Customs, Foreign Exchange and Railroad Problems Reviewed Briefly

Suggestions continue to be advanced looking toward the resumption of business on the New York Stock Exchange. Such ideas as have been put forward, however, are by no means unanimous. It is not intended here to review any considerable number of such plans. Two examples will suffice to illustrate the divergence of the views which have been expressed lately. The *Financial and Commercial Chronicle* recommends a $500,000,000 banking syndicate to take over at private sale the foreign holdings of American securities that remain to be liquidated. Under the plan suggested this syndicate would not engage to sell on the Stock Exchange at all, but would place the securities taken over with moneyed people with an appreciation of the value of the securities offered for sale.

On the other hand M. E. de Aguero, president of the Consolidated Exchange, thinks that the solution of the problem of resuming trading might be found in Congress authorizing the Secretary of the Treasury to issue treasury notes not to exceed $5,000,000,000 to acquire dividend and interest paying stock and bonds held abroad, the return on such securities to be converted into a sinking fund to retire a corelative amount of the treasury notes. Following the retirement of all the notes at the end of twenty years the income could be applied to the general uses of the government.

Another question of pressing concern is the one of overcoming the problem of the dwindling customs returns and of keeping the treasury unimpaired. The customs revenues for August fell off $10,629,538 as compared with August, 1913. President Wilson has estimated that with a continuation of this decrease in the same proportion for the current fiscal year there would be a loss in customs revenues of from $60,000,000 to $100,000,000. He is opposed to borrowing and has suggested taxation as the alternative.

Addressing Congress the President recommended that "such source of revenue be chosen as will begin to yield at once and yield with a certain and constant flow." In this connection taxes were first suggested on magazines, gasolene, beer, patent medicines, soft drinks and railroad and amusement tickets. On Sept. 8 the Democrats of the House ways and means committee completed their deliberations over the emergency tax measure. It was said at the time that the majority favored the raising of the present income tax and its extension to include incomes of $2,000 of unmarried persons and $3,000 of married persons. On Sept. 10 it was announced, however, that the new bill would be introduced on Sept. 11 and that it would provide for a tax of 3 per cent on railroad freight, from which it is estimated $65,000,000 will be realized annually, an additional tax of 50 cents a barrel on beer, which will bring in about $33,000,000, and a tax of 20 cents a gallon on domestic wines, the probable yield of which will be $9,000,000.

The committee appointed on Sept. 4 by the conference of clearing house delegates to solve the foreign exchange problem completed its report on Sept. 5 and submitted it to the comptroller of the currency. This committee, of which James B. Forgan, Chicago, is president, recommended that the banks be requested to contribute to a gold fund of $150,000,000, of which $25,000,000 would be immediately paid into the depository of the Bank of England in Canada, the remainder of the amount to be payable subject to call. J. P. Morgan and Jacob H. Schiff conferred on Sept. 10 with Secretary of the Treasury McAdoo and the Federal Reserve Board in regard to this plan. The official announcement which Mr. McAdoo made following the conference was concluded with the statement that "the board has not yet taken any action in the matter, but has the whole situation under advisement." It is said, however, that members of the Reserve Board expressed approval of the Forgan plan in principle, but found it difficult to arrange the details for carrying it out. The New York bankers told the members of the board that a syndicate had been formed with the banking houses of J. P. Morgan & Company and Kuhn, Loeb & Company to take charge of the maturing obligations of New York City within the next two months, amounting to $82,000,000. It was explained that the New York syndicate had done, or was preparing to do, precisely what the Forgan committee recommends should be done by the bankers generally throughout the country.

In connection with the matter of restoring normal market conditions for international exchange David Lloyd-George, Chancellor of the Exchequer of England, announced on Sept. 4 that the Bank of England would provide acceptors with the funds necessary to pay at maturity all bills contracted before the moratorium was declared, acceptors to be under obligation to collect from their clients as soon as possible the funds due them and apply such funds to the advances made by the bank, for which interest will be charged at 2 per cent above the ruling bank rate.

On Sept. 9 the President met a delegation of railroad men at Washington to consider the financial situation which confronts the railroads. This committee submitted two requests to the President, namely, that attention be called to the need for the support of railroad credits and that recognition be urged of the need for increased revenues on the part of "the appropriate governmental agencies," supposedly the Interstate Commerce Commission. With the President's approval the committee issued a statement dealing with the problem before the railroads. This statement characterized the situation as "an emergency of a magnitude without parallel in history."

Sterling exchange was very strong on Sept. 9, cable transfers being quoted as high as $5, and demand bills at $4.99. The quotations on Sept. 8 were as low as $4.98 for cables and $4.97 for demand. It was reported that the rise was due almost wholly to heavy buying of exchange by the banking syndicate which is floating the 6 per cent notes of the city of New York. The statement was made on Wednesday that more than 140 institutions have signified their intention to take the new notes, which were to be issued on Sept. 11. The first of the city's foreign obligations will be paid on Sept. 14 out of funds furnished by the purchasers of the city bonds.

The first regular meeting of the Stock Exchange governors since June 24 last was held on Sept. 9, but only routine business was transacted. The question of opening the exchange was not discussed, according to one of the members.

PACIFIC GAS & ELECTRIC COMPANY FINANCING

According to the complete text of the order of the California Railroad Commission, the Pacific Gas & Electric Company was recently authorized to issue $5,000,000 face value of general refunding mortgage 5 per cent gold bonds, series A, maturing in January, 1942; $12,500,000 par value of first preferred stock; as much additional first preferred stock as may be necessary to exchange for original preferred stock on and after July 1, 1916, and common capital stock of the par value of $1,159,800. The company is restricted from issuing the above-named bonds until it has secured from the commission a supplementary order specifying the minimum selling price. It must sell the first preferred stock so as to net in cash not less than 82½ per cent of the par value, and also dispose of the common stock at not less than par.

The company is to use the proceeds from the sale of the $5,000,000 of bonds and the $12,500,000 of first preferred stock to discharge and refund its 6 per cent and its 5 per cent gold notes, proceeds not to exceed $7,000,000; to discharge and refund obligations incurred and reimburse its treasury for the acquisition of property and the making of improvements, proceeds not to exceed $4,586,661, and to cover such other capital expenditures as may be supported by supplementary orders from the commission. The proceeds from the sale of the common stock are to be used for the reimbursement of moneys expended for the retirement of bonds through sinking funds from Jan. 1, 1914, to April 30, 1914, not to exceed $40,760; to provide cash for meeting sinking fund payments now due and unpaid, not to exceed $394,376, and to provide cash for retiring bonds through sinking funds from April 30 to Dec. 31, 1914, not to exceed $724,687. Previous references to the new financing of the Pacific Gas & Electric Company were made in the ELECTRIC RAILWAY JOURNAL of July 11, July 25, Aug. 15 and Aug. 29.

ANNUAL REPORT

Interborough Rapid Transit Company

The comparative statement of income, profit and loss of the Interborough Rapid Transit Company, New York, N. Y., for the years ended June 30, 1913 and 1914, follows:

	1914			1913		
	Manhattan Railway Division	Subway Division	Total	Manhattan Railway Division	Subway Division	Total
Revenue from transportation	$15,594,075	$17,003,496	$32,597,571	$15,365,164	$16,358,675	$31,723,839
Other street railway operating revenue	360,762	557,061	917,824	324,751	449,280	774,031
Gross operating revenue	$15,954,837	$17,560,557	$33,515,395	$15,689,915	$16,807,955	$32,497,870
Operating expenses:						
Maintenance of way and structures	$906,064	$800,633	$1,706,697	$906,377	$791,581	$1,697,958
Maintenance of equipment	1,090,001	1,234,309	2,324,311	1,022,229	1,781,057	2,803,287
Traffic	102	36	138	277	175	453
Transportation expenses	4,142,751	3,384,063	7,526,815	4,045,763	3,364,179	7,409,941
General expenses	591,317	752,776	1,344,092	641,692	707,413	1,349,104
Total operating expenses	$6,730,235	$6,171,817	$12,902,053	$6,616,338	$6,644,405	$13,260,743
Net operating revenue	$9,224,602	$11,388,740	$20,613,342	$9,073,577	$10,163,550	$19,237,127
Taxes	1,695,760	386,188	2,081,948	1,727,475	389,405	2,116,880
Income from operation	$7,528,842	$11,002,552	$18,531,394	$7,346,102	$9,774,145	$17,120,247
Non-operating income	59,713	553,139	612,852	47,444	440,046	487,490
Gross income	$7,588,555	$11,555,691	$19,144,246	$7,393,546	$10,214,191	$17,607,737
Income deductions	5,882,656	$5,237,010	$11,119,666	$5,865,156	$5,205,513	$11,070,669
Net corporate income	$1,705,899	$6,318,681	$8,024,580	$1,528,390	$5,008,678	$6,537,068
Dividends on Interborough Rapid Transit Company stock (10 per cent—5 per cent extra for 1914, 2 per cent extra for 1913)	....	5,250,000	5,250,000	....	4,200,000	4,200,000
Surplus	$1,705,899	$1,068,681	$2,774,580	$1,528,390	$808,678	$2,337,068
Per cent expenses to earnings:						
Excluding taxes	42.18	35.14	38.49	42.17	39.53	40.80
Including taxes	52.81	37.34	44.71	53.18	41.85	47.32
Passengers carried	311,473,568	340,413,103	651,886,671	306,845,006	327,471,510	634,316,516
Daily average passengers carried	853,352	932,639	1,785,991	840,671	897,182	1,737,853

The gross operating revenue for the year ended June 30, 1914, was $33,515,395, an increase of $1,017,525, or 3.3 per cent. The net corporate income was $8,024,580, equivalent to 22.92 per cent on the capital stock of the company, as compared to 18.68 per cent for the preceding year, 16.07 per cent for 1912 and 14.68 per cent for 1911. The operating expenses were $12,902,053, a decrease of $358,690, or 2.7 per cent. The amount charged to operating expenses and credited to the depreciation reserve was $655,993 below the charge for the previous year, but the expenditures for maintenance showed an increase of $185,757, resulting in a net decrease in charges for both depreciation and maintenance of $470,236. The cost of operation, exclusive of depreciation and maintenance, increased $111,546. The "tax refunds and other credits" for 1914 showed a decrease of $2,303,483, because during the year ended June 30, 1913, there was carried to profit and loss $2,057,033 of interest upon advances made to the trustees of the New York & Long Island Railroad to provide means for the construction of the Belmont tunnel. The total surplus on June 30, 1914, was $15,214,403, as compared to $13,072,956 the year previous.

The gross operating revenue gained on the subway division was $752,602, or 4.48 per cent, and on the Manhattan Railway division $264,923, or 1.69 per cent. The operating expenses of the subway division decreased $472,588, or 7.11 per cent, while the Manhattan Railway division expenses increased $113,898, or 1.72 per cent. The net operating revenue of the entire system was $20,613,342, an increase of $1,376,215, or 7.15 per cent over 1913, resulting from a gain on the subway division of $1,225,190, or 12.05 per cent, and a gain on the Manhattan Railway division of $151,025, or 1.66 per cent.

The total amount of taxes was $2,081,948, as compared to $2,116.880 in 1914, a decrease of $34,932, or 1.65 per cent, the subway division decreasing $3,217, or 0.82 per cent, and the Manhattan Railway division $31,715, or 1.83 per cent. Income from operations increased $1,411,147, or 8.24 per cent, the subway division increasing $1,228,407, or 12.57 per cent, and the Manhattan Railway division $182,740, or 2.49 per cent. The non-operating income of the company increased $125,362, or 25.71 per cent, principally owing to the increase in interest on bank balances and loans. The subway division showed a gain of $113,093, or 25.7 per cent, while the Manhattan Railway division increased $12,269, or 25.87 per cent. The gross income increased $1,536,509, or 8.72 per cent, the subway division gaining $1,341,499, or 13.13 per cent, and the Manhattan Railway division $195,099, or 2.64 per cent. The total income deductions increased $48,997, or 0.44 per cent. The net corporate income increased $1,487,512, or 22.75 per cent, the result of a gain on the subway division of $1,310,003, or 26.15 per cent, and on the Manhattan Railway division of $177,509, or 11.61 per cent.

The surplus over dividends of 15 per cent (including the extra dividend of 5 per cent) on the capital stock was $2,774,580. On a basis of 10 per cent dividends for each year the surplus for 1914 would be $4,524,580, as compared to $3,037,068 for 1913, giving $1,487,512 as the gain in surplus over the concluding year. The operating ratio for 1914 was 38.49 per cent, as compared to 40.8 per cent for the preceding year, a decrease of 2.31 per cent, the result of a decrease on the subway division of 4.39 per cent and an increase on the Manhattan Railway division of 0.01 per cent. The total number of passengers carried was 651,886,671, as compared to 634,316,516 for 1913, an increase of 17,570,153, or 2.77 per cent. The subway division traffic increased 12,941,593, or 3.95 per cent, and the Manhattan Railway division traffic increased 4,628,562, or 1.41 per cent.

There was expended for maintenance throughout the year $3,700,513. The report gives in detail the various items included among maintenance expenditures, among which are the following: steel rails renewed on 17 miles of single track, 28,500 ties renewed and station platform extended at nine stations on the Manhattan Railway division; steel rails renewed on 21 miles of single track, 16,618 ties renewed, 297 cars equipped with porcelain enameled sanitary hand-holds and 283 cars furnished with white enameled ceiling on the subway division. Additions and betterments for the year ended June 30 chargeable to capital account amounted to $233,963 on the Manhattan Railway division, and $115,430 on the subway division, while charges for improvements under the new subway system totaled $8,426,882.

The report states that the substitution of heat-treated for non heat-treated axles is being continued and also that subway cars are being made more sanitary and better lighted by the substitution of white enameled ceilings and white decorations. Experiments are being continued with a view to providing better facilities for identifying private subway entrances through office buildings, etc. Along the lines of the new elevated construction the company has secured easements for approximately one third of the frontage affected.

The amount expended for claims, suits and damages in 1914 was $296,415, a decrease of $65,927. Expenses were

$160,148, an increase of $6,932, or a net decrease of $58,995, or 11 per cent. The company voluntarily settled 3094 claims for $152,839 before any suit was brought and compromised 318 suits before trial for $118,734. The total judgments paid during the year aggregated $24,841. The plaintiffs lost 71 per cent of all cases, compared to 65 per cent for the preceding year. The aggregate verdicts during the year amounted to $28,289, or $37,871 less than in 1913. The disbursements for claims, disputes and damages amounted to 0.88 per cent of the gross operating revenue, and expenses were 0.48 per cent, or a total of 1.36 per cent of the gross, compared to 1.58 per cent during 1913.

Birmingham, Ensley & Bessemer Railroad, Birmingham, Ala.—The Birmingham, Ensley & Bessemer Railroad has defaulted interest due Sept. 1 on its $2,650,000 of first mortgage 5 per cent bonds dated 1911 and due March 1, 1941. The Equitable Trust Company, New York, is trustee. This company operates under a ninety-nine-year franchise in Birmingham and under a perpetual franchise in Bessemer. It has 36 miles of track in operation, with a total of fifty-two cars. Operation was begun in September, 1912.

Central California Traction Company, San Francisco, Cal.—G. A. Starkweather has been elected a director of the Central California Traction Company, to succeed Walter Arnstein, resigned.

Chicago (Ill.) Railways.—It is reported that no further payments will be made this year on the series 2 participation certificates of the Chicago Railways, all the cash funds of the company being required for corporate purposes. An initial distribution of $2 per share was made on this class last February.

Cleveland (Ohio) Railway.—Application has been made to the Ohio Public Service Commission by the Cleveland Railway for permission to issue $1,068,500 of additional capital stock. The proceeds are to be used to reimburse the company for expenditures made for extensions and betterments and also to pay for further extensions that are to be made.

Gary & Interurban Railroad, Gary, Ind.—Interest due Sept. 1 on the $350,000 of three-year 6 per cent notes of the Gary & Interurban Railway is in default and the Baltimore Trust Company, as trustee of the mortgage under which the notes were issued, is taking steps to protect the holders' interest. Under the Indiana law stockholders can, it is said, be assessed without foreclosure, and failure to pay the assessment within the prescribed time subjects them to forfeiture of their stock. Acting under this law, the company has called upon the stockholders for the payment of an assessment of 10 per cent within sixty days. Since there is $4,750,000 of stock on the Gary & Interurban Railroad outstanding, the assessment equals $475,000, which would enable the company to pay off its floating debt and leave a balance of about $125,000. The notes are secured by $500,000 of first mortgage 5 per cent bonds and $500,000 of stock of the East Chicago Railway, a link in the Gary & Interurban system.

Idaho Railway, Light & Power Company, Boise, Idaho.—According to Receiver W. J. Ferris, a recent decision of Judge Dietrich of the United States Circuit Court removes all doubt regarding the stability of the Idaho-Oregon Light & Power Company and opens the way for the bidding in of the property by the bondholders at the forthcoming sale on Sept. 30. The judge held that $718,000 of first and refunding mortgage bonds claimed to be owned by the Idaho Railway, Light & Power Company were obtained without consideration.

Jamestown, Westfield & Northwestern Railroad, Jamestown, N. Y.—The Public Service Commission for the Second District of New York recently granted an application to change the motive power of the Jamestown, Westfield & Northwestern Railroad from steam to electricity and to issue $100,000 of capital stock, which is to be given to S. B. Broadhead and A. W. Broadhead in part payment for the properties purchased from the receiver of the Jamestown, Chautauqua & Lake Erie Railway. The order of the commission does not consider the question of paying the balance to the vendors, said to be $357,500, which it is proposed to meet by an issue of mortgage bonds. The commission has approved the lease to the Erie Railroad of certain portions of the line and of the freight terminal east of Fairmont Avenue in Jamestown and the Falconer branch line. The Jamestown, Westfield & Northwestern Railroad was formerly the Jamestown, Chautauqua & Lake Erie Railway, the sale of which to the Broadhead interests was noted in the ELECTRIC RAILWAY JOURNAL of Sept. 1 and Oct. 25, 1913. These interests also own the Jamestown Street Railway and the Chautauqua Traction Company.

Lethbridge Municipal Railway, Lethbridge, Alta., Can.—According to the city auditor's report, the car earnings of the Lethbridge Municipal Railway for 1913 amounted to $59,045. The income from advertisements was $1,564, giving total receipts of $60,609. Direct operating expenses for maintenance and repairs, labor and sundries totaled $59,873. To this was added $4,884 for general and miscellaneous expenses, giving a total of $64,757 for working expenses. The net loss in earnings for the year, therefore, was $4,148. When this was increased by the addition of debenture interest, $14,813, other interest, $4,982, and sinking fund payments, $6,888, the total deficit for the year was $30,831. This compared with the deficit for 1912 of $5,176, shows an increase of more than 500 per cent.

Los Angeles (Cal.) Railway.—A final hearing was recently held by the California Railroad Commission regarding the application of the Los Angeles Railway to issue $23,544,000 of bonds. The city of Los Angeles is resisting the application of the Los Angeles Railway Corporation and its subsidiary, the City Railway, to transfer their properties to the newly incorporated Los Angeles Railway, and the plan of the latter company to issue the above mentioned amount of bonds in exchange for the bonds of the Los Angeles Railway Corporation and the City Railway. The main question at issue between the city and the railways has been that of the value of the two operating lines and the bonds to be issued in accordance therewith. The companies assert that the present value of the property is $24,288,400 and the reproductive value $26,030,865; while the city estimates $14,782,112 as the present value and $19,762,389 as the reproductive value. The question of value has finally been submitted to State Railroad Commissioner Edgerton for decision. The plan of financing for the new company was described in the ELECTRIC RAILWAY JOURNAL of Dec. 13, 1913, and the different valuation figures were noted in the issues of Jan. 31 and March 28, 1914.

Los Angeles & San Diego Beach Railway, San Diego, Cal.—The California Railroad Commission has issued a supplemental order authorizing the Los Angeles & San Diego Beach Railway to issue two promissory notes, totaling $34,000, to be used in renewing similar notes outstanding.

New York (N. Y.) Railways.—Theodore P. Shonts, president New York Railways, has issued the following statement: "The New York Railways has prepared a summarized statement showing the net income payable as interest on the adjustment mortgage bonds for the six months ended June 30, 1914, amounting to 1.24 per cent. The mortgage provides that such a statement must be signed by three-fourths of the directors to be elected by the bondholders. The unavoidable absence in Europe of one of the directors representing the bondholders, and the refusal of another to sign the approval, made it necessary to agree with the trustee of the mortgage upon the selection of a board of experts to ascertain the income. The directors have authorized the necessary procedure and there probably will be no delay in the interest payment due Oct. 1."

Ocean Shore Railroad, San Francisco, Cal.—The California Railroad Commission has issued an order dismissing the application of the Ocean Shore Railroad for permission to issue $200,000 face value of bonds. The application was dismissed at the request of the company.

Sedalia Light & Traction Company, Sedalia, Mo.—The Sedalia Light & Traction Company secured permission on Aug. 28 to sell $91,600 of its bonds at 75.

Utah Light & Railway Company, Salt Lake City, Utah.—The Utah Power & Light Company has applied to the Salt Lake City Commission for permission to purchase the Utah Light & Railway Company, which owns and operates an electric railway and electric light and power system in Salt Lake City and adjoining towns, as well as a gas, electric and power system in Ogden. This is merely a formal step. As noted in the ELECTRIC RAILWAY JOURNAL of Sept. 5, the Salt Lake Light & Traction Company has been incorporated by officials of the Utah Power & Light Company to take over the Utah Light & Railway Company, and if the plan is successful this new company will own the 98 per cent interest in the common and preferred stocks of the Utah Light & Railway Company, which is now owned by the Union Pacific interests through the Oregon Short Line. The stockholders of the Utah Light & Railway Company are to vote on Sept. 18 on the question of approving the sale of their properties. The Utah Power & Light Company, the issued stock of which is owned by the Utah Securities Company, is to own all the outstanding stock of the Salt Lake Light & Traction Company and will finance the acquisition of the Utah Light & Railway Company by means of its own treasury and securities now on hand. The acquisition will give full control of the electric business in both Salt Lake City and Ogden to the Utah Power & Light Company.

Warren, Brookfield & Spencer Street Railway, Brookfield, Mass.—A report has been filed with the Supreme Court of Massachusetts by Frank Paul, master, setting forth $75,000 as a fair price for the properties of the Warren, Brookfield & Spencer Street Railway and recommending that Thomas T. Robinson, receiver, be permitted to sell at this price. The original price set by the owners was $150,000, and three attempts have been made to sell the road at auction. The master recommends that the next sale be held on Jan. 14.

Winnipeg (Man.) Electric Railway.—It is stated by officials of the Winnipeg Electric Railway that the revenues of the company will be materially affected by the industrial depression in Canada resulting from the European war. At present the effect is most noticeable in the hours when the heavy traffic of men to and from work usually keeps the cars busy. This patronage is steadily becoming smaller. All undertakings which the company has under way will be completed, but no new work will be considered until financial developments of the future can be clearly seen.

DIVIDENDS DECLARED

Arkansas Valley Railway, Light & Power Company, Pueblo, Col., quarterly, 1¾ per cent.

Brockton & Plymouth Street Railway, Plymouth, Mass., 3 per cent, preferred.

Duluth-Superior Traction Company, Duluth, Minn., quarterly, 1 per cent, common; quarterly, 1 per cent, preferred.

El Paso Electric Company, El Paso, Tex., quarterly, 2¼ per cent, common.

Federal Light & Traction Company, New York, N. Y., quarterly, 1½ per cent, preferred.

Honolulu Rapid Transit & Land Company, Honolulu, Hawaii, quarterly, 2 per cent.

Twin City Rapid Transit Company, Minneapolis, Minn., quarterly, 1½ per cent, common; quarterly, 1¾ per cent, preferred.

United Traction & Electric Company, Providence, R. I., quarterly, 1¼ per cent.

Traffic and Transportation

SUBURBAN FARE INCREASE

Railroad Commission of Oregon Grants Application of United Railways, Portland, for Suburban Fare Increase

Holding with the complaint of the company that its revenues are not just and adequate, the State Railroad Commission of Oregon has issued an order increasing the rates of the United Railways on its Portland-Linnton line. The new rates from Portland, which became effective on Sept. 1, compare with the old ones as follows:

Station	Miles	Present rate	New rate
Stockdale	4.0	$0.05	$0.05
Cliff Inn	4.5	.05	.10
Linnton, Willbridge, Webster, West Oregon Lumber Company and intermediate stations	8.7	.05	.10
Harborton	10.1	.10	.15
Miller	10.5	.15	.20
Armona	10.8	.15	.20
Burlington	13.1	.20	.20
Falkenburg	14.8	.25	.25
Tunnel Spur	15.3	...	.30
Rockton	16.7	.30	.30
Valle Vista	17.6	.35	.35
Bowers	18.4	...	.40
Helvetia	18.9	.40	.40
Groveland	19.7	.45	.45
Connell	20.5	.45	.45
Lincoln	21.6	.50	.50
North Plains	23.3	.55	.55
Davis	24.6	...	.60
Dersham	25.1	.60	.60
Christie	26.8	.65	.65
Wilkesboro	27.8	.70	.70

The increases are largely between Portland and near-by stations. Many rates between intermediate stations and virtually all rates on the west end of the road remain unchanged or are slightly decreased by a readjustment proposed by the company. The company has for some time issued Saturday to Monday round-trip excursion tickets between Portland and stations west of Harborton, and special Sunday round-trip tickets from Portland to stations Miller to Burlington, inclusive. It also has a thirty-ride family commutation ticket between Portland and stations from Burlington to Wilkesboro, inclusive, limited to ninety days from the date of sale. It is proposed to extend the Saturday to Monday round-trip rates to include all stations, and to make certain increases in the special Sunday round-trip tickets to make them approximately one and one-third times the one-way local fare. It proposes to furnish in lieu of the thirty-ride family ticket a fifty-ride individual commutation ticket, limited to thirty days from date of sale between Portland and stations east of and including Tunnel Spur. The basis suggested is about 1 cent a mile. It will furnish a twenty-five-ride commutation ticket, limited to ninety days from date of sale, between Portland and all stations, the basis of the charge being 1½ cents a mile.

Regarding the answer of the city of Portland to the complaint, in which it sets forth that the franchise of the company provides it shall charge 5 cents for each passenger over its line in that city, the commission says:

"The question as to whether the rate of fare named in the franchise granted by the County Court of Multnomah County to the company was a contractural condition, and as to whether the company can or should be allowed to keep the consideration granted it, that is, the right-of-way over the Portland and St. Helens road, and at the same time repudiate the rate of fare named in the franchise from the County Court, are judicial and not administrative in nature, and are not within the jurisdiction of the commission to determine."

Permission to increase rates within Portland was not asked in the complaint.

The commission found that the original cost of the operating properties of the main system, which does not include the Mount Calvary line, rates for which were not considered, was approximately $2,756,367. Of this $1,893,448 represents the original cost of the road and general expenses of the line between Linnton and Wilkesboro, and $731,265 the original cost of the road and general expenses east of Linnton.

To reproduce the operating main line properties of the company other than the Mount Calvary line, the commission estimates it would cost $2,175,460. The total operating revenue of the company for the fiscal year ended June 30, 1913, was $123,337. There were transported during the year 704,091 passengers between Portland, Linnton and intermediate stations, the average cost to the company of each passenger being 9 2-3 cents. There were transported during the year on the main line 727,283 passengers at an average cost a passenger of 8.81 cents, with revenue derived of 8.55 a passenger, or 2.6 mills less than cost.

RAILROAD PASSENGER FARE INCREASES IN NEW YORK

The Public Service Commission of the Second District of New York has included in its bulletin of tariff changes for the week ended Sept. 3 the almost universal increase of passenger mileage rates in the State, to be effective on Oct. 1, by the railroads taking advantage of the recommendations of the Interstate Commerce Commission in the Eastern freight rate cases. Generally speaking, these increases represent a change from 2 cents a mile to 2 @ 2¼ cents a mile on all mileage books. The New York Central does not increase its 2-cent rate, but subjects its mileage books to numerous restrictions not heretofore imposed, such as the discontinuance of its 500-mile book, and the restriction of the use of the 1000-mile book to between points on its own lines and those of the West Shore on a journey wholly within the State of New York.

In many instances limits of tickets are changed from "Good until used" to "One year from date of sale." With the exception of the Delaware & Hudson Company all mileages sold prior to Oct. 1 will be honored according to the contract under which sold. The Delaware & Hudson Company will redeem all mileage unused on Oct. 1 at 2 cents per mile. Many minor changes have also been made on certain special rates heretofore in vogue. Among the more important of these is the discontnuance of the 100-person round trip ticket rate much used by theatrical and other large parties traveling together. This type of ticket made available for a party of 100 or more traveling together a round-trip rate of 3 cents a mile, or 1½ cents a mile per mile actually traveled. The Delaware & Hudson Company has almost wholly done away with the practice of selling individual round-trip tickets at rates less than the rate for two single-way tickets.

In the case of the trunk line interchangeable 1000-mile refund tickets, all roads selling these forms have changed the regulations governing the redemption value of the cover so as to raise the rate for travel from 2 cents to 2¼ cents a mile. While this form of ticket has never been good over the Lake Shore, the New York Central, or the West Shore, such tickets sold after Oct. 1 will be honored by these roads.

Near-Side Stop in Belleville.—The East St. Louis & Suburban Railway, East St. Louis, Ill., on Sept. 1 inaugurated a near-side stop policy for its cars in Belleville, Ill.

Freight Right Allowed in Massachusetts.—The Public Service Commission of Massachusetts has authorized the Bay State Street Railway to act as a common carrier of baggage and freight in Dighton.

Minister Preaches "Safety First."—The work of the Lincoln (Neb.) Traction Company in placing warning signs on its cars was praised by Rev. H. H. Heberly, a local pastor in that city, who delivered a sermon on "safety first."

Berkshire Street Railway Agreement.—An agreement as to new working conditions for employees has been signed by officials of the Berkshire Street Railway, Pittsfield, Mass., and of the men. This contract will expire on June 1, 1915.

Newsboys a Menace.—The Public Service Commission of Maryland has asked its general counsel for an opinion as to whether it has authority to exclude newsboys from the street cars while selling papers. This action is the result of a number of accidents which have occurred recently.

New Traffic Regulation in Jackson.—New regulations to govern street traffic have been adopted by the City Commissioners of Jackson, Miss. A feature of the new regulations is the provision that automobilists who persist in passing street cars which have stopped to take on or discharge passengers shall be liable to arrest.

Change in Fares on New York State Railways.—The New York State Railways, Rochester, N. Y., has amended its passenger tariff eliminating collection of any excess fare when paid on cars and reducing the fares for the fifty-four-trip commutation and forty-six-trip school commutation tickets for all distances 5 miles and over.

Safety Slogans for Employees.—The Utah Light & Railway Company, Salt Lake City, Utah, has issued an eight-page booklet "Safety Slogans for Employees." The book is 4 in. wide by 6 in. high and is bound in a heavy paper cover. The advice contained in the publication is addressed under separate headings to carmen, linemen, station employees, shopmen and track employees.

Electric Railway Hospital Car.—A car of the Southern Michigan Railway was chartered recently to convey a prominent resident of South Bend, Ind., to that city from St. Joseph, Mich., where he was taken sick suddenly. The car was converted into a temporary hospital ward, a doctor and nurse being in attendance upon the man as well as the members of the family who were with him when he was stricken.

Co-operative Store in Kansas City.—Employees of the Metropolitan Street Railway, Kansas City, Mo., at the Fifteenth and Kensington Street carhouse, have organized a co-operative store. They have rented a building and are selling stock to trainmen. There are 150 trainmen living near the carhouse. Employees working at other stations of the company are also talking of forming similar organizations for the sale of family supplies.

Discouraging Conversation With Motormen.—The motormen in the employ of the Dubuque (Ia.) Electric Company have been furnished with a card which it is intended they shall hand to passengers who attempt to engage them in conversation while they are on duty. The card reads: "The safety of passengers and the operating rules of the company forbid that I should carry on conversation with a passenger while engaged in the performance of my duty. Please help me to observe this rule in both letter and spirit."

Louisville Safety Zones Indorsed.—The action of the Louisville (Ky.) Railway and the Board of Public Safety in establishing safety zones at busy Louisville corners has been indorsed by the directors of the Louisville Commercial Club, which says: "This device will undoubtedly meet with popular approval, both with pedestrian and motorist, and will materially aid careless drivers in a more strict adherence to the new automobile law which prohibits motor vehicles from passing a car stopped at a street corner."

Near-Side Stops in Lexington.—In Lexington, Ky., the Kentucky Traction & Terminal Company has begun an experiment by which only the front doors of the street cars will be used, the ultimate intention being to close the rear entrances. At the same time it was ordered that cars should stop on the "near side" at all street intersections and that smoking would be permitted only on the inclosed rear platform. The conductor is posted at the front end, just back of the motorman, occupying the position formerly assigned to two seats.

Transfers in Los Angeles.—The public utilities committee of the City Council of Los Angeles, Cal., has recommended that the petition of the Edendale Improvement Association relative to the city taking steps to secure a system of universal transfers be referred to the Public Utilities Commission, in connection with other petitions and communications on this subject. The papers will be placed before the commission and it is expected that a statement will be sent to the Council by President Wright explaining the commission's stand on this subject.

New Experimental Trailer in Kansas City.—The Kansas City (Mo.) Railways has remodeled one of its trailers on a new plan, with entrance at front. The present trailers have the exits at the front end and the entrance at the rear. Persons waiting for cars, however, usually congregate at the point where the rear end of the motor car stops and most of them pile on the crowded motor car rather than walk to the rear end of the trailer. The exit of the new trailer is next to the entrance and the conductor, standing behind a railing on the opposite side of the front end, opens and closes that door also.

Effective Measures to Protect Live Stock at Private Crossings.—With a view of reducing the liability from accident caused by livestock trespassing through private gateways left open by landowners, the Indianapolis & Louisville Traction Railway, Scottsburgh, Ind., mailed a circular letter by registered mail in June to all tenants and landowners along its lines. Since this letter was sent out an improvement has been noted in the state of repair of gates at private crossings and in their being kept closed. In addition the company has had several requests for padlocks, showing that the property owners are anxious to co-operate with the railroad in keeping the gates closed.

Albany Working Agreement Signed.—The working agreement between the United Traction Company, Albany, N. Y., and its employees on the Albany and Troy divisions has been signed by James F. Hamilton, general manager, for the company, and Joseph F. McLoughlin and Joseph Droogan for the men. No mention of increased wages is made in the agreement, as it was decided to await the outcome of the arbitration of this question on the properties of the New York State Railways. There is a provision in the new agreement, however, under which the men will be paid for every minute of the time they are on service after leaving the carhouse. All regular men are to be paid time and one-half for overtime.

Light Signals for Controling Traffic in Cleveland.—An electric traffic signal has been installed at East One Hundred and Fifth Street and Euclid Avenue, Cleveland, Ohio. The signal consists of four pairs of red and green lamps mounted on the tubular steel trolley poles, controlled from an electrically heated police booth placed on the sidewalk at the corner. In addition to the control switches for the signals, the booth also contains connections with the police and fire alarm circuits so that the street may be cleared for the rapidly moving emergency vehicles. Bell signals ring and red lamps appear in such emergencies. The work of developing the signals was done by the Cleveland Construction Company, and the installation was made by the American Traffic Signal Company.

Service Reduction Question in Cincinnati.—On Sept. 4 W. Kesley Schoepf, president of the Cincinnati (Ohio) Traction Company, called at the city hall in person to take up with the Mayor and Service Director Fosdick the question of reducing the service furnished by the company. He handed Mr. Fosdick a letter replying to the communication sent him by Mr. Fosdick in which the latter rejected the company's request to be permitted to take off a number of cars. Mayor Spiegel stated that he would at once have Chief Street Car Inspector Harry Wiesehahn make a detailed inspection of various lines, supplemental to that already made by him. In the meantime, he stated, he would permit of no reduction in service beyond that already made. This reduction includes the taking off of two cars on the College Hill line, two on Colerain Avenue, one on Seventh Street and one on Sixth Street. Mr. Schoepf assured the Mayor that he would comply with all orders, and would restore the service reduced whenever requested.

Accident Faker Arrested.—The Philadelphia (Pa.) Rapid Transit Company has succeeded in apprehending Frank J. Marter, twenty-nine years old, of Shermansdale, Pa., who tried to victimize the company through a fake accident. Marter has several aliases, being known as "Slim Jim," "Moter" and "Jones." In the confession which he made to officers of the Philadelphia Rapid Transit Company, Marter acknowledges having mulcted the Brooklyn Rapid Transit Company and the New York Railways. He also had a fake claim allowed against Fox's Fourteenth Street Theater, New York, for $500. Terry & Tench, New York, contractors were victimized for the sum of $300 and other companies for similar amounts. In Philadephia Marter pretended to fall from a train at the Fifth Street Station in the subway. He complained to a policeman, but instead of going to a hospital asked to be directed to a private physician. The following day he presented a claim for $1,500 damages against the company. It is said that Marter's right arm was broken when he was ten years old and that he had the peculiar faculty of throwing his arm out of joint at the elbow whenever he so desired. All his recent claims for injuries have been on account of this arm.

Personal Mention

Mr. Charles H. Armatage has resigned as traffic manager of the United Traction Company, Albany, N. Y.

Mr. M. H. Pengra, formerly superintendent of the Freeport Railway & Light Company, Freeport, Ill., is now in business at Eugene, Ore.

Mr. J. H. Brown has been appointed traffic manager of the San Francisco-Oakland Terminal Railways, Oakland, Cal., to succeed Mr. F. W. Brown.

Mr. U. S. Sliter has been placed in charge of the efficiency department of the San Francisco-Oakland Terminal Railways, Oakland, Cal., to succeed Mr. W. E. Hendley.

Mr. J. Q. Brown, formerly chief engineer for the San Francisco-Oakland Terminal Railways, Oakland, Cal., is manager for a new electric power company at Rochester, Nev.

Mr. W. V. Hunt, formerly electrical engineer of the British Columbia Electric Railway, Vancouver, B. C., has resigned from the company to enter private practice in that city.

Mr. A. Patterson, formerly electrical engineer with the Fort Smith Light & Traction Company, Fort Smith, Ark., is now general superintendent of the Southwestern Gas & Electric Company, with headquarters at Texarkana, Tex.

Mr. M. V. Knapp, for a number of years superintendent of the Pennsylvania Power Company at Ellwood City, Pa., has been transferred to the plant of the Mahoning & Shenango Valley Railway & Light Company at Youngstown, Ohio.

Mr. W. R. Alberger, formerly with the San Francisco-Oakland Terminal Railways, Oakland, Cal., has been appointed vice-president and general manager of the company to succeed Mr. A. W. McLimont, who retires from the company in accordance with the changes in the personnel, which are noted elsewhere in this issue.

Mr. George B. Tripp, vice-president and general manager of the Harrisburg Light & Power Company, Harrisburg, Pa., has become operating executive of the United Gas & Electric Company, New York City. He still acts as vice-president of the Harrisburg company, but has been succeeded by Mr. C. M. Kaltwasser as general manager.

Gen. F. E. Pierce, president of the Connecticut Valley Street Railway, Greenfield, Mass., has announced his candidacy for the Republican nomination of State Treasurer. Gen. Pierce had eleven years experience in the First National Bank of Greenfield, leaving that institution to become postmaster of Greenfield, which office he conducted for twenty years. Since its organization he has been president of the Connecticut Valley Street Railway. For more than twenty-five years he has served in the Massachusetts Militia, retiring a little more than a year ago with the rank of major-general. During the Spanish American War he commanded Company L of the Second Regiment and had a part in the battles of El Caney, San Juan, and Santiago de Cuba. For several years he was one of the Armory commissioners and is now president of the National Guard Association of Massachusetts.

OBITUARY

Frank A. Schwertner, of the Berger Manufacturing Company, Canton, Ohio, is dead.

Thomas E. Hughes, manager of the Philadelphia office of the Standard Underground Cable Company, died at his residence in Atlantic City, N. J., on Aug. 27. Mr. Hughes had long represented the Standard company throughout its Atlantic coast territory from Philadelphia south, and for the past seventeen years had been manager of its Eastern and Southeastern branch office sales department at Philadelphia. Mr. Hughes, while about to return from a visit to Bermuda for his health in the spring of 1913, suffered a stroke of paralysis from which he recovered sufficiently less than a year later partly to resume his regular duties. Prior to this connection with the Standard company, Mr. Hughes was connected with John A. Roebling Sons Company at Trenton and Scranton, and with the Washburn & Moen Manufacturing Company at Worcester, Mass., and Pittsburgh. He leaves a widow and two daughters.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Hamlin & Guyandotte Railroad, Hamlin, W. Va.**—Chartered in West Virginia to build an electric railway from Hamlin to West Hamlin, 5 miles. Capital stock, $50,000. Incorporators: L. R. Sweetland, J. S. Pridemore, L. M. Thacker and A. F. Morris, Hamlin; J. W. Dingess, Huntington, and George E. McComas, Milton, W. Va.

FRANCHISES

Los Angeles, Cal.—The Mayor and Council have authorized the Board of Harbor Commissioners to construct a single or double track railway from a point of connection with the tracks of the Pacific Electric Railway, northerly of Seventh Street, Wilmington, in the city of Los Angeles, and extending thence southerly across Seventh Street and along McFarland Street, to the intersection of McFarland Street with the northerly line of Tide Land Location No. 153.

Murphysboro, Ill.—The Murphysboro & Southern Illinois Railway has asked the Council for a thirty-year franchise on East Walnut Street, Twenty-second Street and Logan Street in Murphysboro.

***Hopkinsville, Ky.**—R. E. Cooper, Hopkinsville, has received a twenty-year franchise from the Council in Hopkinsville.

Methuen, Mass.—The Massachusetts Northwestern Street Railway has asked the Council for a franchise to relocate its tracks on Jackson Street in Methuen.

Portland, Ore.—An ordinance has been presented to the Council on request of the Portland Railway, Light & Power Company relieving the company from the requirements in its franchise to build a double-track railway on Twenty-sixth Street, from Thurman to Upshur, Upshur Street, from Twenty-fifth to Twenty-seventh, and Twenty-fifth Street, from Thurman to Upshur. These portions of streets are to be paved, and the company desires to lay only single tracks. Commissioner Daly has recommended that the ordinance be passed providing the company pays for the paving of the street which would be covered by a double track. It is understood the company has consented to do this.

Portland, Ore.—The franchise of the Portland & Oregon City Electric Railway will come up for final action in the Council about Sept. 15. The grant will allow the company the use of the streets in the southeast section of Portland and through a part of the downtown business district. It is proposed to run the cars into Portland along Tacoma Avenue. A provision of this proposed ordinance gives the city the right to order the company to change the location of its tracks whenever the city deems it necessary. This is the first time such a provision was ever contained in a grant for the use of streets.

Three Rivers, Que.—The Three Rivers Traction Company has asked the Council for a franchise to build an electric railway in Three Rivers. [E. R. J., Aug. 1, '14.]

Salt Lake City, Utah.—The Utah Light & Railway Company has received a franchise from the Council for a line from its terminus at Thirteenth Street East and Fifth Street South to connect with its line at Thirteenth Street East and Seventh Street South in Salt Lake City.

TRACK AND ROADWAY

Medicine Hat, Alta.—The Montreal Engineering Company having failed to carry out its agreement for the building of an electric railway in Medicine Hat, the agreement will in all probability fall through, and the company will be called upon to compensate the city for its failure to comply with the terms of the document. An extension of time for carrying out the agreement was granted to the company, but proceedings were taken against the Council to have the extension set aside, on the ground that it could not be valid without a by-law having been passed by the ratepayers. The action was finally defeated on technical grounds. The City Council is now negotiating with an Ottawa syndicate respecting the building of an electric railway under practically the same agreement as that made with the Montreal Engineering Company, and that a by-law granting a franchise will be submitted to the ratepayers at an early date.

British Columbia Electric Railway, Vancouver, B. C.—This company has been asked to extend its lines on Fifty-fifth Avenue between Victor Road and Kerr Road in Vancouver. A contract is reported awarded to M. J. Coughlan & Sons for the erection of a steel bridge across False Creek at Kitsilano, on the Eburne line, to replace the present wooden trestle, Vancouver, B. C.

Los Angeles (Cal.) Railway.—Right-of-way has been secured by this company for its proposed line through Schuetzen Park in Los Angeles.

Pacific Electric Railway, Los Angeles, Cal.—Work has been begun by this company laying new track on North Lake Avenue in Pasadena. Rather than pay for the paving on both sides of its private right-of-way on Las Tunas Drive in San Gabriel this company has notified the City Council that it will abandon its line on that street and turn over the strip of land owned by it to the city.

San Francisco, Cal.—The Board of Public Works has awarded the contract to Eaton & Smith for the construction of the municipal railway on Stockton Street from Sutter to Sacramento Street, this part of the line having been delayed to await the completion of the Stockton Street tunnel.

Murphysboro & Southern Illinois Railway, Murphysboro, Ill.—Within the next three weeks this company plans to begin work on its 8-mile electric railway between Murphysboro and Carbondale. Its power station and repair shops will be located at Murphysboro and it will furnish power for lighting purposes. Capital stock, authorized, $250,000. Officers: A. B. Minton, Murphysboro, president; C. H. Clay, 771 Clanton Street, Los Angeles, Cal., vice-president; W. C. Alexander, Murphysboro, secretary, and John G. Hardy, Murphysboro, treasurer. [E. R. J., July 18, '14.]

Taylorville Railway, Light & Power Company, Taylorville, Ill.—This company has surrendered its charter and dissolved.

Evansville, Chrisney & Eastern Railway, Evansville, Ind.—Plans are being made by this company to begin work within the next six weeks on its line from Boonville to Chrisney, Ind. Later on this line will be extended to Louisville, Ky., through Cannelton and Corydon, Ind. J. P. Chrisney, president. [E. R. J., Aug. 15, '14.]

Davenport & Muscatine Railway, Davenport, Ia.—During the next few weeks this company will award contracts to replace 3725 ft. of old track with new 70-lb. T-rails, new oak ties, rock ballast and 5-in. concrete brick face.

Keokuk (Ia.) Electric Company.—Work has been begun on the extension through the new McKinley Avenue district in Keokuk.

Hutchinson & Northern Railway, Hutchinson, Kan.—Plans are being considered by this company to build an electric line from Hutchinson east to Burrton and possibly Halstead, where connection will be made with the lines to Wichita. George Theis, Jr., president. [E. R. J., July 25, '14.]

Union Traction Company, Independence, Kan.—This company has placed in operation its new Coffeyville-Nowata interurban line between Coffeyville and Howden, Okla.

Consolidated Street Railway, Strong City, Kan.—During the next three weeks this company will be in the market for ten or fifteen tons of 45-lb. rails.

Arkansas Valley Interurban Railway, Wichita, Kan.—Arrangements have been completed by this company for the extension from Halstead to Hutchinson, Kan., connecting with the electric interurban systems out of Wichita. It is planned to use the tracks of the Hutchinson Street Railway into Hutchinson.

Springfield (Mass.) Street Railway.—The State Public Service Commission has issued three orders on the petition of this company for certificates preliminary to operation of sections of its railway in Springfield and Westfield.

Kansas City (Mo.) Railways.—Work has been started on the extension of the Prospect Avenue line of the railway northward from Fifteenth Street, and new tracks and routing will afford service to a large territory now inadequately supplied with tracks and cars. The new tracks will cross several east-and-west lines, and furnish a crosstown service to a considerable area. The board of control authorized the improvement, which will cost about $140,000.

Carbon & Stillwater Electric Railway, Red Lodge, Mont.—Preliminary arrangements are being made by this company to build its electric line between Red Lodge and Columbus, a distance of 40 miles. William Larkin, Red Lodge, is interested. [E. R. J., March 28, '14.]

Red Lodge (Mont.) Electric Railway.—This company, which plans to build an electric railway between Red Lodge, Washoe and Bear Creek, is still in the promotion stage. C. C. Bowlen, president. [E. R. J., March 21, '14.]

St. Johns (N. B.) Railway.—Plans are being considered by this company to extend its line through the Glen Falls subdivision as far as Manor House, St. Johns, N. B.

Poughkeepsie City & Wappingers Falls Electric Railway, Poughkeepsie, N. Y.—Work has been begun by this company on the construction of 2200 ft. of single track rock foundation with 7-ft., 70-lb. T-rails through certain streets in Poughkeepsie, replacing the 4-ft., 60-lb. T-rails.

Berlin & Northern Railway, Berlin, Ont.—Plans are being made by this company to extend its line from Bridgeport to Bloomingdale, Ont.

London & Lake Erie Railway & Transportation Company, London, Ont.—W. N. Warburton, general manager, stated that the company had in view a number of extensions of its lines, one being from London to Stratford, and that the company did not propose to ask for a franchise for city lines, but simply an entrance for a radial line, with a terminus at the Grand Trunk Railway station.

Port Arthur (Ont.) Street Railway.—A by-law was submitted recently authorizing the expenditure of $33,500 for street railway extensions.

Toronto Suburban Street Railway, Toronto Junction, Ont.—Construction was resumed by this company on the section of the Lambton-Guelph line between Lambton and Islington on Aug. 4.

Philadelphia (Pa.) Rapid Transit Company.—Work has been begun by this company laying new track on Chester Avenue, between Forty-ninth and Forty-second Streets in Philadelphia.

Hull (Que.) Electric Railway.—Plans are being made by this company to improve its lines in Hull.

Knoxville Railway & Light Company, Knoxville, Tenn.—This company is laying brick on Gay Street between its tracks from Commerce Avenue to the Southern Railway tracks in Knoxville.

Nashville, Tenn.—By an agreement with the Nashville Railway & Light Company, the City Commissioners have perfected plans for converting West End Avenue into a boulevard, with a broad parked space through which the tracks of the railway will pass, ornamental iron standards being erected to replace the trolley poles which are now in use along the thoroughfare. The cost, which will include condemning property on each side of the present roadway for a certain distance, will amount to about $42,000, and the city and railway company will share it equally.

***Nashville, Tenn.**—Extension of the interurban line projected from Nashville to Springfield, Tenn., into Kentucky, was announced as a part of the program of the promoters of the line at a recent meeting of the board of governors of the Nashville Commercial Club. The meeting was held to consider a proposition that the club endorse a subscription of $200,000 by Davidson County. The subscription would divide $200,000 of 6 per cent preferred stock among the subscribers. H. H. Mayberry is at the head of the new project.

***Castroville, Tex.**—Surveys are being made to build an electric railway to connect Castroville, San Antonio and Medina Lake. Subscriptions to the bonus list as well as the right-of-way are being solicited and meeting with great encouragement.

East Dallas, Tex.—Plans are being made to begin work at once on the electric railway along Parry Avenue from Kentucky Street to Carroll Avenue, and on Banks Street, ending at Henderson Avenue. This line will extend through the East Side in Dallas. John T. Jones, Dallas, is interested. [E. R. J., Aug. 29, '14.]

Greenville, Whitewright & Northern Traction Company, Greenville, Tex.—This company has changed its name to Greenville Northwestern Railway and plans to build an electric line from Greenville to Merrit and also from Greenville to Blue Ridge, Westminster and Anna and thence to Denton and Gainesville, Tex. A line from Westminster via Whitewright to Bonham is also planned. A. R. Nicholson, Greenville, president. [E. R. J., June 29, '12.]

***Glen Rose & Walnut Springs Railway, Walnut Springs, Tex.**—Grading has been completed and 1 mile of track has been laid by this company on its 14-mile line between Walnut Springs and Glen Rose. J. H. Farr, Walnut Springs, is interested.

Wisconsin Valley Electric Railway, Madison, Wis.—This company, which was organized in 1907 to build an electric railway from Grand Rapids to Stevens Point, has filed a notice of dissolution in the office of the Secretary of State. The company was capitalized at $25,000. The proposed line was not built. Henry F. Whitcomb, vice-president.

SHOPS AND BUILDINGS

British Columbia Electric Railway, Vancouver, B. C.—Work has been begun by this company in its new carhouses at Fourteenth Avenue and Main Street in Vancouver.

Northern Electric Railway, Chico, Cal.—Plans are being made by this company to build a new depot upon the northwest corner of the company's depot yards at the corner of Myers Street and Robinson Street in Oroville. The structure will be of wood, and it is expected that work will be begun within the next three months.

Toronto (Ont.) Civic Car Lines.—Plans have been prepared for the erection of a new carhouse at Hillingdon Avenue on the Danforth line in Toronto. The building will probably be 198 ft. x 199 ft., of brick and terra cotta on a steel framework. It will contain six tracks, and the offices will be in the wing at the rear end. Work is to be begun at once. The cost is estimated to be about $25,000.

Portland Railway, Light & Power Company, Portland, Ore.—The Milwaukee Commercial Club has petitioned this company to build an additional station on Washington Street in Milwaukee.

Austin (Tex.) Street Railway.—This company has moved its offices from the second floor of 113 West Sixth Street to the basement of 600 Congress Avenue in Austin.

Seattle (Wash.) Municipal Street Railway.—The Board of Public Works has awarded a contract to J. E. Crequer, Seattle, for the erection of a one-story carhouse for the Seattle Municipal Railway on the Lake Burien line.

Spokane & Inland Railway, Spokane, Wash.—Contracts have been awarded by this company to I. Abraham, Spokane, to build a new depot in Spokane.

POWER HOUSES AND SUBSTATIONS

Winona Interurban Railway, Warsaw, Ind.—This company has purchased from the Westinghouse Machine Company four Roney stokers for use in its boiler room of four 300-hp boilers at Winona Lake.

Maryland Electric Railway, Baltimore, Md.—This company will place in operation new substation equipment purchased from the General Electric Company consisting of a 2000-kw rotary converter, three 750-kva transformers and switchboard.

Mahoning & Shenango Railway & Light Company, Youngstown, Ohio.—This company's substation in Lowellville was destroyed by fire on Sept. 2.

Nashville Railway & Light Company, Nashville, Tenn.—This company has placed an order with the General Electric Company for a 6000-kva cooled transformer, switches and accessories for its power plant in Nashville.

Greenville & Northwestern Railway, Greenville, Tex.—Plans for the construction of a new power plant in Greenville are well under way.

Manufactures and Supplies

ROLLING STOCK

Winona Interurban Railway, Warsaw, Ind., expects to purchase one freight car body for express and freight service.

Devil's Lake & Chautauqua Electric Line, Devil's Lake, N. D., expects to purchase one storage-battery car about March 1, 1915.

Portland, Eugene & Eastern Railway, Portland, Ore., has ordered one electric locomotive for operation on its branch between Oswego and the paper mills of Oregon City, Ore.

Port Arthur (Ont.) Street Railway has been authorized in a by-law passed by the rate payers of Port Arthur to purchase at least four new street cars at a cost of $22,000.

Santiago (Cuba) Tramways reports that it has not recently ordered rolling stock from any car builder as it constructs all its cars in its own shops, of special wood grown in Cuba.

Boston (Mass.) Elevated Railway, noted in the ELECTRIC RAILWAY JOURNAL of Aug. 22 as expecting to purchase thirty-seven center-section bodies for articulated cars, has ordered this equipment from the Laconia Car Company.

Winnipeg (Man.) Electric Railway will adapt its entire stock of cars for pay-as-you-enter service. City Traffic Supervisor Lewis reported to the Board of Control on Aug. 1 that this would necessarily take some time. There were on that date thirty-three pay-as-you-enter cars in operation in the city.

London (Ont.) Street Railway has ordered four single-truck pay-as-you-enter cars from the Preston Car & Coach Company, similar to those ordered last year and added to the company's equipment during this year. The company has also decided to remodel four large open cars so that they will be suitable for winter service, and yet be convertible to open cars at a small expense. It has also been decided to remodel the older cars to the pay-as-you-enter system as rapidly as they can be spared from the service.

TRADE NOTES

Pyrene Manufacturing Company, New York, N. Y., has appointed C. L. Allen, formerly automobile sales manager, as general sales manager of the company.

Rooke Automatic Register Company, Providence, R. I., reports the recent installation of its system of fare collection on all cars operated by the Lehigh Traction Company, Hazelton, Pa., and the Monmouth (N. J.) County Electric Company.

Frank F. Fowle, consulting engineer, New York, was recently appointed one of the receivers of the Central Union Telephone Company, with headquarters in Chicago, and was obliged for this reason to close his New York office as consulting engineer at 68 Maiden Lane and move his headquarters to Chicago. The Central Union Telephone Company extends over Ohio, Indiana and Illinois, and the executive duties in connection with this system require practically the entire time of Mr. Fowle for the present. He intends to resume his work in consulting engineering after the conclusion of his duties as receiver.

General Electric Company, Schenectady, N. Y., has recently received the following orders for electrical equipment: Morris County Traction Company, ten GE-200, 40-hp, four-motor car equipments; Connecticut Company, twenty Type MK, double-end control equipments; Steubenville & East Liverpool Railway & Light Company, four GE-200, 40-hp, four-motor car equipments with MK-control equipments, and air-brake equipments with CP-27 compressors; Pier Railway, four GE-200, 40-hp, two-motor car equipments; Southern Traction Company, eleven GE-203, 50-hp, two-motor equipments; Mahoning & Shenango Railway & Light Company, forty GE-247, 30-hp railway motors and ten emergency straight air-brake equipments; Portland, Eugene & Eastern Railway, three GE-205, 110-hp, 1500-volt, four-motor equipments; Third Avenue Railway, fifty GE-247, 30-hp railway motors; San Antonio (Tex.) Traction Company, eleven GE-200, 40-hp, four-motor car equipments; Sacramento Electric, Gas & Railway Company, eight GE-203, 50-hp, two-motor car equipments with K-36 controllers.

ADVERTISING LITERATURE

Prepayment Car Sales Company, New York, N. Y., has issued a folder entitled "Royalty."

Drew Electric & Manufacturing Company, Indianapolis, Ind., has issued a sheet which lists its various kinds of line material.

Transmission Engineering Company, Pittsburgh, Pa., has issued a folder describing its weatherproof oil circuit breaker for 2500 volts.

American Blower Company, Detroit, Mich., has issued Bulletin No. 27 describing an installation of its system of heating and ventilation.

Oakley Chemical Company, New York, N. Y., has issued a catalog describing its cleansing product, "Oakite" for use in cleaning cars and locomotives.

Canton Foundry & Machine Company, Canton, Ohio, has issued a folder describing its new portable floor crane and hoist for heavy lifting in car and repair shops.

Roto Company, Hartford, Conn., has issued a series of catalogs describing its Roto tube cleaners. Catalog No. 41 describes boiler tube cleaners driven by air or steam; No. 42, water driven cleaners; No. 43, cutter heads for boiler tube cleaners; No. 45, safety tube cleaners for fuel economizers; No. 48, condenser tube cleaners for copper tubes.

National Scale Company, Chicopee Falls, Mass., has issued a folder describing its Multicall, a code-calling system used with or without a telephone system, by which instant communication may be obtained with any one in a business establishment without disturbing or annoying delays to disinterested parties, thus eliminating the daily waste of minutes that accumulate in many lost hours yearly in an effort to locate some one in the plant.

Chandler Brothers & Company, Philadelphia, Pa., have recently issued a special letter containing general financial information regarding the General Electric Company. A résumé is given of the company's history from the standpoint of intercorporate relations and physical growth, and a discussion is presented commending the company on its policy in regard to earnings and dividends. At the end of the letter there is a statistical summary showing, among other features, approximate dividend dates, a comparative table of annual reports and general balance sheets, and a list of high and low stock prices.

American Engineering Company, Philadelphia, Pa., has issued a handsomely colored catalog on its gravity underfeed stokers. In the case of these stokers coal is fed beneath the burning fuel instead of upon it, as with the hand-fired furnace or natural draft stokers. The fuel bed is inclined and the refuse from the fuel flows automatically out of the ignition zone as soon as released from the carbon. The catalog describes the design and operation of the stoker and shows its results in labor economy, low maintenance, smokelessness, fuel saving, overload capacity and flexibility. A number of large illustrations show representative installations, among which are included those of the Boston (Mass.) Elevated Railway, Northern Ohio Traction & Light Company, New York, New Haven & Hartford Railroad and Elmira (N. Y.) Water, Light & Railroad Company.

Universal Lubricating Company, Cleveland, Ohio, has issued a folder describing its lubricant "Tulc," adapted for use in connection with roller and ball bearings, compression cups and air compressers, hydraulic presses and pumps, armature and motor axle bearings, trolley wheels, cranes, hoists, and conveying machinery, jacks, air brakes and pneumatic tools. This material is a petroleum product carrying sufficient pure, fatty substance to make it a suitable lubricant on bearings carrying either heavy or light loads and under conditions of extreme heat or cold. This substance is said to contain the advantages of both oil and grease as a lubricant by eliminating the wastefulness of running oil and the necessity of becoming heated before lubricating qualities are available, as in the case of grease. The manufacturer asserts that this lubricant will not harden or gum and that it leaves no residue, contains no acid or filler, will not corrode metal or grow rancid, and that it prevents rust.

Vol. XLIV NEW YORK, SATURDAY, SEPTEMBER 19, 1914 No. 12

PAPERS IN THE CONVENTION PROGRAM

Two weeks ago we printed in full the program of the coming convention of the American Electric Railway and affiliated associations for the purpose of stimulating interest in the convention. The program indicates clearly the tendency of the association to concentrate attention upon committee work. This year the total number of papers scheduled on the program is not more than fifteen for all of the associations, ranging from five for the American to none for the Engineering Association. On the other hand, the total number of committee reports is more than sixty, including six joint committee reports. The American Association leads in number of reports with twenty-one. As compared with last year there are about 25 per cent more committee reports and 40 per cent fewer papers. This is a sign of the times, and especially a sign of healthy activity in the association. The change is being brought about not because committee reports are more interesting than addresses but because several hundred specialists have been doing steady work during the year, and they want to get the sanction of the association to their recommendations so that their work can become effective in improving the status of the industry. There is no danger that an association will go to sleep when a reasonable proportion of the members are actively engaged in committee work.

CAN COMMITTEE WORK BE OVERDONE?

The tremendous expansion in the Associations' committee activities carries with it a real danger. A too elaborately organized committee machine may continue to grind out reports because such reports are expected, whether there is really anything to report upon or not. Again, committee appointments in a society are apt to be looked upon as honors as in legislative bodies, and where this is the case it is very difficult to get effective work done. The members of an association have a right to expect results from committee work, and if an existing committee is "marking time" it should either be honorably discharged if it has accomplished what it was appointed for, or revamped if it has failed to appreciate the opportunity which it had for useful work.

LIFE OF ALL-STEEL CARS

One of our readers has called our attention to the question of life of steel cars, stating that one of the real reasons for using steel construction is to obtain a reasonably light car which will give maximum life at a minimum operating cost. This belief is interesting if it is sound. We, on the other hand, are of the opinion that the growing demand for the all-steel car is due to its lightness and low maintenance cost, and, in many cases, to its low first cost as well. Its physical life hardly seems to be an important factor, although the belief is prevalent that a steel car should have even a considerably longer life than a car which is built of wood. As a matter of fact it may be safely said that all cars which escape fire and disastrous wrecks are obsolete long before the end of their normal lives. The lapse of fifteen or twenty years time brings far-reaching improvement, even revolution, in design, and practically any kind of construction with reasonable care will last as long as that. Indeed, the introduction of the prepayment idea nine years ago has alone rendered obsolete most of the earlier cars, and the desire to avoid scrapping the many small single-truck units of eighteen or twenty years ago that are still in good physical condition has involved the most elaborate and ingenious rebuilding schemes. To design, advisedly, a car for a fifty-year life when it will be obsolete in twenty years seems hardly less than the veriest folly.

SOUTH AMERICAN BANKING

The recent decision of the Federal Reserve Board authorizing the National City Bank of New York to establish branches in Buenos Aires and Rio de Janeiro marks the official entrance of American banks into a hitherto undeveloped field. We hope the expectation that the new banking machinery will be put into operation at the earliest date will be soon realized, for there is no time for delay. We need a little of that creative force of easy banking, credit and investment facilities that has been so indispensable to European commercial success. The complete organization of the two new branch banks will help the expansion of credit-acquiring facilities that have been hampered by the requirements of gold deposits in the banks, but the successful completion of all stages of the work will require arduous and persistent effort on the part of more than one American bank. Already urgent pleas are coming from Ecuador and Chile for American financial institutions. That an excellent opportunity exists for improving all commercial conditions with South America is indicated by the action of the Dutch in forming the Banco Hollandese de la America del Sud to help build up Dutch trade in Argentina. This is the first Dutch overseas banking house, except those in the Dutch East Indies and the Far East, and its institution at the present time shows the importance of American banks taking immediate steps to grasp the opportunities offered.

THE RAILROADS' APPEAL While the brief presented to President Wilson last week by a committee of steam railroad executives points out as paramount the vast increase in railroad expenses, the really notable features of the carriers' arguments concern the maintenance of railroad credit and the direct appeal on this point to the American public. The problem of raising new capital for improvements and extensions or for refunding purposes, except at increased interest rates, is one now confronting not only the steam railroads but also the electric railways. Financial prosperity, seriously impaired before the European conflict, is now face to face with an emergency of unparalleled magnitude. Each day of the war adds to the destruction of capital, and even now, as shown by the 6 per cent rate on the New York City loan, all nations are entering the period of higher interest rates caused by poorer credit conditions and a keener competition for capital. Such conditions will affect electric railway financing as well as that of steam railroads, and the net earning power of each class of lines must be increased to cover the additional cost of capital. President Wilson in answering the steam railroads' appeal has called the attention of the public to the necessity of co-operation with and sympathy for the steam railroads. The effect of this is as yet undeterminable, but it is the hope of electric railways that this relief will be granted, for then governors, state legislatures and state commissions may be moved by example to allow electric railway earnings commensurate with present conditions.

TOLEDO SEES THE LIGHT

The injunction order of Judge Killits in the Toledo case is by far the most encouraging development in the long contest conducted by Mr. Doherty for a fair franchise ordinance. To say that it means the turning of the tide of public opinion after so lengthy a controversy may appear to be an over-jubilant conclusion; but the fact cannot be ignored that it immeasurably improves both the legal and the moral position of the company.

The action of the court in issuing an injunction which was denied in an earlier proceeding some months ago, the acceptance of the spirit of the injunction by the public, the candid admission by the city solicitor who contested the application for an injunction of his discovery that the 3-cent fare ordinance was fathered under the previous administration by "political trickery" and, lastly, the plan to reopen negotiations for an equitable franchise are the most eloquent signs of a revolutionary change.

From the beginning, the fight at Toledo has been conducted with the desire to reach public opinion, to show the whole public the facts and in that way to gain direct support for a workable franchise. Toward that end all of the personal efforts of Mr. Doherty were directed, and in his work he had the loyal support of the company officials and employees, clear through to the rank and file. He made his headquarters in Toledo, he wrote interesting, convincing articles full of human touches which were published in the newspapers, and he both talked informally and spoke formally in regard to his plans. The city officials openly encouraged people to ride free, if they could not ride for 3 cents, and the company as openly invited people to ride free if they would not pay the fare provided in the temporary arrangement. Some of the daily newspapers were hostile. In a community where such influences had existed and grown strong Mr. Doherty was a new, untried and novel element. The burden of the attack shifted from the company to him, and he shouldered it. Publicly he has confidently expressed the opinion again and again that a new franchise at a fair rate would be granted because in the end nothing else would suit the needs of the people for transportation and, if they knew the truth, meet the idea of fair play.

It is difficult to trace the influence of all of these circumstances upon public opinion, which is full of surprises and inconsistencies. From the company standpoint the facts underlying the Toledo situation are substantially the same now as they were some months ago. The company showed then, to the complete satisfaction of the accountant selected by the city, that it could not operate at a 3-cent fare and make any return on the investment. It shows that now. People did not accept the showing then or, if they did, they failed to indicate that they accepted the inevitable conclusion. The people, in increasing numbers, do accept the showing now. The reasonable deduction from these conditions is that public opinion has changed.

The decision of Judge Killits, which is published in full elsewhere in this issue, is strong. The city executive neglected the "only proper method of enforcement" of the 3-cent ordinance, which would have involved decision of the company contention "that it was oppressive and unreasonable." In suggesting that the city's power would be used to assist individuals who attempted to ride at 3 cents, the city officials occupied a "wholly indefensible position." "It is to deal with precisely" such situations that courts of equity are open. Judge Killits then mentions a point that is frequently overlooked in these days, that the corporation, like the individual person, "is under the protection of the guaranties of the federal constitution."

In the text of his decision Judge Killits is severely critical of the action of the city executive. The testimony shows without dispute that, when the 3-cent ordinance was passed and signed, that official was "possessed of statistical information in most illuminative detail from the city's trusted expert, which, properly considered, showed that a 3-cent fare was confiscatory." Why the city, ignoring this unanswerable fact, proceed on the road toward confiscation the decision does not discuss. We are not sure that it has been known generally that the city expert, "in advice privately given in writing and orally" to the executive, showed that the 3-cent ordinance should not be passed. That is a scathing indictment of the city attitude. The city purposed to have 3-cent fares without regard to the question of whether or not they were confiscatory. Does public opinion approve of that dishonest course?

The revelation by the city solicitor of the fact that various members of the previous city administration had been apprised of the impracticability of the 3-cent ordinance and his admission that political trickery fathered it do not wholly atone for the grievous wrong done to the company, but they serve the good purpose of showing the animus of the movement. Confession is always good for the soul. The duty of the city officials now is to take up in earnest the work of negotiating a new, reasonable and fair franchise that shall both protect what property the company has and invite outsiders to put more money into additional property. Only by encouraging capital can Toledo hope to have the public utilities that a growing city needs. Toledo has had its experience, costly in time and harmful to the company, with a confiscatory rate of fare. How great the cost is can never be told, but some compensation will arise from it if the result shall be an ordinance that is not only fair to the company and public but that is also a lesson against unreasonable attacks and a lesson that promotes just treatment. If public opinion is determined on a square deal the end of the discreditable Toledo controversy is, if not in sight, just behind the negotiations for a new franchise that will now be started.

RESULT OF INSERT SPECIAL WORK STUDY

The study of insert special work presented on another page in this issue, it is believed, has been sufficiently exhaustive to make the discussion of the causes of and cures for the various forms of failures conclusive. From it we are satisfied that if track and roadway engineers will give the track structure real engineering consideration and will analyze the conditions under which each installation must serve, the life of all types of special work will be greatly increased. In the past, too little attention has been given to the proper choice of special work, the requirements often being only that it would fish with the track rails while the design and materials were left to the manufacturer who was the lowest bidder. It is hardly necessary to say that there is a great difference in the wearing qualities of the various types of insert fastenings and body casting construction under different classes of service. Certain designs are especially suited to certain classes of service, and not to others, and it is just as important to select the design for the work to be done in track work as it is of any class of engineering structure.

The first lesson derived from this study of insert work is that no matter what type of frog or switch piece has been adapted it has cost enough money to justify the purchase of a special set of ties and the preparation of a first-quality foundation to receive it. As mentioned in the article, these ties should be arranged to permit thorough tamping at the time of installation as well as later, when resurfacing is required. More care must be exercised in the selection and spacing of the ties and preparation of the foundations under iron-bound work than under cast-steel arm work, especially when the service includes heavy interurban cars. In either case, however, the installation must be followed by diligent maintenance.

While the life of insert work depends to a large extent upon the care with which it is installed, another factor of equal or greater importance is the care exercised in the manufacture and choice of materials by the maker. For cast-iron bound work, he must provide a casting of sufficient cross-section to insure its ability to stand up under the traffic it has to bear. He should know what service each installation is to perform and recommend a design in accordance. It is believed that the various processes used in toughening the casting against transverse bending strains in the present types of iron-bound insert work are good. They have tended to reduce broken castings to a minimum under street railway traffic, but there is yet room for improvement in the class of special work which is furnished to interurban lines.

Modern heavy traffic conditions such as exist in large cities in congested districts or on interurban roads demand a change in many types of insert fastenings and settings. Large railway companies meeting these conditions successfully and economically with inserts supported strictly on a spelter bed are indeed fortunate. In the past, under light traffic conditions and light cars, the loose insert was an exception to the rule. To-day this form of defect has done more than any other to cause engineers to look with disfavor on the insert type of special work.

An inspection of a large number of layouts under various conditions gives positive proof to the fact that numerous loose inserts are not common to all classes of settings and fastenings. Bolted-down or keyed-down inserts on partially or completely machined bearings are believed to be necessary to meet many present-day heavy traffic conditions. If the former type is employed, treated 1-in. bolts or their equivalents should be used, and the heads and nuts should be securely locked in position. In case the keyed-down insert fastening is employed some method of locking the keys should be provided.

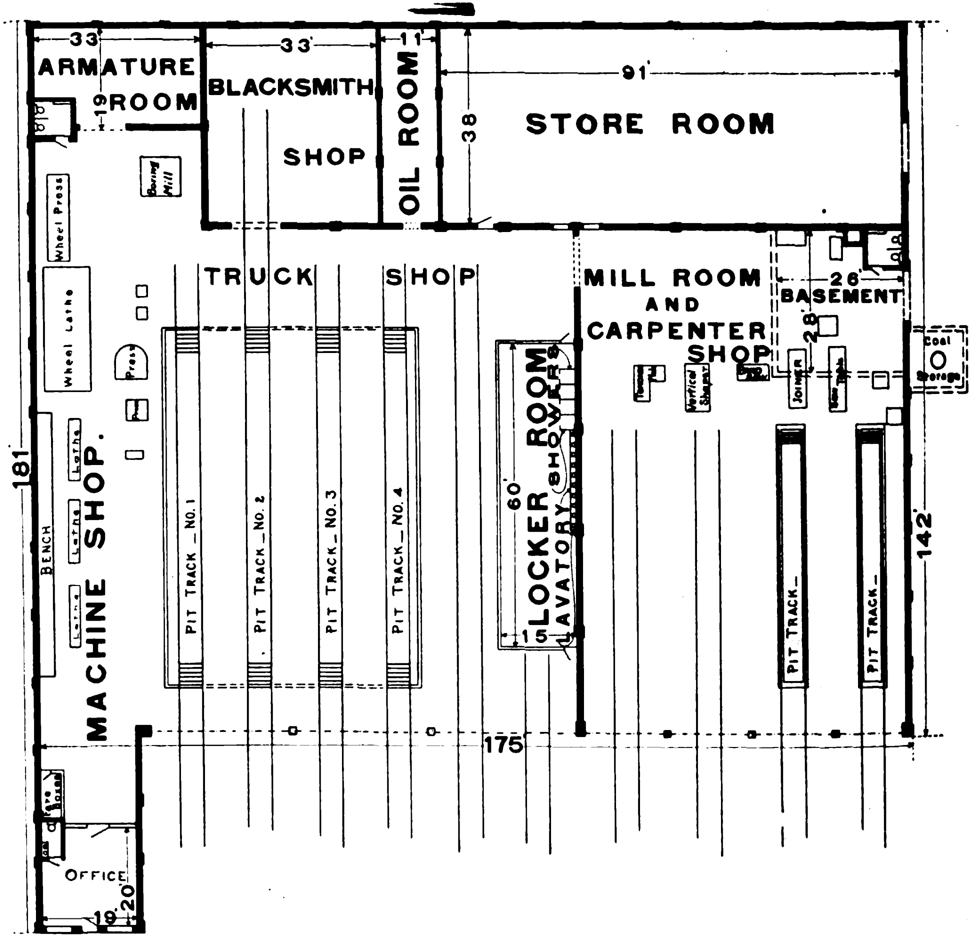
It is hoped that neither the article nor this editorial will lead anyone to believe that insert special work is a failure in track special work. As a rule we believe that it has been giving excellent service, but it has been, and still is, in a developmental stage, and it is hoped that this analysis of existing conditions will be productive of improvement. Lack of complete information on the part of railway engineers and manufacturers has led to dissatisfaction on the part of both. Moreover, some of the failures which have been attributed to workmanship and material are properly chargeable to dilatory maintenance. The remainder are due to improper choice of design from a service standpoint, in conjunction with an insert fastening and setting which is not strong enough mechanically to meet the heavy traffic conditions which prevail on street and interurban railways.

New Repair Shops of Dallas Street Railway

This New Shop Building Embodies Many Features in Design and Compact Arrangement Which Are Well Worthy of Attention

Compactness and convenience of layout, as well as the attention that has been given to the design of the building to obtain efficient lighting and ventilation, are the noteworthy features of the new shops of the Dallas Consolidated Electric Street Railway Company of Dallas, Tex. This shop building was completed recently and is located just outside the business district, thus minimizing dead mileage from the operating divisions. In addition, this location is peculiarly convenient since the main carhouses of the company are just across the street so that the dead mileage in moving cars from the carhouse to the shop for repairs is very small.

The present development includes machine shop, truck shop, blacksmith shop, store room and oil room, all under one roof. The company plans, in the near future, to erect another similar but somewhat smaller building to serve as a paint shop, alongside the carpenter shop, but separated by a 14-ft. alley from it. For the present the painting will be done in the rear end of one of the storage bays across the street from the new shop building. Adjacent property owned by the railway will permit future additions to the present building and will be utilized as necessity may require. The present layout, however, with the contemplated new paint shop, was believed of ample capacity for some years to come.



DALLAS REPAIR SHOP—FLOOR PLAN OF CAR SHOPS

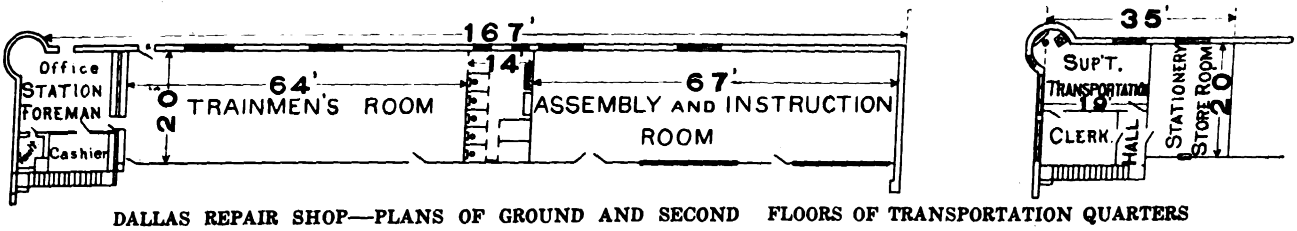
GENERAL ARRANGEMENTS

Reference to the plans of this new repair shop clearly indicate the compactness as well as the convenience of arrangement. In order to provide open storage space for cars between the sidewalk and the shop entrances, the building was set back 39 ft. The area in front was paved and the shop office, which adjoins the machine shop, was allowed to jut out to the sidewalk line. Ten tracks enter the shop building and connect into a special ladder track which parallels the double track in the street in front of the building. By this arrangement the use of a multiplicity of frogs and switches in the main track was avoided. This entire track layout was built of 108-lb. 6-in. girder-grooved rail with cast-steel frogs and switches, and the ladder approach was connected to the main track only at one end.

In adopting the general shop arrangement, special attention was directed to continuity of movement of work through the shops, as well as to the elimination of fire hazard. The machine shop and armature room occupy one side of the building, the former being a part of the truck shop and the latter, although completely enclosed, adjoins both. The blacksmith shop at the rear end of the truck shop is also fully enclosed by brick walls and adjoins the oil room, but is separated from it by a fire wall. At the side of the oil room and occupying a part of the rear of the truck shop, as well as the carpenter shop, is the storeroom. This location is convenient for all shop departments and the storeroom is fully enclosed by brick fire walls. A brick partition wall also separates the two main shop bays, that is, the truck shop and the carpenter shop.

STRUCTURAL DETAIL OF BUILDING

The building walls are constructed of common brick in cement mortar with the exposed walls laid with red-faced brick. All walls are 13 in. in thickness with 17-in. pilasters, and were built upon 19-in. reinforced concrete foundation walls. Between the pilasters of the outer walls, except in the storeroom, are windows 11 ft. x 13 ft. in size. These windows are glazed with ¼-in. wire-ribbed glass set in United States steel sashes, arranged three in a section. The outer walls of the storeroom have only single section windows between pilasters. These windows are just below the roof line, so as to give light and ventilation and still be inaccessible to persons from the outside. In the shop proper the large windows have the top and bottom sashes pivoted, so that they may be opened wide to afford plenty of air circulation, which is absolutely necessary to provide good working quarters during Texas summer heat.



DALLAS REPAIR SHOP—PLANS OF GROUND AND SECOND FLOORS OF TRANSPORTATION QUARTERS

Mill construction was used in framing the roof, which was built of long-leaf yellow pine and covered with Philip-Carey felt roofing. Skylights over each pit, in conjunction with a liberal spacing of windows, insure ample natural illumination in the remotest parts of the building, even on the darkest days. Car entrances are 19 ft. high x 16 ft. wide, and are enclosed with hand-operated Kinnear rolling steel doors. These rolling doors are installed between the lattice steel columns which support the face of the building. During the warm summer months the raising of these doors opens up the entire front of the building and, in conjunction with the open pivoted sashes, provides the maximum amount of light and air.

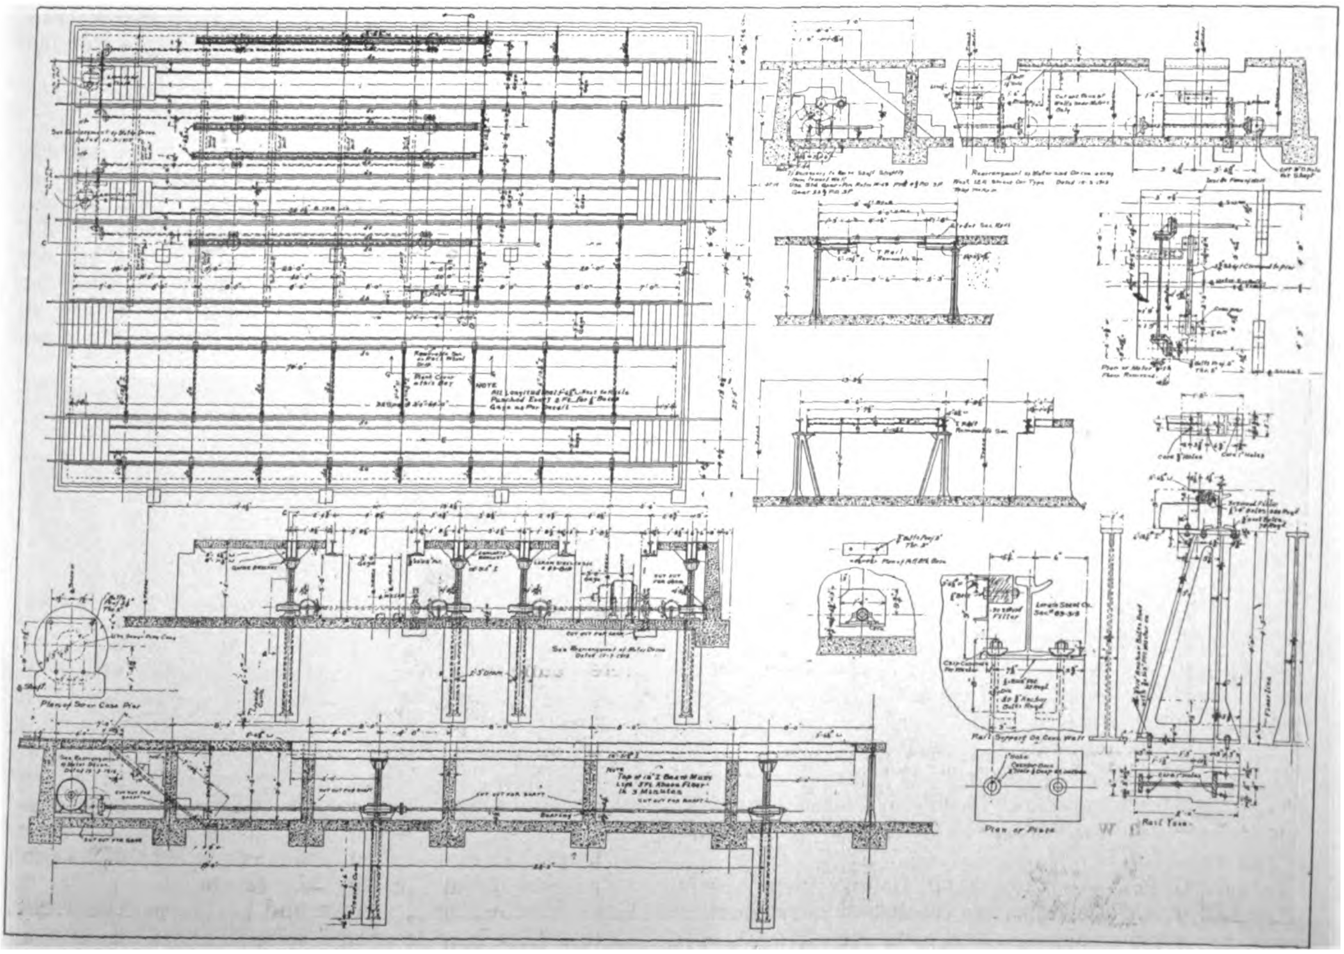
The machine shop and armature room have creosoted wood-block floor, laid on a 6-in. concrete foundation. Other floors except the blacksmith shop, which is cinders, are of concrete. The surface of the concrete floors was hardened with the "Master Builder process," which is nothing more than iron filings and dust worked into the floor wearing surface to increase its abrasive resistance, to obtain a surface of maximum durability.

MACHINE SHOP

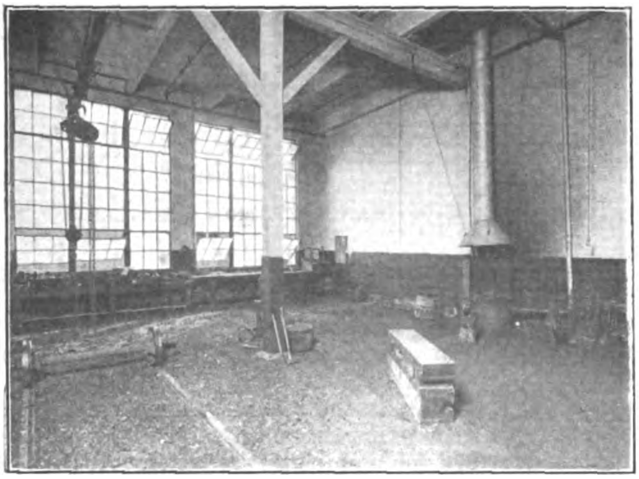
The machine shop, which is 20 ft. x 139 ft. in size, is equipped with all of the tools necessary in modern car repairing, such as wheel lathe, wheel press, wheel boring mill, drill presses and machine lathes. The wheel presses and wheel lathe have individual motor drive, while the other machines are driven from line shafting which is connected by belt to a 40-hp, 600-volt, d.c. motor. Immediately in the rear of the master mechanic's office, which adjoins the machine shop, an enclosed space is provided for repairing fare boxes. At the rear of the machine shop is the armature room. It is equipped with an armature-banding machine, armature rack and work benches. Both of these departments have creosoted wood-block floors, which is believed to have a distinct advantage over other flooring material in that it is easier on workmen while standing, and does not scar when heavy material is dropped upon it or rolled over it.

BLACKSMITH SHOP AND OIL ROOM

A well-lighted and ventilated room, 33 ft. x 38 ft. in size, forms the blacksmith shop. Practically the entire west wall of this shop is occupied by windows, while a 10-ft. door provides access to the main shop. The blacksmith shop is equipped with two forges connected to a centrifugal fan, which in turn is belted to the shop line-shafting. This air-blast connection is through 4-in. supply pipes to the forges.



DALLAS REPAIR SHOP—DETAILS OF PIT SECTION IN TRUCK SHOP



DALLAS REPAIR SHOP—MILL ROOM AND CARPENTER SHOP

DALLAS REPAIR SHOP—VIEW OF STORE ROOM

Beside the blacksmith shop is the oil room, which is 11 ft. x 38 ft. in size. This room was placed next the storeroom so that the storekeeper can conveniently handle the oil stock as well as other storeroom materials. The various oils are stored in Bowser metal tanks equipped with self-measuring pumps. By means of these pumps it is believed that the wasting of oil will be largely eliminated, and at the same time a very close check of its use will be obtained. All paints and varnishes are also stored in the oil room, which is provided with only one entrance, that being on the side toward the main or truck shop.

TRUCK SHOP

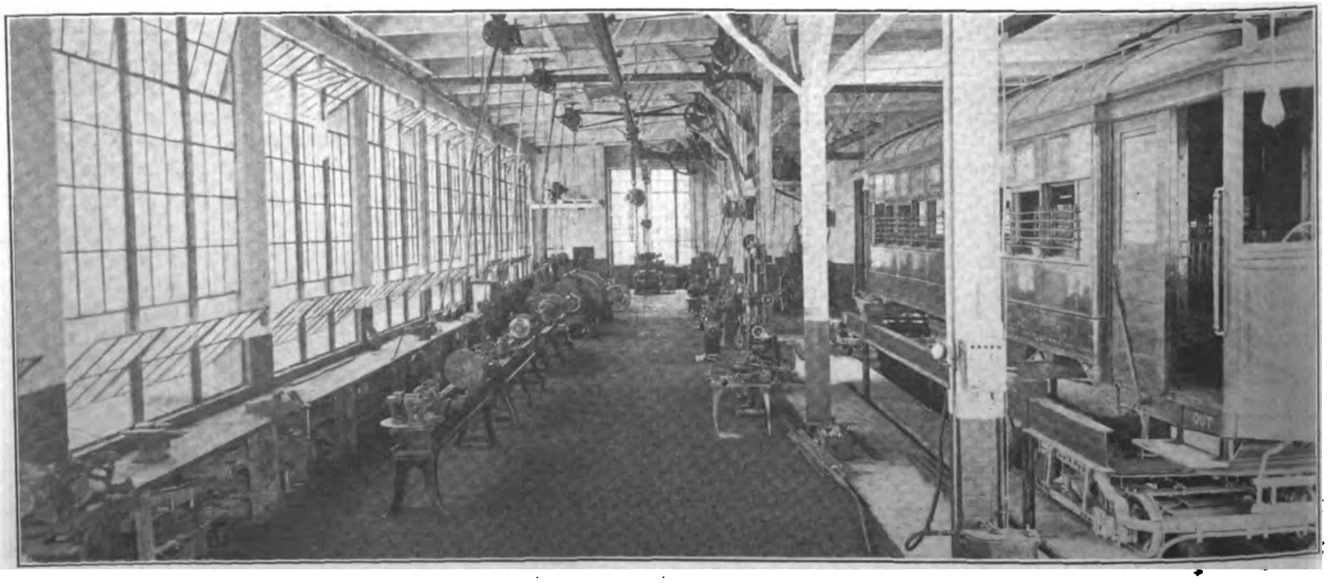
The truck shop has four pit tracks and two tracks without pits. The four pit tracks pass over one large pit which is 70 ft. long by 50 ft. 5¾ in. wide and 4 ft. 5 in. deep, measured from the floor line. The rails over the pits are 91-lb. 9-in. girder-grooved rail, two of the tracks being supported on cast-iron yokes while the other two tracks, which are equipped with car hoists, are supported upon concrete piers. The details of the construction of these pits and car hoists are shown in the accompanying illustrations.

Tracks 1 and 2 are equipped with pit car hoists, arranged for individual motor drive, with worm-and-gear and continuous-shaft connections. Track 3 has a 4-ft. 6-in. removable section of rail which permits wheels to be dropped from trucks into the pit with the assistance of an air hoist. All four of these tracks over the pits extend 20 ft. beyond and upon the shop floor, except track 2 which extends into the blacksmith shop, so that trucks may be rolled direct from under the car body into the blacksmith shop.

An overhead trolley hoist, running upon 8-in. I-beams and having a capacity of 3 tons, serves each of the truck-shop tracks, the blacksmith shop, the armature room and the machine shop. The arrangement of the hoist runway is such as to facilitate the conveying of repair parts from the pits and floor of the truck and blacksmith shops to any machine in the machine shop. The arrangement of these runways may be seen by reference to illustrations showing the machine shop and truck shop. Instead of using trolley wire over the tracks in the shops, 3-in. T-iron was placed in wooden troughs for this purpose. This kind of an overhead installation, it was believed, would be more durable than wire and less liable to break.

LOCKER ROOM AND LAVATORY

A locker room and lavatory, 15 ft. wide, extends along the partition wall between the truck shop and the carpenter shop for a distance of 60 ft. This location, however, is only temporary, as it is planned to build a second story over the store room for this purpose whenever it becomes necessary to occupy this space for shop use. On account of its temporary nature an 8-in. brick wall, 10 ft. high, was erected to screen



DALLAS REPAIR SHOP—INTERIOR OF MACHINE SHOP BAY the lockers and lavatory from the shop. The lockers are of the expanded-metal type, one being provided for each workman. In this room also are four shower baths and ten porcelain wash basins provided for the convenience of the employees.

Carpenter Shop

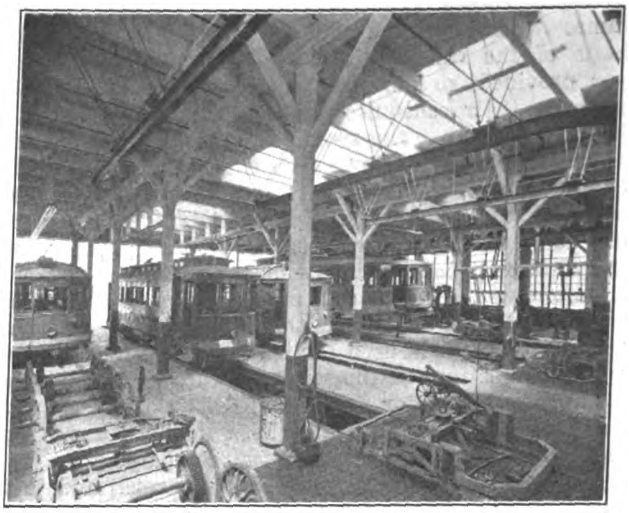
The carpenter shop, which is separated from the truck shop by a brick fire wall, is provided with four tracks 60 ft. in length, two of which pass over repair pits. These pits are built with reinforced concrete walls and are 50 ft. long. The mill machinery in this department is located at the end of the tracks where it is convenient to them. Under a portion of the carpenter shop is a 26-ft. x 28-ft. concrete basement. In this is located an automatic gas heater for hot water, and it will also provide space for the shop heating plant. It is planned to install a hot-air blower heating system which is believed to be best adapted for the purpose in a climate which changes quickly from hot to cold and vice versa.

Store Room

A store room with ample headroom and floor space, and easily accessible to all departments of the shop, is provided at the rear of the carpenter and truck-shop bays. Its central location will result in a minimum loss of time by employees going to and fro after material. A 10-ft. door, opening into the alleyway at the rear of the building, permits material to be unloaded from trucks and wagons directly upon the floor of the store room. All doors in the store room partition walls, as in the walls in the remainder of the shop, are equipped with automatic fire doors furnished by the Gilbert Manufacturing Company, of Dallas, and approved by the national board of fire underwriters. Artificial illumination in the store room as in the other shop departments is by the direct system, drop lights being placed so as to furnish uniform illumination. All wiring is exposed, but installed in conformance with the underwriters' code.

Fire Protection

The entire shop building is protected from fire by a Grinnell automatic sprinkler system, which required the erection of a 50,000-gal. steel tank set upon a latticed steel tower, 100 ft. above the ground. This tank also serves for automatic fire protection in the carhouses, across the street from the repair shop building. In addition to, and at the same time serving, this tank is a two-stage, 7-in. centrifugal pump, with a capacity of 750 gal. per minute at pressure of 100 lb. per square inch.



DALLAS REPAIR SHOP—INTERIOR VIEW OF TRUCK SHOP AND INSPECTION PITS

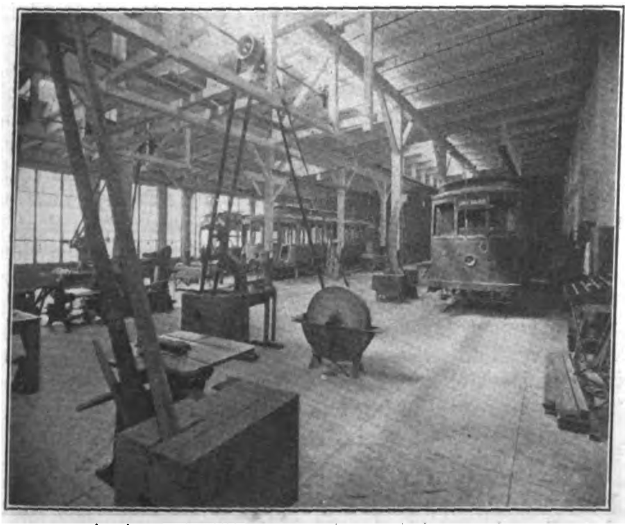
New Transportation Quarters

In connection with the erection of the new shop building, the transportation quarters of the company have been enlarged and remodeled, affording a suitable place for the conduct of that part of the company's business and at the same time providing comfortable and convenient quarters for the men in the train service. One section of the carhouses formerly occupied by the old shop has been remodeled for this purpose.

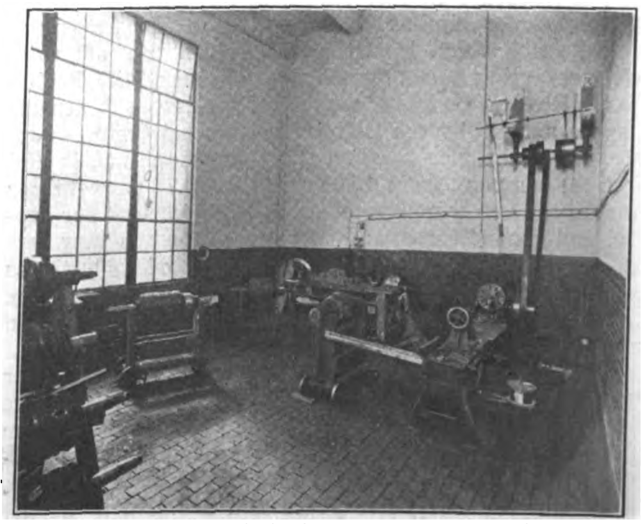
These quarters occupy ground-floor space, 20 ft. x 167 ft. in size, and a portion of a second floor, 20 ft. x 35 ft. in size. On the ground floor is situated the office of the station foreman and the cashier, and the trainmen's room, lavatory, assembly and instruction room. In the second story, which only partially covers the ground-floor rooms, are located the offices of the superintendent of transportation and a store room for stationery.

Concrete floors were provided throughout the trainmen's quarters and the walls are skirted by a 4-ft. wainscoting of pine-stained flemish oak, above which they are plastered with a hard plaster. The lavatory is equipped with every necessary toilet convenience.

Along one wall of the trainmen's room is a shelf for



DALLAS REPAIR SHOP—INTERIOR VIEW OF BLACKSMITH SHOP



DALLAS REPAIR SHOP—VIEW OF CORNER OF ARMATURE REPAIR ROOM writing purposes and above this is a succession of frames attached to the wall for holding the schedule sheets of the various lines. Long benches have also been provided, so that trainmen may sit at the shelf and copy their schedules, make out their trip sheets, etc. In order that the trainmen may have some form of amusement to occupy spare time while waiting to take out their runs, and that the club idea may be encouraged, the company has placed tables for checkers and dominoes in the train room. These games have proved to be popular with the men.

Adjoining the trainmen's room are the lavatory and toilets, and back of these is the general assembly room. This latter room is used for lectures, trainmen's meetings, the meetings of the safety league, and also by the trainmen's instructor for holding his classes in train operation. In this room has been installed a moving-picture machine, with which the company gives two shows each week for the benefit of the men and their families. The seating capacity of the assembly room is about 300, and the attendance at each picture show taxes the room to capacity. These shows are given free to the employees and afford them considerable pleasure. Occasion is taken at these entertainments to throw on the screen "safety first" mottoes and other instructions which may be apropos.

The general design of this new shop and transportation quarters follows the ideas of Richard Meriwether, general superintendent of the company, and John L. Brown, the master mechanic, while the Stone & Webster Engineering Corporation were the contractors and did the construction work. The development of the construction details and the supervision of the construction work were under the direction of T. L. Thornberg, engineer, and J. L. McCampbell, superintendent of the Dallas office of the Stone & Webster Engineering Corporation.

Rate of Return in California

The ELECTRIC RAILWAY JOURNAL of May 16, 1914, page 1075, contained an analysis of conditions under which public utilities in California are required to raise new capital, as presented by A. F. Hockenbeamer in the case of the Pacific Gas & Electric Company vs. the City and County of San Francisco before the United States District Court. An interesting commentary on Mr. Hockenbeamer's testimony appears in a recent decision of the California Railroad Commission in the case of the County of Antioch vs. the Pacific Gas & Electric Company, regarding rates for electrical energy. It is stated that the defence in this case filed an affidavit by Mr. Hockenbeamer similar to that used in the first-mentioned case, which is still pending. In this affidavit, after referring to the financial condition of the Pacific Gas & Electric Company and to certain issues of securities authorized by the California Railroad Commission, Mr. Hockenbeamer reached the conclusion that it had cost the company from 6.1 per cent to 10.75 per cent per annum to borrow money on security obligations for capital and expenditures, and that unless the company was able to derive profits from the operation of its business equivalent to at least 8½ per cent per year on the money invested or to be invested it would be unable to obtain capital necessary to carry on its business.

In commenting upon this statement, Commissioner Thelen assumes as a normal case that in order to secure each $100 to be invested the company secures $75 from the sale of bonds and $25 from the sale of stock. If the utility's bonds bear interest at the rate of 5 per cent, run for thirty-five years and are sold at 85 per cent of their face value, this being the condition obtaining with reference to the Pacific Gas & Electric Company's present general and refunding bonds, the company would be paying for this money, considering both interest and discount, at the rate of 6.1 per cent per annum. The $75 to be derived from the sale of bonds would accordingly cost the company each year $4.575. If a return of 8 per cent were allowed, this would leave a difference of $3.425 to pay dividends on stock and to yield a net profit in excess of interest and dividend requirements. This sum of $3.425 would yield interest at the rate of 13.7 per cent per year on the sum of $25 to be derived from the sale of stock. The commission states that no reasonable person will contend that it is necessary for a company such as the Pacific Gas & Electric Company to offer to its stockholders a rate of return of 13.7 per cent in order to induce them to supply the necessary funds in addition to those derived from the sale of bonds, and the conclusive answer to any such claim is the fact that the company is now selling to its stockholders at 82.5 preferred stock bearing interest at the rate of 6 per cent per annum. If an allowance of 8 per cent were made by the rate-fixing authority on money derived from the sale of stock, the sum of $2 would be necessary on each $25 derived from this source. By adding this sum to the $4.575 necessary for the bonds, the total cost of money derived from both bonds and stock would be $6.575, which falls short by $1.425 of the allowance made to the company if a return of 8 per cent were granted.

Commissioner Thelen then finds that a return amounting to 8 per cent of the fair and reasonable value of the property is at least a fair, reasonable and liberal return on the company's investment. He emphasizes the fact, however, that the commission in granting this return is allowing more than is necessary to secure all the company's capital from both stocks and bonds under proper financing and that the amounts so allowed in excess may well be said to be $1.425 on each $100 in value. The decision rendered is based on the assumption that the utility did not have bonds outstanding in excess of the value of the property but that there is a normal relationship between the face value of the bonds and the value of the property, and that the utility's funds have been secured in part from the sale of bonds and in part from the sale of stock. In reply to Mr. Hockenbeamer's statement that by a mortgage provision no additional bonds of the company can be issued until its net profits during a given period available for the payment of bond interest have been at least one and one-half times the amount of interest on all outstanding bonds, the commissioner states that one and one-half times the above mentioned $4.575 amounts to $6.865, which is still considerably below the sum of $8 allowed.

In regard to the fact that the Pacific Gas & Electric Company during the last year sold $7,000,000 of 6 per cent one-year gold notes on a 10.75 per cent basis, Commissioner Thelen says that this transaction cannot be considered a normal one. The price paid is the highest paid for money by any public utility on any authorization for an issue of securities made by the California Railroad Commission since the effective date of the public utilities act. The money was obtained at a time of recognized financial stringency and at a time when the company was spending millions in foundation expenses which could not be expected to yield a proper return for at least a number of years. The company was compelled to have this money in order to complete its construction work and the price paid cannot be controlling in establishing the proper rate of return.

The Society for Electrical Development, Inc., New York, N. Y., has issued a report to its members, which describes in an interesting way the manifold activities of the society in encouraging the progress of the electrical industry.

A Study of Insert Special Work Failures

Results of a Comprehensive Analysis of the Forms of Failures in Various Kinds of Insert Special Work Under Different Classes of Service

The article entitled "Chicago's Experience with Solid and Insert Manganese Special Track Work," published in the issue for May 2 of this paper, attracted a great deal of attention and showed the widespread interest in track work problems on electric railway systems. One of the conclusions derived from that article was that, as a rule, insert special work equaled, and in some instances surpassed the serviceability of solid manganese steel special track work. The quality of the steel in the insert, as compared with that in solid work, was considered at length, but no attempt was made to discuss the defects in the entire piece which develop under service, because that was considered to be a subject for special study.

In order to establish a premise for this study of insert special track work, it will be assumed that every defect which prevents a piece from wearing uniformly under traffic is a failure, regardless of the service the piece has rendered. Experience has shown that, although insert work in general is cheaper in first cost, it at least equals the serviceability of the more expensive types of frogs and crossings when installed under similar conditions. Despite this record, however, it is believed that some of these imperfections which hasten the wear-life limit may be eliminated, thereby making it possible to obtain a more uniform and a longer average life from this class of construction. Moreover, it is believed that the problem to be solved is not entirely one of manufacture but that the railways, in many instances, have attributed the causes of failures to material and workmanship when they should properly have been charged to poor choice of design, improper installation and lax maintenance. On the other hand, serious flaws have occurred in a number of pieces which are due to faulty design and manufacture. These usually occur early in the life of a layout, and generally they are directly responsible for other complications in the piece or its foundation.

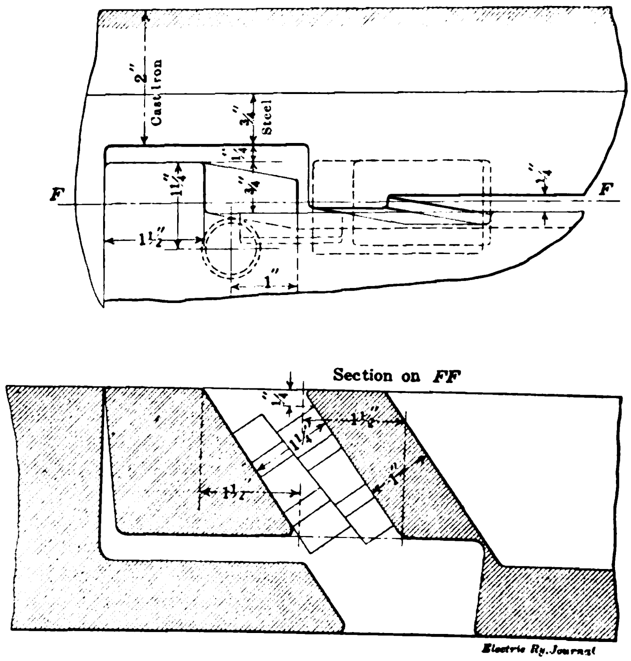
INSERT SPECIAL WORK—FIG. 1—INSERT WITH SPELTER BEARING AND PATENTED, BOLTED FASTENING

EXTENT OF INSPECTION

In order that this study might be comprehensive in character and convincing in results, an inspection trip was made over the principal properties in the Central West. These properties included the Illinois Traction System, the Michigan United Traction System and the railways in Milwaukee, Chicago, Detroit, Toledo, Cleveland, Columbus, Cincinnati, Indianapolis and St. Louis. In addition to this personal inspection, the benefit of the experience of engineers on other properties has been obtained through correspondence, and the plants of the principal manufacturers of street railway track special work have been visited. From the list of the properties visited it will be seen that all classes of traffic were included, from a simple street railway service, through a combination of street railway and interurban railway service, to that of the exclusively interurban railway. In addition to the various classes of service, considerable care was exercised to see that practically all types of track special work were inspected under the various conditions.



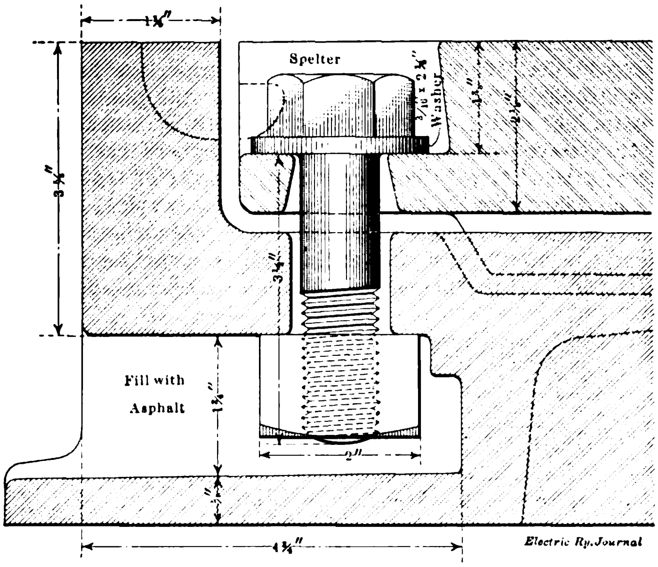
INSERT SPECIAL WORK—FIG. 2—INSERT WITH SPELTER BEARING AND WEDGED-IN FASTENING

TYPES OF INSERT SPECIAL WORK INSPECTED

All insert special work may be divided into three classes so far as the insert setting is concerned, namely, that which is supported entirely in a spelter bed, that which is partially supported on a machined bed and surrounded with spelter, and that which is provided with a completely machined bearing. Insert fastenings are essentially of two kinds, those which may be renewed from the pavement surface, and those which may be renewed only by removing portions of the paving on each side of the insert pockets. The latter type of fastening is manufactured in two designs, namely, the bolted-down and the keyed-down construction, in each of which the bolt or key serves to clamp the insert and the main casting together. The former is in three designs, namely, the keyed-in, the patented setscrew and the bolted-down fastenings. Both of the foregoing types depend on a wedging action between the insert and the main casting to hold the insert tight

Any of these types of fastenings may be had in cast-iron bound or in cast-steel arm construction.

Fig. 1 is an example of the insert supported wholly in a spelter bed and fastened so that it is renewable from the pavement surface. The durability of the fastening depends upon the pressure brought to bear between the insert and the edge of the pocket by the bolts and washers. In this type of construction the insert is made to fit fairly close where it joins the running rails, but no attempt is made to fit it along the sides of the pocket. After it has been set in its permanent position on shims, the interstices at the edges and beneath the insert are filled with spelter. Openings around the bolt heads are kept free of spelter and afterwards plugged with asphaltum to facilitate tightening in service.



INSERT SPECIAL WORK—FIG. 3—INSERT WITH SPELTER BEARING AND BOLTED-DOWN FASTENING TO SOLID CASTING

Fig. 2 is what is commonly known as the "wedged-in" insert fastening. This is also set and supported on spelter, but depends for permanence on a fastening obtained by two wedges which are inserted in each of four slots between the insert and the main casting. These wedges are tapered in opposite directions and bear against the main casting and the insert, which is forced down on the spelter bearing. In case it is desired to reset or renew the insert from the surface, this is accomplished by driving one of the wedges into the pocket, thus relieving the other. These wedges are not incased in the spelter in their permanent position but are sealed with asphaltum.

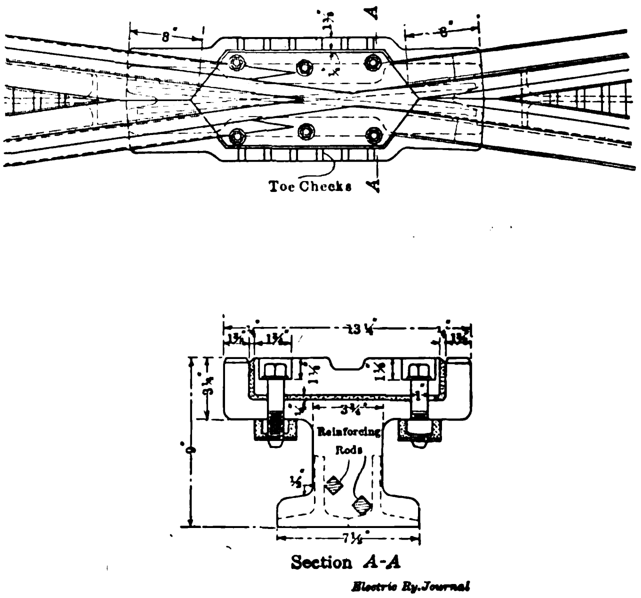
Electric Ry. Journal

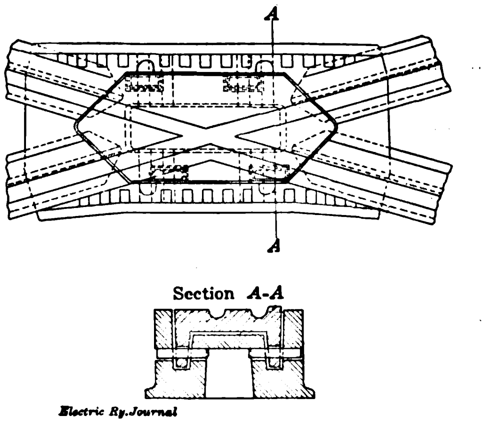
INSERT SPECIAL WORK—FIG. 5—INSERT WITH SPELTER BEARING AND KEYED-DOWN FASTENING TO CHANNEL CASTING

Another form of spelter-set insert is that shown in Figs. 3 and 4, commonly known as bolted-down construction. In the example shown in Fig. 3, pockets in the sides of the main castings are provided to receive the nuts for the bolts, which pass through the insert and the main casting into the pockets, where they engage the nuts and are screwed securely in position. After the insert is located in its permanent position on shims, the opening around the sides and that forming the bearing are filled with spelter. Following this operation the bolts are drawn up tight and their heads incased in spelter. To prevent the bolts from becoming loosened under vibration, the pockets containing the nuts are filled with asphaltum. As in the cases shown in Figs. 1 and 2, while the edges of the inserts adjoining the running rails are not made a machined fit, a neat fit is required at these points.



INSERT SPECIAL WORK—FIG. 4—INSERT WITH SPELTER BEARING AND BOLTED-DOWN FASTENING TO I-BEAM CASTING

Another form of insert fastening is shown in Fig. 5 and is known as the "keyed-down" type. After the insert has been set in its permanent position on strap liners, placed particularly at the points of impact, the spelter is poured in the remaining space to supplement the bearings on the liners. After the keys have been inserted to draw the insert plates down on the liners, they are again driven further to tighten the plate on



INSERT SPECIAL WORK—FIG. 6—INSERT SETTING AND FASTENING USED BY THE COLUMBUS RAILWAY & LIGHT COMPANY the combination liner and spelter bearing, after which spelter is poured around the lugs and keys to prevent the latter from backing. The lugs on the insert plate through which these keys are inserted project through the main casting below the insert, hence the wedges pull the insert down tight against the spelter bearing at the center. This type of fastening is not affected by the peening action of the insert, because any tendency to peen is resisted by the key fastening at the center. Openings on each side of the main casting permit these wedges to be driven or removed after a portion of the surrounding pavement has been removed.

Fig. 6 is another type of spelter-bedded insert of the keyed-down design somewhat like that shown in Fig. 5. This design originated with the roadway department of the Columbus (Ohio) Railway & Light Company. As shown in the illustration, it contains four lugs depending from the sides of the insert plate which fit into openings in the main casting. Each of these lugs is cast with an opening so that a key may be driven to fasten the insert down in its permanent position. The bearing on the main casting and the openings along the sides of pocket are sealed with spelter. In this design no special effort is made to obtain a tight fit between the plate and the running rails. It is claimed that this type of fastening retains the clamping principle of the bolted-down fastening while eliminating the possibility of stretched bolts.

Another type of insert setting and fastening is that known as the partially machined, supported design. Fig. 7 shows this type of construction used in conjunction with the ordinary bolted-down fastening. The plan sketch shows four circles located at points in the insert pocket at the ends of the rolled rail arms. These represent the machined bearing points or seats in the floor of the pocket and in the base of the insert. These machined spots are located so as to receive the impact blow of the wheel as it passes from the running rail to the insert. The opening at the sides of the insert and the remainder of the bearing are sealed with spelter.

Fig. 8 also represents this partially machined supported insert with the ordinary bolted-down fastening. Like the insert support shown in Fig. 7, machined seats are provided at the points where the insert plate receives the impact blow as the wheel passes from the running rails to the insert. In this construction a neat fit is made between the insert and the running rails, and the ends and other interstices are filled with spelter.

Fig. 9 shows still another form of a partially machined, supported insert of the bolted-down fastening type. In this design, however, the partial support takes the form of machined ribs in the floor of the pocket and in the base of the insert. The design provides for a neat fit at the points where the insert joins the running rails. The interstices in the bearing and around the edges of the insert are filled with spelter.

Fig. 10 represents the type in which the manganese insert rests on a fully machined seat, with a bolted-down fastening. In this class of construction, the floor of the pocket is carefully machined to provide a perfect bearing on the base of the insert, which is ground accurately to surface. The edges of the pocket, as well as the insert, are also carefully machined so that the insert fits tightly when set in its permanent position. This type of insert is usually employed with the cast-iron-bound construction with a minimum insert thickness of 1⅞ in., and the over-all thickness varying from 2¼ in. to 2⅜ in.

In Fig. 11 is illustrated a form of insert used principally in New England. It is cast-iron-bound construction with a forged steel insert which has been heat treated and set on a partially machined bearing. The sides of the insert are not machined to fit the pocket, but the ends of the insert and the pocket are accurately machined. The finished main casting is heated to expand the pocket when the cold insert is set in place. The shrinkage of the pocket is sufficient to hold the insert securely. Spelter is then poured along the edges of the insert and also fills the interstices between the rib seats. This type of construction has been quite successful under average city railway service; in fact, the forged steel insert wearing qualities compare very favorably with the average manganese-steel insert, and it does not chip.

Practically all types of insert fastenings and settings may be had in either cast-iron-bound or cast-steel-arm work. Considerable difference of opinion appears to exist, however, regarding the size and character of the cast-iron sections employed to bind the rolled rail arms in the cast-iron-bound work. The illustrations indicate that three designs are in common use, namely, the solid, the channel supported, and the I-beam supported castings. Some manufacturers are obtaining additional strength to resist transverse bending by increasing the sectional area, others by treating the cast iron to toughen it, and still others by reinforcing the cast iron with concrete reinforcing rods. Any one of these meth-

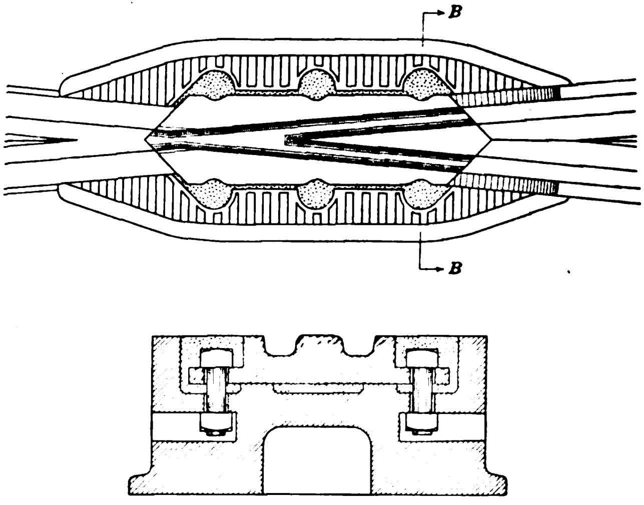
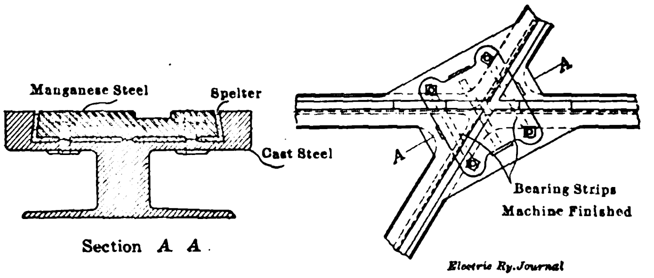
INSERT SPECIAL WORK—FIG. 7—INSERT WITH PARTIAL MACHINED BEARING AND BOLTED-DOWN FASTENING TO CHANNEL CASTING



Section B-B

Electric Ry. Journal

INSERT SPECIAL WORK—FIG. 8—INSERT WITH PARTIAL MACHINED BEARING AND BOLTED-DOWN FASTENING TO CHANNEL CASTING ods is good if the section is calculated for each class of service it is to perform; the only difference is that some insert supports weigh more than others. The cast-steel-arm work is also designed in various sections and depends on the heat treatment largely for its wearing qualities and strength. The remarkable development in the past few years in steel foundry practice has resulted in a marked improvement in cast-steel castings.



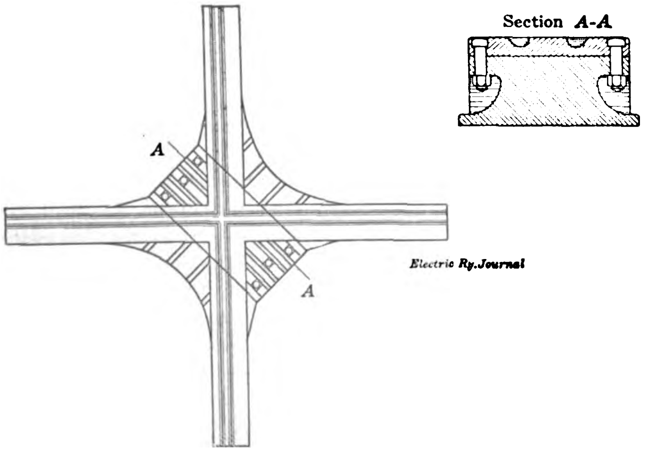
Electric Ry. Journal

INSERT SPECIAL WORK—FIG. 9—INSERT WITH MACHINED RIBBED BEARING AND BOLTED-DOWN FASTENING TO I-BEAM CASTING

CAUSES OF LOOSE INSERTS

Unquestionably the most common weakness of insert special work, under any class of service, is the loose insert. While the loose insert is responsible for many other complications in insert special work if not repaired promptly, other forms of imperfections arise from totally independent causes. Probably the form of failure second in importance is the loose arm in cast-iron-bound work. These loose arms are due either to breaks in the arms at the points where they set in the casting or to the loosening of the arms in the castings. The form of failure third in importance is the cupping in the rolled rail arm at the edge of the insert. Finally, a defect which is found principally where the traffic consists of heavy interurban cars is the broken casting.

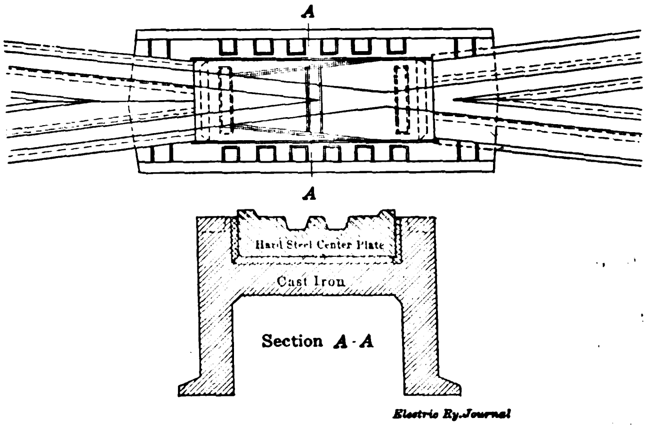
The maximum number of loose inserts occur in the spelter-bed setting. It is also found that certain types of fastenings give better results than others, but few pieces of this type appear to be able to meet modern heavy traffic conditions without becoming loose before the piece is worn out. Loose inserts are also found where the plate has a partially machined support, but as a rule these are not so numerous as in the spelter-bedded construction. In fact, in this class of special work it is believed that the manner of fastening has more to do with the loosening of the insert than the character of the support. Loose inserts are also found in work where the plate is wholly supported on a machined surface, but when they do occur the usual complications do not follow. The loose insert with this latter design, however, is an exception to the rule and in most instances may be attributed to the manner of fastening rather than to the type of bearing.



Electric Ry. Journal

INSERT SPECIAL WORK—FIG. 10—INSERT WITH MACHINED BEARING AND EDGES, AND BOLTED-DOWN FASTENING TO SOLID CASTING

Fundamentally the use of a spelter support under a manganese steel plate, purchased to furnish a material which would withstand the severest service conditions at the wear points, is wrong. Spelter may have a value in compression when confined, but this is comparatively small, and when the insert is subjected to severe impact blows there is a tendency for the manganese steel plate to tilt or flow after which the spelter cannot be expected to withstand the concentrated impact blows without compressing or flowing. It is believed that in many instances the insert becomes loose originally because the fastening does not hold securely. After the insert is once loose the spelter around the edges is sheared from that forming the bearing, and traffic soon jars it from its position beside the plate. When this spelter is gone, there being no bond between the spelter forming the bearing and the plate, it is but a short time until traffic vibration has loosened the insert fastening completely. If the insert is not reset promptly many other complications arise in close succession.



Electric Ry. Journal

INSERT SPECIAL WORK—FIG. 11—FORGED STEEL INSERT WITH PARTIAL MACHINED BEARING AND ENDS, AND SHRUNK-IN FASTENING

At best the only purpose of the spelter setting is to save machine work. While the design of most insert pockets in the body castings, either in the cast-iron-bound or cast-steel work, make it difficult to machine the edges or the bearings, it is not impossible to change the shape of the pocket so that it can be machined easily. Of course these difficulties in machining do not arise with the insert shapes except in some instances where they are complicated, and these could be obviated by the use of simpler shapes. Many of the manufacturers are now making the machined bearing insert special work either on specification or as their own standard. While those who have not made a regular business of manufacturing this class of construction claim that it is more expensive than the spelter-bedded pocket type, others state that when everything is equal they are in a position to meet the manufacturing cost of the other types.

The necessity for an all-machined bearing is questionable, and it is probable that a partially machined bearing sufficient to spread the impact load over a reasonable area of the casting will produce the same result. It is important, however, in any case to use a fastening that will not loosen under vibration or be subject to shear under side thrust when an insert becomes thin and peens under severe service. It is possible, of course, to reduce this peening to a minimum if the insert is thickened to a point where it is too rigid to assume a convex shape in the pocket, even up to the expiration of its wear-life. The location of the machined bearings is important and the bearings now in use are good, although it is doubtful whether sufficient area is used.

EFFECT OF STEEL WHEELS

While the use of miter joints between the insert and the running rails has materially aided in reducing the impact blow at this point, a machined fit also helps to reduce the number of loose inserts to a minimum, particularly in acute-angle crossings. In the obtuse and right-angle crossings, however, while the machined miter joint should be used to reduce the impact blow to a minimum at this point, it is very difficult to eliminate this blow at the intersecting flangeways. A number of engineers and manufacturers are attempting to accomplish this by using a flange-bearing insert throatway, but it is almost impossible to maintain it in a flange-bearing condition, owing to the rapid wearing away of metal under thin steel wheel flanges. A long, gentle approach from a non-flange bearing to a flange bearing, however, will materially aid in increasing the life of the metal in the throatway floor. When the approach is short, a slight blow is struck by the wheel flange as it comes in contact with the throatway, and, as a consequence, it is but a short time until the badly-worn flanges have cut their way through the flange-bearing insert plate. The gentle approach is obtained by the use of a large plate, or the cast-steel arm with the shallow throatway may be carried all the way through the piece, or the approach in a rolled rail groove may be built up with a welder.

Since rolled-steel wheels have come into common use in street and interurban railways, a new difficulty has developed in connection with track special work in paved streets. Worn steel wheels are believed to have added to the number of loose inserts. Thin flanges in combination with a canted truck cause one wheel to run flush against the flange while the other wheel on the same axle is pulled away from the gage line. In this position the latter wheel must either mount the insert plate, if the throatway is narrow, or it must strike a hard enough blow at the throatway entrance to right the truck. This difficulty is more or less obviated by providing a long, gradual approach from the running rail into the throatway in the insert plate. Unless this approach is gentle, a considerable blow will be struck on the plate as the wheel passes into or over it. This tends to loosen the insert and at the same time shear off the bolts or other fastenings. In many instances, derailments may be charged to the thin-flanged rolled-steel wheel rather than to any defect in the design of the insert throatway or to any variation in the track gage.

On streets where there is dense vehicular traffic, the heavily-loaded trucks undoubtedly contribute their share to the number of loose inserts as well as worn guards and running rails. Manufacturers usually exercise considerable care in providing a neat joint at the running rail connections to the insert plate to reduce impact but do not take such precaution at the sides of the plate, which are also subjected to impact blows from vehicular traffic. Attention in this direction no doubt would also be productive of improved results.

INSERT REPAIRS

Insert repairs and renewals are being made by the larger companies with more or less success. It may be stated, however, that during the life of the spelter-bedded inserts most companies expect approximately 80 per cent of them to become loose. This means that this percentage of inserts must be reset or renewed. This repair work should be done by a gang especially familiar with insert renewals and replacements. In fact, this gang should do nothing other than inspect work for defects and make the repairs. With the smaller companies it is practically impossible to retain these experts, but most of the manufacturers now have men whom they can send out to do such work, or at least supervise the repairs and replacements.

An inspection for loose inserts can be made to best advantage immediately after a shower. At this time, if the insert is slightly loose a car passing over it will cause the water or air bubbles to be forced up between the edges of a loose insert and the body casting. Many companies make it a practice to allow inserts to become quite loose before they attempt to make repairs. This practice probably renders easier the making of the insert repairs but unquestionably results in the extension of the effects of the loose insert to the rest of the track structure.

LOOSE ARMS IN CASTING

As mentioned earlier in this article, the second most common form of failure is the loose arm in the cast-iron-bound work. Most manufacturers have been able to overcome this difficulty by exercising care in preparing the rolled-rail section to receive the casting. Generally speaking, the rolled-rail arms are very carefully cleaned of scale and rust, after which they are painted with a fluxing material. In addition, most manufacturers are providing lugs or bolts in the rolled-rail web to anchor it in the casting. The shape and size of these lugs vary with the different manufacturers. It is also usual to drill a number of holes in the rolled-rail-arm web so that the cast metal may bond through these holes. In the past it was customary to punch these holes, but it was found that the metal surrounding the hole was checked and this tended to impair its strength. These holes are now drilled so that the metal surrounding them is left in good condition.

While a few isolated cases of loose rails in the castings may be attributed to the manufacturer, many of them are due to non-uniform bearing on the track foundation. The casting surrounding the insert may be high and the point of bearing at the end of the rail arm low, or the reverse may be true. In either case the casting forms a fulcrum, and the rail breaks or is loosened at the weakest point. In cases where the rail is broken the fault probably lies with the railway company, while in cases where the rail loosens in the casting the fault is entirely that of the manufacturer.

Probably there are a few instances where broken rails in the casting were due to partial annealing in the rolled-rail arm caused by the molten metal surrounding it in the mold. Then, too, the difference in shrinkage in the rolled rail and cast iron may have set up internal strains in the rail web which aided in rupture. Rolled rail shrinks about ¼ in. in 1 ft. from the molten to the solidified state, and cast iron shrinks approximately ⅛ in. in 1 ft. Since the cast iron does not shrink as much as the rolled rail, it is possible that the keying action of the head and the base of the rail against the cast iron during the period of solidification may set up strains along the web.

When the arm becomes completely loose, it is usually because there is not sufficient rolled rail area in the cast iron to hold it, under ordinary service. On the other hand, there are cases where the cast metal appears to shrink away from the rolled-rail arm, indicating that a fluxing material has not been used or that some action has taken place in the contact surface to prevent perfect bonding.

In many instances it is believed that a perfect casting with a good grip on the rolled-rail arm has been subjected to unnecessary strains because of lax track maintenance. Unquestionably the severe impact blows dealt at intersecting flangeways of obtuse angle crossings ultimately pound down the foundation beneath them. As a result of this, the portion of the casting immediately beneath the intersecting flangeway becomes a suspended point, and either the casting must break or the arm must loosen or break in the casting. It appears that the only solution for this difficulty is the proper selection of timbers and spacing to support the special work. These timbers must be of sufficient area to transmit the impact load stresses to the track foundation so as to reduce settlement to a minimum. It is also necessary to give the spacing of these timbers consideration so that it will be possible to tamp the track securely at the time it is laid, as this will enable the maintenance gang to retamp it to take care of unequal settlement. Ties of special lengths provide more uniform bearing than ties of standard lengths, because the latter must be interlaced so closely that there is no space left for tamping.

It is possible to eliminate some loose rails by increasing the grip area between the casting and the rolled-rail arm. Most manufacturers, however, now have enlarged the casting to a point where further increases would be uneconomical. On the other hand, if the track and roadway departments expect to lay down track special work and forget it, there is no limit to the size to which these castings must be increased to provide for this dilatory maintenance. It is more economical and better practice to devote closer attention to track maintenance, since an increase in the size of the casting means greater first cost as well as added cost for installation.

BROKEN CASTINGS

A form of failure which appears to be common to interurban railways is the broken casting. In many instances where the modern types of iron-bound insert work are used, the failure of castings may be charged to the railway company, and is probably due to unequal bearing and improper track maintenance. On the other hand, there have been cases where this type of failure may be attributed to the use of castings which are too small, or the point of impact is suspended between ties instead of supported on them. Some interurban railway companies are now using 7-in. girder grooved rail or T-rail in track special work where they should be using a 9-in. rail. This deeper rail would permit the manufacturer to provide castings of sufficient cross-section to withstand reasonable transverse bending stresses.

Another important factor in the failure of iron-bound castings is the choice and spacing of ties. If standard ties are used under a special-work layout, usually it is necessary to interlace them under the frogs, thus making it practically impossible to tamp that portion of the track foundation. Consequently settling occurs, requiring the casting to stand tensile strains in its base far beyond those considered in its design. If, therefore, a reasonable amount of metal is used in the binder casting, allowing a 9-in. instead of a 7-in. rail depth for heavy interurban traffic, and if special ties are employed to provide sufficient spread of the track loads on the foundation as well as to permit proper tamping, and if these are followed by careful and prompt maintenance, breaking of castings will be reduced to a minimum. Moreover, at the present time, failures of this description are not common to all interurban track special work nor to any one manufacturer's design.

UNCOMMON DEFECTS

Other forms of failures occurring in insert special work, important but unusual, include broken arms and cupping in the rolled-rail arms at the point where they join the insert plate. A break in the arm outside of the binder casting is due to the choice of rails with too high a carbon content. Broken rails in the casting, are due either to internal stresses resulting from the difference in shrinkage in the cast iron and the rolled rail, or to the partial annealing of the rolled-rail arm when it is surrounded with the molten cast iron. In any event, uneven bearing on the ties is the primary cause of rupture. In other words, internal strains or the improper annealing seldom sufficiently reduce the strength of the section to a point where it will fail under traffic alone.

In many instances what appears to be a loose arm in the casting will, upon examination, prove to be a break in the arm. Usually this break begins at the base of the rail near the edge of the casting and follows the line of weakest web section, namely, through the holes bored in it for anchor bolts or designed to allow the metal to bond through them, finally reaching a point immediately beneath the ball of the rail at the edge of the insert pocket. Breaks of this character are, as a rule, due to uneven foundations rather than to any cause which could be charged to workmanship or material.

Cupping in the rolled-rail arm at the edge of the insert pocket, is due, in most instances, to the use of too sharp a run-off from the flange-bearing insert to the non-flange-bearing rolled-rail arm. This allows the wheel to drop as it passes from the insert to the rolled rail, hence cupping develops at this point as quickly as it does at joints. On the other hand, there are cases where this cupping is due to the partial annealing of the rolled-rail arm. Cases have also been observed in which the pounding action has been so severe that the ball of the rail has actually been mashed down over the web, but these are exceptions to the rule. If a gentle flangeway approach is provided or if the flangeway in the rolled-rail arm is built up to meet the floor of the flangeway in the insert plate, defects of this character will be eliminated.

It is the intention in a later article in this paper to illustrate and discuss some typical examples of special work failures, as considered in this article.

Circular of Safety Rules

The bureau of standards of the Department of Commerce has recently issued circular No. 49 on safety rules to be observed in the operation and maintenance of electrical equipment and lines. The circular is in three parts, as follows: Part I—Rules for the employer; *a*, organization; *b*, protective methods and devices. Part II—General rules for the employee; *c*, general precautions; *d*, general operation; *e*, handling live equipment and lines; *f*, killing supply equipment and lines; *g*, killing moving parts; *h*, making protective grounds. Part III—Special rules for employees; *i*, power-station operation; *j*, switchboard operation; *k*, overhead line operation; *l*, arc lamp operation; *m*, underground operation; *n*, meter operation; *o*, testing operation; *p*, signal line operation; *q*, tunnel and subway operation.

The circular covers its subject in a most comprehensive manner. S. W. Stratton is director of the bureau of standards.

The *Electric Railway & Tramway Journal* is now the name of the English publication formerly known as the *Light Railway & Tramway Journal*. The change in name is significant as indicating the change from light steam and horse-operated narrow-gage lines to standard gage electric operation.

Export Conditions and the War

Data Showing Trade Prospects of London House of J. G. White & Company and also Export Situation in Brazil—Steam Railroad Moves to Increase Commerce—Experiences of B. J. Arnold in Europe

LONDON TRADE CONDITIONS

J. G. WHITE SAYS THAT THE TRADE OF HIS LONDON HOUSE HAS IMPROVED OVER THE SITUATION EXISTING JUST AFTER THE WAR BEGAN.

J. G. White, president J. G. White & Company, Inc., of New York, and chairman of J. G. White & Company, Ltd., of London, has consented to give his views of the trade conditions resulting from the European war to the ELECTRIC RAILWAY JOURNAL. In answer to an inquiry from a representative of this paper Mr. White explained that the London house conducts all of the business of the organization in South America and the Orient and, in fact, in all parts of the world excepting North America, Cuba, Central America and the Philippines. The business in North America is conducted by the New York company. The London house was established in 1900 and is connected with the New York organization through the fact that Mr. White, the active head of the New York company, is the largest stockholder in the English company. The business of the London house has recently been mainly in South American enterprises of the kind that have been financed principally in England.

Mr. White said that general business conditions, as far as the London house was concerned, have improved over the situation just after the beginning of the war. Necessarily the operations of the London house have been curtailed to some extent. Work on some of the enterprises in which it was engaged has been deferred until after the close of the war, but on others steady progress is still being made. Mr. White said that Great Britain has largely restored normal facilities for overseas shipments and that advices have been received from the London house that English manufacturers are prepared to make prompt deliveries of all of their usual products. The London house is prepared, notwithstanding the continuation of war, to procure and ship promptly, subject to government exemptions and restrictions, any materials or supplies that can be secured in Great Britain or any of the countries with which that nation now trades.

Regarding American business, Mr. White stated that financial conditions preceding the declaration of war were unfavorable to the undertaking of new enterprises, and that these conditions have been tremendously emphasized by the war, with the result that very little new engineering or construction work is proceeding. At the moment the most active part of the J. G. White Engineering Corporation is understood to be its purchasing department. Recently important purchasing commissions have been received from Porto Rico, Cuba, the Philippines and other parts of the world. This department undertakes commissions to purchase in America any kind of machinery, materials or supplies for clients in the United States or, in fact, in any part of the world. It does not attempt to secure orders which otherwise might go to its allied London company or others in Great Britain, realizing that it is of primary importance for the best interests of the world that the industrial population there should be kept employed as far as is possible. On the other hand, the department takes orders from any part of the world for any purchases, whether emergency or usual, which existing world conditions make it advisable to procure in the United States.

BION J. ARNOLD IN THE WAR ZONE

MR. ARNOLD RETURNS AFTER HAVING WITNESSED THREE ARMY MOBILIZATIONS—SOME OF HIS OBSERVATIONS ARE GIVEN BELOW.

Bion J. Arnold, chairman Board of Supervising Engineers, Chicago Traction, accompanied by Mrs. Arnold, returned from Europe on the *Campania* on Saturday, Sept. 12, after having had the remarkable experience of witnessing the mobilization of the armies of three countries within as many weeks. While awaiting the attention of the customs officers on the Cunard line pier, Mr. and Mrs. Arnold gave to a representative of the ELECTRIC RAILWAY JOURNAL a graphic picture of recent conditions in France, Belgium and the British Isles.

Mr. Arnold went to Europe about the middle of July as a member of the Chicago railway terminal commission, which is organized under the authority of the City Council of Chicago for the purpose of studying the important questions relating to railroad terminals in that city and recommending general policies and plans for the future development of these terminals. This study includes also the subject of docks and harbors as, on account of the location of Chicago, shipping and railroad terminals problems are closely related. The commission included, beside Mr. Arnold, John F. Wallace, chairman, Walter L. Fisher, Edward H. Bennett, Lawrence E. McGann, John W. Beckwith and Ellis Geiger. The commission was accompanied on the trip by a party of fourteen associates representing various civic interests.

The purpose of the European trip was to secure data from the experience of other countries in the problems connected with water and railroad terminals, especially as regards the relations of transportation interests to local interests and plans. The original itinerary included Liverpool, Manchester, London, Paris, Frankfurt, Vienna, Dresden, Berlin, Hamburg, Kiel, Copenhagen and Stockholm, with the possible addition of Budapest and Leipzig. As a result of the declaration of war while the party was in Paris, it was decided to postpone visiting Germany and to go to Brussels and Antwerp instead. The war developed so rapidly that the party returned to England Aug. 2 and disbanded in London on Aug. 3. Most of the members promptly returned as best they could, and Chairman Wallace and Mrs. Wallace sailed on Aug. 15. Mr. Arnold stayed until Sept. 5 in order to continue his investigations and to extend them into the electric traction field. As the readers of the ELECTRIC RAILWAY JOURNAL will be interested particularly in Mr. Arnold's experiences and observations, attention will be directed to these rather than to the interrupted work of the commission.

Mr. Arnold's first intimation of the impending international difficulties was received at a gathering at the American embassy in Paris held in honor of the visiting commission. Here Ambassador Herrick, who has since acquitted himself so creditably, announced the receipt of a telegram stating that Austria had declared war on Servia, which he feared and felt meant a general European war. The effect on the party, which was attended by leading officials of the French government, was most depressing, and it soon broke up in gloom. The visitors realized at once that the mission could go no further, and the retreat began. The members of the Chicago party, however, resolved to make the most of the opportunity by visiting in neutral Belgium and proceeded to Brussels after having witnessed the preliminary movements of the mobilization of the French army. On the evening of the arrival of the party in Antwerp they witnessed the reading of the mobilization order for the Belgium army and later saw the soldiers start for the front. Before learning that Germany had declared war on Russia the party left for England just in the nick of time, for two days later Liége was besieged and the invasion of Belgium begun. They arrived in England the day before England declared war on Germany and in time to witness a third army mobilization which was continued throughout Scotland and Wales.

Being in close touch with officials high in authority in the different countries, Mr. and Mrs. Arnold secured an unusually accurate picture of conditions. They agree that the stagnation of business in the important cities is complete, the endeavors of merchants and manufacturers being directed to conserving their stocks and capital until times improve.

In England and Scotland Mr. Arnold enjoyed excellent opportunities for his investigations. In addition to the terminal question he especially studied motor buses, underground rapid transit facilities and electrolysis, all of which are important matters in connection with present Chicago conditions. He found that there is no general complaint of electrolytic corrosion, as the Board of Trade rules are quite generally complied with and seem to be effective under traction conditions in England. This matter is of particular interest to Mr. Arnold at present as he is chairman of the joint national committee on electrolysis. In fact, he called a meeting of the committee for last Monday in New York by cable before sailing. In addition to the cities already mentioned Mr. Arnold visited Glasgow, Edinburgh, Newcastle, Leeds and Manchester, as well as several points in Wales.

He was much interested in the plans used in replacing the car crews lost temporarily through the war. Service had been furnished without serious interruption. Travel is, of course, much lighter than normal on account of the business depression.

RAILROADS AND SOUTH AMERICAN TRADE

A pamphlet has just been issued by the Lehigh Valley Railroad with a view to presenting to American manufacturers information on the subject of trade possibilities in South America. In condensed form the bulletin gives for ready reference statistics showing the volume of business in each commodity and the division of that business between the United States and Europe. It is stated that the names of South American firms engaged in the importing business are on file at the company's office and will be furnished on application. The pamphlet discusses in general the available and prospective banking facilities in South America, the effect of the Panama Canal, trade conditions, rules for procedure in reaching buyers and other points concerning all the countries. In connection with each a brief explanation is offered of the currency, weights and measures and postal systems used. An appendix contains a digest of steamship facilities, postal regulations and latest estimated population of South American cities.

Another interesting feature adopted by the Lehigh Valley Railroad is its "South American Special," which is to stop at the principal cities on its line and acquaint manufacturers with the details of the South American market. In addition to detailed information regarding the kind of products, the tariffs of the various countries and items of a similar nature, it is understood that the train will carry financial and commercial experts, who will be able to give the manufacturers first-hand information. As planned, the "South American Special" will stop at Easton, Allentown, Bethlehem, Scranton, Wilkes-Barre, Elmira, Ithaca, Geneva, Auburn, Rochester and Buffalo. At each of the cities conferences will be held with the Chamber of Commerce relative to trade prospects.

The New York Central Lines and the American Express Company have also taken steps to help along the movement for the development of closer trade relations between the United States and South American countries. It is reported that the companies, acting jointly, have arranged to send to South America James Thane and A. B. Howard, as special representatives. Mr. Thane will represent both companies, while Mr. Howard will act as the representative of the financial department of the American Express Company. They will visit the chief commercial centers of Brazil, Argentina, Uruguay, Chile and Peru and obtain information as to the best and quickest means of transportation, the markets for American goods and the kind of goods desired.

COMMERCIAL CONDITIONS IN BRAZIL

According to Consul General J. G. Lay at Rio de Janeiro, the economic prosperity enjoyed in Brazil during the last four years has been temporarily checked. Since September, 1913, the country has been suffering from a financial, industrial and commercial crisis which has completely paralyzed the import trade. The federal government with reduced revenues has been obliged to defer payment for supplies and contract work amounting to $25,000,000. The business outlook is not encouraging, and unless money becomes available in Europe within the next few months there will be a heavy fall in exchange in Brazil.

About 75 per cent of the imports in Brazil comes from the United States, Great Britain, Germany, France and Argentina. The relative position of each country in percentage of total importations during 1912 and 1913 was as follows: United States, 1912, 15.6 per cent, 1913, 15.7 per cent; Great Britain, 1912, 25.2 per cent, 1913, 24.5 per cent; Germany, 1912, 17.2 per cent, 1913, 17.5 per cent; France, 1912, 9 per cent, 1913, 9.8 per cent; Argentina, 1912, 7.5 per cent, 1913, 7.4 per cent. The important electrical articles imported into Brazil during 1912 and 1913 and the principal countries of origin are shown by the accompanying table.

TABLE SHOWING ELECTRICAL ARTICLES IMPORTED TO BRAZIL AND PRINCIPAL COUNTRIES OF ORIGIN FOR 1912 AND 1913

	1912	1913
Cable:		
Total	$579,885	$822,870
United States	250,047	162,317
Great Britain	241,369	408,002
Germany	49,997	166,578
Insulators:		
Total	$204,388	$198,059
Germany	125,502	103,972
United States	55,044	63,718
Machinery:		
Total	$4,811,052	$3,347,249
United States	2,060,944	1,595,849
Germany	1,375,764	788,725
Great Britain	569,562	674,399
France	537,636	126,512
Electric motors:		
Total	....	$597,428
United States	....	214,614
Germany	....	168,095
Great Britain	....	94,365
Switzerland	....	57,986
Rails, fishplates and other railway accessories:		
Total	$9,384,650	$11,230,845
France	2,071,438	3,672,825
Belgium	3,318,764	2,786,429
Germany	1,344,151	2,019,087
United States	1,868,840	1,957,579
Great Britain	751,474	718,431
Wire, copper:		
Total	$1,293,638	$166,390
United States	851,550	33,935
Germany	285,042	84,064
Great Britain	65,115	25,082

American Association News

Section Activity Begins in Newark—The Meeting of the National Joint Committee on Electrolysis Is Held—College Men Are Planning to Get Together—The Manufacturers' Association Is Growing

PUBLIC SERVICE SECTION MEETING

The first meeting of the A. E. R. A. section of the Public Service Railway for the season was held at Newark on Sept. 17 with a very large attendance, including a considerable delegation from the Brooklyn Rapid Transit Company. A paper was presented by H. D. Briggs, assistant claim agent, on "Reducing Accidents." After calling attention to the large aggregate sum spent as a direct result of accidents by a company the size of the Public Service Railway, he emphasized the point by stating the annual cost of these accidents in terms of fares, interest on the company's capital, etc. He then pointed out that while there are certain necessary operating expenses which cannot be reduced much this is not true with regard to the accident account. Mr. Briggs urged persistence in safety campaigns, stating that, while many of these are effective, the interest dies out after a time and they lose their force.

One of the most interesting parts of his paper dealt with the standardization of parts of car equipment affecting public safety, such as steps, grab handles, doors, etc. He showed that many accidents are due to surprises to passengers in these lines. He also described the work of the Public Service Railway safety committee, which is composed of the general claim agent, the assistant general manager, the general superintendent, the mechanical engineer and the engineer of maintenance of way. Statistical reports of accidents and their causes have proved to be very useful to this committee.

Mr. Briggs was followed by W. G. Gove, superintendent of equipment Brooklyn Rapid Transit Company, who described in detail the Brooklyn center-entrance car. Mr. Gove explained the conditions which led up to the design of this car and gave an outline of the organization of the advisory council through which the president of the company keeps in touch with the requirements of the several departments. This organization, the center-entrance car and the safety movement are all closely related. The objects in view in the design of the new car were reduction of weight, large seating capacity and maximum possible length. By pushing all of these factors to the limit it was found possible to design a car which reduced the weight per seated passenger by nearly 40 per cent. At the same time the accidents, especially boarding and alighting, have been materially reduced. The design of the present car, of which 101 were constructed, began with studies made in 1910 and incorporates the ideas collected by the engineer of car equipment during an extensive tour made in 1912. While the construction of the car is familiar to readers of the ELECTRIC RAILWAY JOURNAL it may be interesting to note that the steel frame, which is riveted together, was built by an outside contractor but the rest of the work was done in the company's shops. The large seating capacity is not only obtained by means of large size but every possible nook and corner is utilized for seats.

In the discussion of Mr. Briggs' paper representatives of different departments of the company contributed valuable suggestions. W. B. Graham, of the Essex division, explained the results which had been secured by enforcing rigid discipline, rear-end collisions having been largely eliminated. One of the main difficulties in operating a railway is the violation of minor rules, and such violations must be promptly reported if discipline is to be maintained.

E. A. Palmer, central division, stated that the cost of accidents goes much further than the direct payments to injured persons, for equipment must be repaired. The Public Service Railway treats its employees so well that the company should have the co-operation of every employee in keeping down accidents.

Howard McSherry, attorney of the claim department, pointed out how this safety movement is getting down to first principles. He made an interesting observation as to the variation in degrees of carelessness in different parts of the country, pointing out one or more where people seemed to be unusually oblivious to their own safety. He aroused some amusement by pointing out the effect of present styles of women's dress on the safety movement.

C. H. Coe, chief instructor, explained how the "following up" movement in the instruction of motormen tends to reduce accidents. It is difficult to put brains into men, but good discipline with careful following up will accomplish wonders.

After the papers and discussion, A. J. Van Brunt, of the claims department, exhibited several safety moving-picture films which have just been completed. One of these was released this week by the Edison company for exhibition throughout the country. The name of the Public Service Railway appears on the screen announcements between scenes so that the company will get a wide publicity in its safety movement. The new films are the result of co-operation between the film manufacturers and the company, by which more economical results are possible than by any other plan so far used. A series of scenes in "The Life of a Motorman" are of particular interest, combining romance, business and safety propaganda in a unique manner. After witnessing the considerable number of thrilling accidents staged on real track and with real cars and familiar scenes the Public Service Railway section has a new stimulus to reduce the number of accidents.

JOINT NATIONAL COMMITTEE ON ELECTROLYSIS

A meeting of the joint committee was held at the American Electric Railway Association offices on Sept. 14. The meeting was called by cable from England by Chairman Arnold for the purpose of learning early in the season of the progress which had been made by the sub-committees appointed last spring. The make-up of these committees was given in the issue of the ELECTRIC RAILWAY JOURNAL for April 4, page 763. The progress of the work of the committees was informally discussed and another meeting was appointed for Nov. 12. At this date it is expected that the general committee will elaborate its plans. Those in attendance at the meeting were B. J. Arnold, representing American Institute of Electrical Engineers, chairman; E. B. Rosa, national bureau of standards, secretary; W. J. Broder, Natural Gas Association of America; A. S. Richey, Calvert Townley, American Electric Railway Association; E. B. Katté, American Railway Engineering Association; Philip Torchio, L. L. Elden, National Electric Light Association; A. P. Boeri, E. Miller, American Telephone & Telegraph Company; A. F. Ganz, J. A. Gould, American Gas Institute.

CORNELL A. E. R. A. REUNION

Cornell University men who expect to attend the Atlantic City convention are requested to send their names at once to H. H. Norris, ELECTRIC RAILWAY JOURNAL, 239 West Thirty-ninth Street, New York. A reunion similar to that held last year is being planned. Last year there were fifty Cornell men on the Pier, and one-half of these were able to get together for lunch. There was some complaint from the younger men that the lunch was unnecessarily expensive and this year arrangements will be made for a much less costly lunch. If men of other colleges want to get together and will send their names to Mr. Norris he will be pleased to put the men of each institution in touch with each other. A considerable number of college teachers are expected and it will be a fine chance for a reunion.

COMMITTEE ON LIFE OF RAILWAY PHYSICAL PROPERTY

The joint committee on the life of railway physical property held a meeting at the association headquarters in New York on Sept. 12. The committee went over the draft of the report for the Atlantic City convention and completed the work. The following were present: Robert N. Wallis, Fitchburg, Mass., and Martin Schreiber, Newark, N. J., co-chairmen; Edwin Gruhl, New York; William H. Forse, Jr., Anderson, Ind., and Robert B. Rifenberick, Detroit, Mich.

MANUFACTURERS' ASSOCIATION

The following new members have been secured to the Manufacturers' Association: Seymour Portable Rail Grinder, Waltham, Mass.; Lutz-Webster Engineering Company, Philadelphia, Pa.; Wasson Engineering & Supply Company, Milwaukee, Wis.; Grayson Railway & Supply Company, St. Louis, Mo.; Electric Car Waste Company, Philadelphia, Pa.; Burdett-Rowntree Manufacturing Company, Chicago, Ill.; Harrison Safety Boiler Works, Philadelphia, Pa.; James L. Howard & Company, Hartford, Conn.; Hauck Manufacturing Company, Brooklyn, N. Y.; Sauvage-Ward Brake Company, Inc., New York, N. Y.; American Creosoting Company, New York, N. Y.

Committee on Trade Expansion

Secretary of Commerce Redfield on Sept. 15 named the following men to act with a committee of the National Foreign Trade Council in working out plans to expand trade with Latin America: William A. Gaston, Boston, banker; Harry A. Wheeler, Chicago, banker; Alba B. Johnson, president Baldwin Locomotive Works, Philadelphia; Robert Dollar, San Francisco; John Barrett, director general Pan-American Union; W. D. Simmons, St. Louis; Fairfax Harrison, president Southern Railway; Lewis W. Parker, Greenville, S. C.; W. B. Campbell, Cincinnati, and Dr. Clarence W. Owens, of the Southern Commercial Congress. The committee of the National Foreign Trade Council, of which James A. Farrell is chairman, has been at work for several weeks with the Latin-American Consular delegation in New York. The entire committee now will confer with the diplomatic corps from South America.

Some of the material and equipment installed in the power plant of the Forest City Railway, the old 3-cent line in Cleveland fathered by the late Tom L. Johnson, is being used by the Fort Wayne Engineering Company, Fort Wayne, Ind., in the buildings which it is constructing in Fort Wayne for the Fort Wayne Rolling Mills. After the settlement in Cleveland the plant of the Forest City Railway was sold.

Dr. Rosa on Electrolysis

Dr. E. B. Rosa, chief physicist of the bureau of standards, Department of Commerce, Washington, D. C., addressed the New England Waterworks Association upon electrolysis at its convention in Boston, Mass., on Sept. 10. For about four years the bureau has been studying this subject and the results of its researches have been published in its technological papers. In his paper, Dr. Rosa outlined the investigations already completed and pointed out the interest of the bureau in seeking to remedy local conditions in conjunction with electric railway companies, municipalities, water companies and other owners of underground metallic structures. A résumé of the address follows:

The effect of electrolysis upon reinforced concrete has been investigated by the bureau, the results being printed in Technological Paper No. 18, a document of 136 pages, which contains an extended study of the destruction of the bond between reinforcing bars and concrete by electrical action. Technological Paper No. 25 deals with the electrolytic corrosion of iron in soils. This form of corrosion and self-corrosion, due to chemical action of soils, are mutually interactive. The efficiency of corrosion varies greatly in different soils and in different cities, striking differences being noted in the bureau's researches in St. Louis and Philadelphia. Soil resistance varies greatly with temperature, and electrolytic action is so much less in cold weather that electrolytic surveys should preferably be made during the warm season. A range of from 400 to 1800 ohms per centimeter cube was found between St. Louis and Philadelphia soil resistances. A discussion of the methods of making electrolytic investigations will shortly be published as Technological Paper No. 26.

Dr. Rosa said that the surface insulation of pipes as a preventive of electrolysis appears to be ineffective where the voltage conditions are severe, as the coatings tend to become weak in spots and to intensify the corrosion through localization. The bureau has tested a great number of paints, dipping compounds and wrappings for pipe service, and has reached the conclusion that these are of little value in positive areas near power stations. The tendency of such materials is to absorb moisture, with resultant formation of rust spots, gassing and ultimate rupture. Coverings are helpful in protecting pipes from self-corrosion where the current is negligible. Technological Paper No. 15 discusses surface insulation. Bitumastic enamel has not yet been tested by the bureau, but soon will be given a trial. Insulating joints in pipes are useful in reducing current flow, but where the potential gradient is high the joints must be spaced fairly close together. This method is economical and mechanically practicable as an auxiliary means of protection, and is specially useful in gas piping.

Of the two principal methods of electrolysis mitigation, carrying the current back to the station by conductors, or the so-called "track drainage system," is preferable to permitting current to flow into pipes and cable sheathing and then tapping from these to the station negative bus. The second method is generally used, but the bureau considers it complex, expensive and not easily maintained. The use of negative cables is simpler, more effective and far less expensive than is generally supposed. The second, or "pipe drainage system," is one which greatly increases the flow of current in pipes and cable sheaths, and often requires the use of jumpers around the joints of gas pipes. It is difficult to adjust the drainage effect and electrolysis is liable to result. The economy secured in power consumption and the improvement gained in voltage regulation, with its effects on car speed and car lighting, will often yield a fair return on the cost of an insulated return system, in the opinion of the bureau. At St. Louis, Mo., the adoption of insulated return feeders in place of pipe drainage cut the flow of current in the pipes from 844 to 85 amp. The investigation is fully described in Technological Paper No. 32. At Springfield, Ohio, insulated pressure wires have been installed in addition to the insulated negative cables, and the American Railways Company has decided to standardize this practice on its properties as a result, in part at least, of the work of the bureau.

CO-OPERATION BETWEEN BUREAU, COMPANIES AND CITIES

Dr. Rosa set forth the desire of the bureau to be of the utmost scientific service in the solution of electrolysis problems and said that it enters such cases, not as an advocate of any interested party but in a thoroughly impartial manner. There is room for much broader co-operation between all parties interested. At Los Angeles an engineer of the bureau investigated the electrolysis situation and secured the consent of the various parties to an unbiased investigation. Two electric railways and the water supply interests joined in the study instead of going to court as originally planned, and a comprehensive solution was developed. Dr. Rosa emphasized the importance of making adequate investigation before passing ordinances bearing on the electrolysis situation. In one instance it was found that by the installation of a moderate amount of negative copper, by the building of one new substation and the enlargement of another, the power distribution on the system was greatly improved and the territory safeguarded effectively against electrolytic troubles. Uniform requirements in this field established by law are undesirable, but a general law fixing responsibility is thoroughly defensible. The records of the bureau in these investigations are available to interested parties even before publication. At first the expense of the investigations was mainly borne by the bureau's appropriation from Congress, but as the work has expanded and the need of a campaign of education has become apparent, the larger portion of the cost has lately been borne by the water and railway companies. It is better to employ engineers to solve local electrolysis problem than to spend the money upon lawyers and experts retained to fix the responsibility for conditions without a constructive plan for their alleviation or rehabilitation.

DISCUSSION

Answering inquiries, Dr. Rosa said that a soil containing chemicals or the installation of pipes in cinder beds may result in self-corrosion as harmful as any that can be caused by electrolysis. Soluble salts and water are the principal factors in reducing soil resistance. The bureau favors the grounding of transformer secondaries as a safeguard to users of electric light and power in case of lightning trouble or a cross between the high and low tension windings. No danger from electrolysis should be apprehended in the practice of grounding secondaries. The bureau is most desirous of securing actual measurements of ground resistance, not only on transformer pipe and plate grounds, but also on lightning conductors. A direct current which frequently reverses is less effective in producing electrolysis than a continuous current. Concrete surrounding a pipe in earth will not protect it from electrolytic corrosion, but will protect it reasonably well against self-corrosion. A considerable current and comparatively high potential difference are required to produce electrolytic action where metal is imbedded in concrete. The elevated railways in New York no longer use the steel structure as a negative return.

COMMUNICATION

Municipal Ownership and Congress

THE BUREAU OF PUBLIC SERVICE ECONOMICS
NEW YORK, Sept. 11, 1914.

To the Editors:

Municipal ownership has again assumed national importance by the reporting to Congress of the bill for government purchase and operation of the street railways in Washington. The pending congressional election affords an opportunity to public utility representatives throughout the country to state their case fully and frankly to the men who will constitute the next Congress. It is a duty which the public utilities owe to themselves as well as to their associates, to take advantage of this opportunity. When they are seeking votes, candidates for Congress usually are glad to listen to their constituents. The public utilities in each congressional district from Maine to California and from Texas to Minnesota should arrange to present to the candidates of both parties, in definite and concise form, the facts about municipal ownership in general, the Washington situation and the bearing of the latter on local conditions. If the facts regarding municipal ownership were known by the representatives of the public the numbers of its adherents would wane. Now is a good time to get a hearing from the members of the next Congress. Public utilities should make the most of the opportunity. WILLIAM D. KERR, Director.

Valuation of Kansas City Light Company

In a case before the Public Service Commission of Missouri an interesting report was recently presented by P. J. Kealy, special representative in charge of appraisal, for the valuation of the Kansas City Electric Light Company and subsidiaries as of Feb. 1, 1914. The report is based upon an investigation of the cost of reproducing all the physical property actually in use on Feb. 1, 1914, and its depreciated value; of the investment and plant account, the gross and net return thereon; actual investment in superseded property and credits to plant account because of supersession, and of the complete history of the corporate, financial and physical development of the companies. Two bases of valuation were used: the cost of reproduction and the actual investment and net earnings thereon. In determining the first, the report places the cost to reproduce the physical property at $7,265,272, the cost of attaching business at $1,056,738, and the plant development expenses at $525,913, or a total of $8,847,922.

In determining the investment in the property the appraisers ascertained the actual investment year by year and added to or deducted therefrom the sum representing the surplus above or deficit below a fixed return made on this investment by the net returns from operations after payment of all ordinary expenses, including taxes, renewals and depreciation. The cost new of existing property was determined as $7,471,130 and the accrued loss thereon $1,851,491, or a total of $9,322,621. The return used in computing the above was 8 per cent. Taking into consideration the two valuations stated, the appraisers determined the fair market value of the Kansas City Electric Light Company and its subsidiaries as $9,000,000, exclusive of franchise value. It is stated that the franchise of the company is of great value, but necessarily conjectural, because the future rates to be paid have not been fixed and the value cannot be correctly estimated as in the case where an electric railway franchise authorizes the collection of a fixed fare.

Equipment and Its Maintenance

Short Descriptions of Labor, Mechanical and Electrical
Practices in Every Department of Electric Railroading

Centers—Fastenings, Renewability, Shape and Groove

BY R. P. WILLIAMS, INSPECTOR OF SPECIAL WORK BROOKLYN RAPID TRANSIT SYSTEM

In Brooklyn we have in use eight babbitted fastenings. Fig. 1 shows the horizontal key applied to a 90-deg. crossing. This fastening is very effective when applied to the Harveyized steel center, as then it does not have to overcome the effect of cold rolling. When manganese is used the condition under which the force of the keys is directed down and inward tends to bow the center, pulling the ends away from and loosening up the keys.

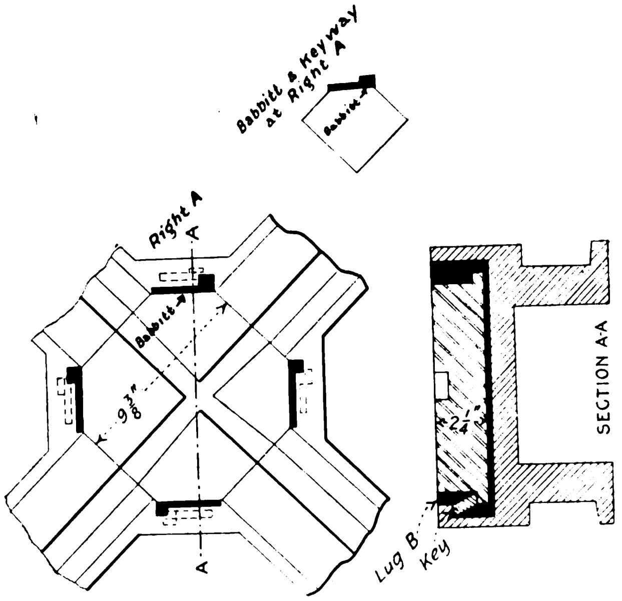

FIG. 1—HORIZONTAL KEY APPLIED TO A 90-DEG. BABBITTED CROSSING

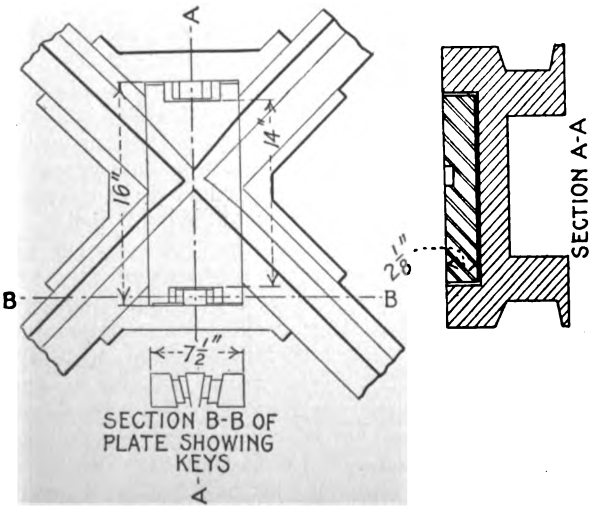

FIG. 3—VERTICAL KEY IN A 90-DEG. CROSSING

Fig. 2 shows the same style of key employed with the long narrow center in 90-deg. crossings. This is the fastening used in the crossing previously mentioned by the writer to illustrate the difference between hard and soft centers under traffic, and proves again that this fastening is not good for hard and soft steel. The other objections to this style of fastening are, first, the danger of breaking the retaining lug *B*, as shown in the sectional view of Fig. 1, and, second the great amount of babbitt chipping required to remove the center when it is used in branch-off frogs. The center is reversed in the latter case, the longer sides being used to key and generally having four keys to a side. Fig. 3 shows the vertical key. The remarks on Fig. 2 also apply to this center, except that it is easier to remove in branch-off frogs because of less chipping.

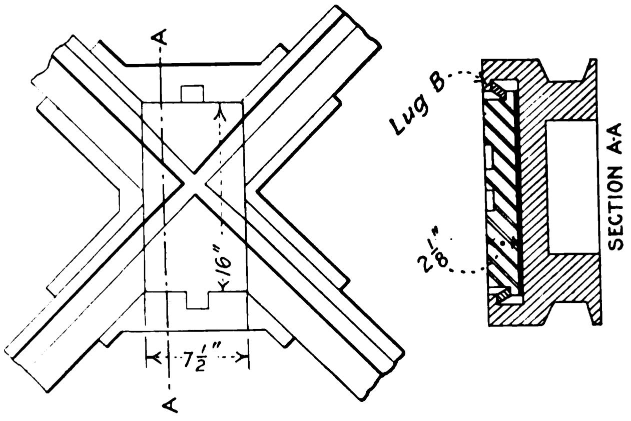

FIG. 2—HORIZONTAL KEY APPLIED TO LONG, NARROW CENTER OF 90-DEG. CROSSING

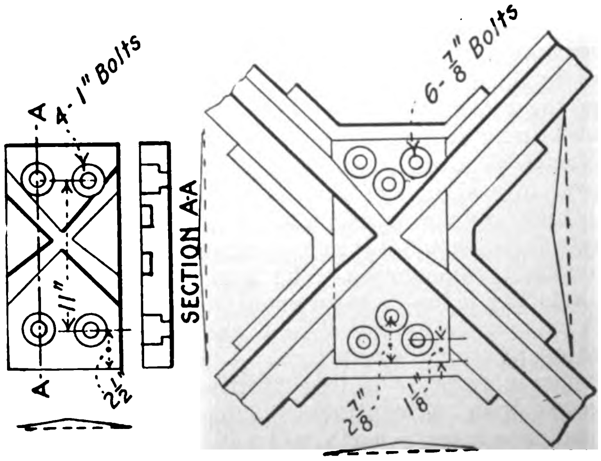
Turning now to the bolted fastenings and referring to the diagram at the bottom and side of Fig. 4, we will note particularly the action of cold rolling, as shown in full lines. Although all-manganese, the construction shown in Fig. 4 seldom loosens, while the fastenings of Fig. 5 rarely remain tight. The loosening action in Fig. 5 always begins with the two center bolts, which fact proves the necessity of equal downward pressure to resist cold rolling. For nearly three years we have been replacing the bolts of Fig. 5, in case of break, with open-



FIGS. 4 AND 5—TYPES OF BOLTED FASTENINGS

hearth steel. None of the new bolts have loosened up. In renewals of both of these types and in 25 per cent of the repairs the pavement must be removed.

Fig. 6 shows a type of center with bolts in compression. This type of fastening is effective in branch-off frogs or long centers, but great difficulty is experienced in 90-deg. crossings as they loosen very easily under the effect of cold rolling.

Fig. 7 shows the pendant lug. This is the most effective fastening now on the market to resist cold rolling, since, from its nature, it must become tight as the metal flows on the wearing surface. Its only fault is the difficulty, if not impossibility, of renewing the center without removing the piece. Fig. 8 shows a bolted center (patent applied for) which we are giving a thorough test, especially in 90-deg. crossings. The aim in this case has been to develop a center from which all of the objectionable features previously mentioned have been removed and all the good qualities retained. Time and car wheels will show if we have attained this end. So far the results are very good.

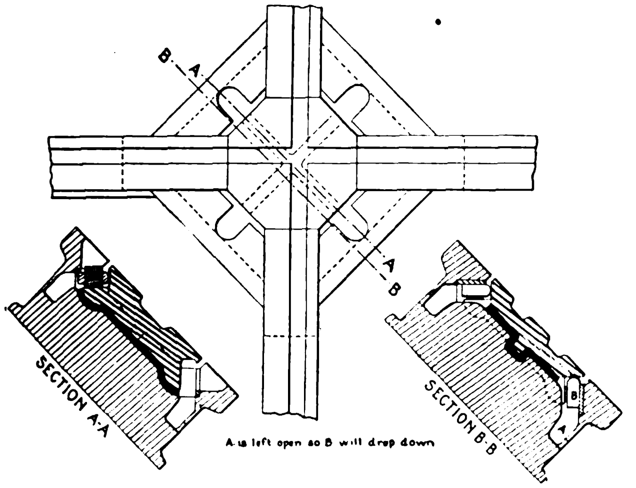


FIG. 6.—TYPE OF CENTER WITH BOLTS IN COMPRESSION

As to renewability: If you are the manufacturer of special work and can offer the consumer, under guarantee, "a center which will stay tight until it has reached a condition where repairs are made necessary, by a reasonable amount of traffic, at which time it may be removed without disturbing pavement, in a quick, safe and economical manner," you may safely count on receiving the order, for the only guarantee of getting the full value out of special work is to keep the intersections in serviceable condition. This can be done only by having the renewable features in the center. In case of noise complaint what is to be done where the renewable feature is not used? Grind the centers? If this is done the center, instead of increasing the life of the special work will diminish it. The late test of manganese in Chicago would have shown different results had a renewable center been used because a larger percentage of good inserts of manganese can be made than of large castings. Unless the intersection in manganese can be maintained the loss is proportionately greater than the same failures in ordinary insert work.

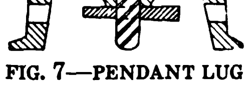

FIG. 7—PENDANT LUG

The material used in the center and the manner of fastening must be considered in determining its shape. Where steel, in which cold rolling takes place, is used, the fastening must be such as to give an equal downward pressure. This end cannot be attained in the long, narrow center so much used in 90-deg. crossings. As a result, instead of securing any benefit from the miter effect at the connecting edges of the insert and the abutting rail, the opposite is the case because when cold rolling raises the insert in the middle or loosens it, an unequal wear is set up between the hard and soft metals. The results are the breaking out of the rail ends which abut the hard center and the destruction of the crossing.

Groove width and depth have received too little attention from the user and the maker. No rigid rules can be laid down as to depth, but the tapers in floor levels and approaches could be uniform. In 90-deg. crossings, for instance, if ⅝-in. is given for floor level, the only portion of the groove floor left at that level should be the square of the narrowest part of the groove. The taper should end so as to deliver the wheel to the center, not to the abutting rail, while the portion remaining could be ground to the practical depth required in the field. The width of groove in all centers should be as small in the narrowest or crossing portion as the wheel flange will permit without binding or lifting the wheels.

It may be added that we are now trying treated centers and bolts of the "Mayari" type in three installations, one branch-off and two crossings.

If this matter of detail were drawn as fine as possible the results would more than justify the necessity for extra care.

The Return Circuit—Bonding Precautions

BY HOWARD H. GEORGE, ASSISTANT ENGINEER MAINTENANCE OF WAY, PUBLIC SERVICE RAILWAY, NEWARK, N. J.

Many faulty bond installations have been made, and the value of the bond as a conductor has been greatly impaired, due either to ignorance or to lack of attention to details on the part of the bonder. To reduce this trouble the following code of instructions, issued on one railway to aid those in charge of rail bonding, may prove of value to others.

1"
SECTION A-A

FIG. 8—NEW FORM OF BOLTED CENTER NOW ON TRIAL

1. Every roadmaster and foreman should see that one or more men in each gang are taught the proper way of installing bonds, and should be sure that any bonding done thereafter is performed by these men.

2. When renewing rail or joint plates on single track in operation, care should be taken not to open or disconnect both rails at the same time, as this would open the return circuit by which the current returns from the cars to the power house. When it is absolutely

necessary to open both rails, a long copper jumper should be installed to connect the open ends so that the path of the return circuit shall not be interrupted. This applies more particularly to road ends and interurban lines.

3. Whenever any track is opened up and any ground wires for electric lights, lightning arrestors, or other electrical apparatus which should be connected to the rail, are found disconnected, they should be reported at once to the bond inspector or distribution department, so that they may be repaired before the track is closed up. This is very important and should receive careful attention.

4. No bond holes should be drilled until just before the bonds are ready to be put in. There are, of course, times when it is desirous to have the holes drilled before the rail is placed on the ties. When this occurs, it is necessary to place a tight-fitting plug in the hole as soon as it is drilled to avoid any possible introduction of moisture. To drill a hole a day or two before and not protect it from moisture means a film of rust in the hole, which will greatly increase the resistance of the joint. (An accompanying cut shows the machine used by the Public Service Railway for drilling bond holes.)

5. Old bonds should never be used again because they become battered up in driving them out. Then, when they are put in again they will not make good contact with the rail, which means a poor bond. Where a bond is removed from the rail it is not advisable to use the same hole in putting in a new bond, unless some precautionary methods are used. The proper way is to drill a new hole, but as this is not allowable in some types of rails ream out the old hole and use a bond with a special large-sized terminal.

RETURN CIRCUITS—MACHINE USED FOR DRILLING BOND HOLES

6. Great care should be taken with the drills used in making bond holes. If an improperly ground drill is used the hole will be irregular and oval shaped, thus giving a poor contact between the terminal and the rail. All dull and broken drills should be carefully boxed, labeled and sent to the shop to be reground, where the company has installed a special machine for the purpose to do the work perfectly and at much less expense than could possibly be done by hand.

7. In drilling bond holes never use oil to lubricate the drills. It is better not to use anything, but where it is absolutely necessary to use a lubricant, nothing more than a soda solution should be employed.

8. Holes, after being drilled, should be carefully cleaned of any chips, and wiped dry of any solution that may have been used to lubricate the drills. The holes must have a smooth and dry surface so that the bond terminal will make a good contact all around.

9. With a proper-sized hole, the bond terminal will make a very snug fit, not small enough to have to be driven with a heavy maul nor large enough to be put in easily with the hands. It should require a couple of taps with a hammer weighing about 3 lb. With a heavy hammer or spike maul, the head of the bond terminal is very liable to be battered, and the taper punch struck on the slant, causing it to split and bend the terminal.

10. After the bond terminals are in position, always drive the long steel taper punch entirely through the terminal, taking care to strike the punch squarely on the head. The small end of this punch should be dipped in some kind of heavy grease, such as track grease, just before it is driven through each terminal. The grease will lubricate the sides of the punch, thereby expanding the terminals and not drawing the copper with the punch.

11. Drive into each of the expanded terminals one of the short drift pins, thus expanding the copper a little more. This pin should be driven in until it is just flush with the head of the bond terminal.

12. The bond should then be shaped by straightening out the bond conductors, and forming them so that they will not be cut by either the track bolts or the splice bars. If it is a 36-in. bond, it should be so shaped that it will in no way interfere with the removal of the splice bars.

13. The bond, and particularly the bond terminals on both sides of the rail, are to be painted with some good weatherproof paint, care being taken to see that the paint fills the space back of the terminal heads.

Overhead Problems—Catenary Construction—III

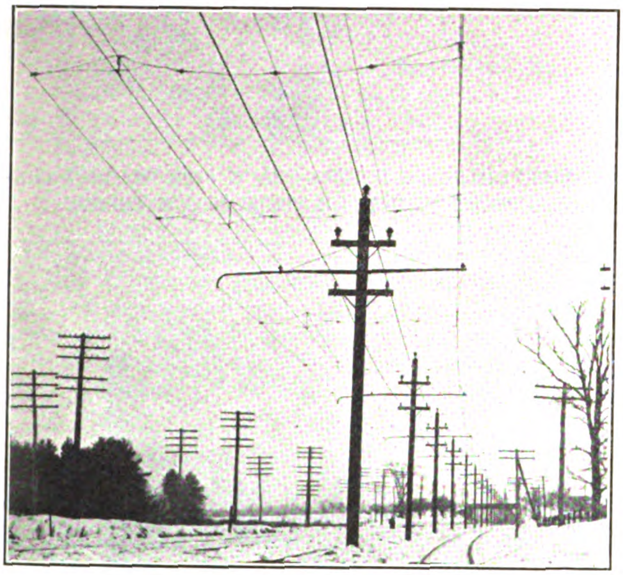
BY CHARLES RUFUS HARTE, CONSTRUCTION ENGINEER CONNECTICUT COMPANY

The different viewpoints of American and foreign engineers are again seen in the treatment of contact wire alignment; abroad the line is zigzagged from side to side, usually about 1 ft. each way, to distribute the wear over the top of the shoe; here, the line is almost always centered, as it is found that the natural side sway of the pantograph is ample to give all necessary side travel. Indeed even with center location it is essential that track and overhead departments maintain close co-operation lest a change in superelevation without a corresponding line shift results in the shoe being thrown entirely clear of the contact wire because of unavoidable side play.

The fear of fouling has been more in the hearts of our own designers than abroad. At turnouts the diverging wire is by all lifted above the level of that of the main line, but for pantograph operation early American catenaries used a gridiron of wires to fill in the space between to a point where the end of the shoe could by no chance go over the branch wire. Later designs follow the foreign practice of merely raising the branch wire, which, however, is rigidly held to that elevation throughout the fouling space by special double hangers.

Curve dressing is complicated, particularly on flexible, simple catenary. To prevent tipping there must be two attachments; if made to the hanger rod the friction on the messenger absorbs much of the flexibility; if one attachment is made to the hanger rod or contact wire and the other to the messenger the pull-together effect of paired strands is equally undesirable. The best solution is the use of a spreader which keeps the two parts parallel for at least 6 ft. or 8 ft. from the catenary, beyond which they come together in a common pull-off. On rigid hanger lines this is unnecessary and the strands are attached to the messenger and to the bottom of the hanger rod or to an attachment to the contact wire which, for pantograph work, is sufficiently offset to prevent fouling. Sharp curves with several pulls per span employ either a bridle between supports to which the pulls are run radially, or else the pulls are run to the supports in fans; light curves either use the bridle or fan methods, or on heavy construction use a special pull-off pole. On light work flat curves offer so little side pull that the weight of the strands and insulator causes heavy sag; in one instance this was partly obviated by using a light single strand, which a short distance from the catenary was divided into two groups or three wires each, the seventh being served on to prevent further unlaying. One group of three wires was then taken to the messenger, the other to the trolley while the insulator was cut in at the bridle. It is, however, always desirable to have the like portion of pulls and the like as short as possible.

Foreign lines and a few American employ the rigid. steady brace attached to the main support, and rarely to a pole specially set for it. The elimination of special pull-off poles is secured, and the disadvantage of the line loading by the steady brace is obviated by extending the bracket to form a hook to which a pull-off strand is attached. In case the pole is on the outside of the curve the attachment is made directly to it.

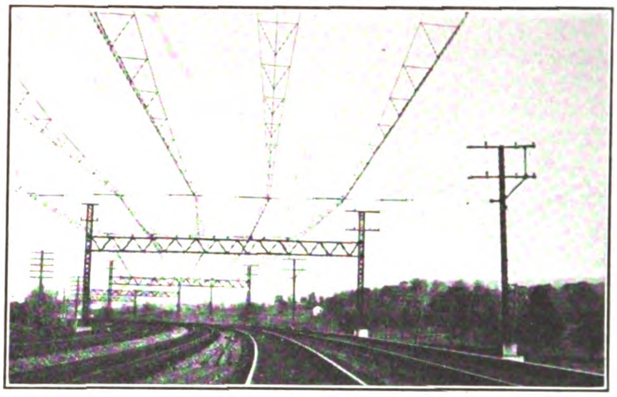


Note bent end bracket for pull-over.

CATENARY CONSTRUCTION—BRACKET SUPPORT, SARATOGA-BALLSTON SPA LINE, SHOWING DOUBLE-TRACK CENTER-POLE CONSTRUCTION

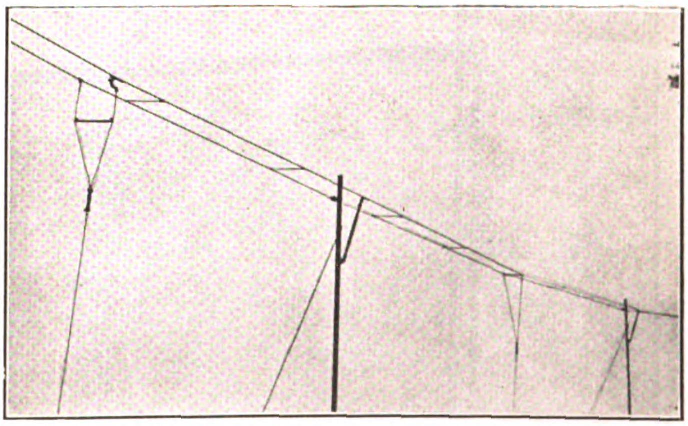
The use of cross-bents on the Harlem Branch electrification of the New Haven permitted the use of a bridle tied to these bents, pulling them partly to the desired offset from the chord of the messenger, a further shift of the insulators on the cross-bents bringing the contact wire over the track center. The most admirable device, however, is the Murray curve hanger, the head of which firmly grips the messenger holding the shank at an angle of approximately 45 deg. from the vertical while the lower end is a duplex clip, which is vertical. The lengths are such that the clips are true to line, making the chords but 10 ft., while the inclined shank permits the contact wire to yield to the pressure of the shoe against the torsion of the messenger and the pull of the contact wire. In connection with shortened support spacing to keep the hanger lengths within reasonable limits this scheme, employed on the recent New Haven work and to be used on the Pennsylvania, gives an almost perfectly true alignment.

Figures of cost, particularly of the heavier installations, do not abound. W. J. Wilgus has stated "on good authority" that the first New Haven electrification cost in excess of $50,000 per four-track mile. Whatever the cost, it could be duplicated at materially less, as much of the material had to be specially developed; for example, W. S. Murray mentions (*Transactions American Institute of Electrical Engineers*, Vol. XXX, page 1424) that strain insulators originally cost $61 each against $7 two or three years later for a device much better both mechanically and electrically. Figures for the latest work on this road have not been made public, but it is a safe guess that there has been a reduction of at least 30 per cent in the cost, and probably nearer 50 per cent. The entirely different labor and material conditions abroad demand extensive corrections to make the costs of foreign installations comparable to American work. The Siemens-Schuckert installation on the Seebach-Wettingen experimental line, with wood-pole support, is said to have cost $4,000 per single-track mile; the Hamburg-Altona, with steel bridges, is credited with $5,400 for the same unit; while the Rotterdam-Hague-Scheveningen, with steel bridges and messengers broken at each span, is reported as costing $5,900.



Compare this result with that shown in the view of the Murray curve hangers in preceding article

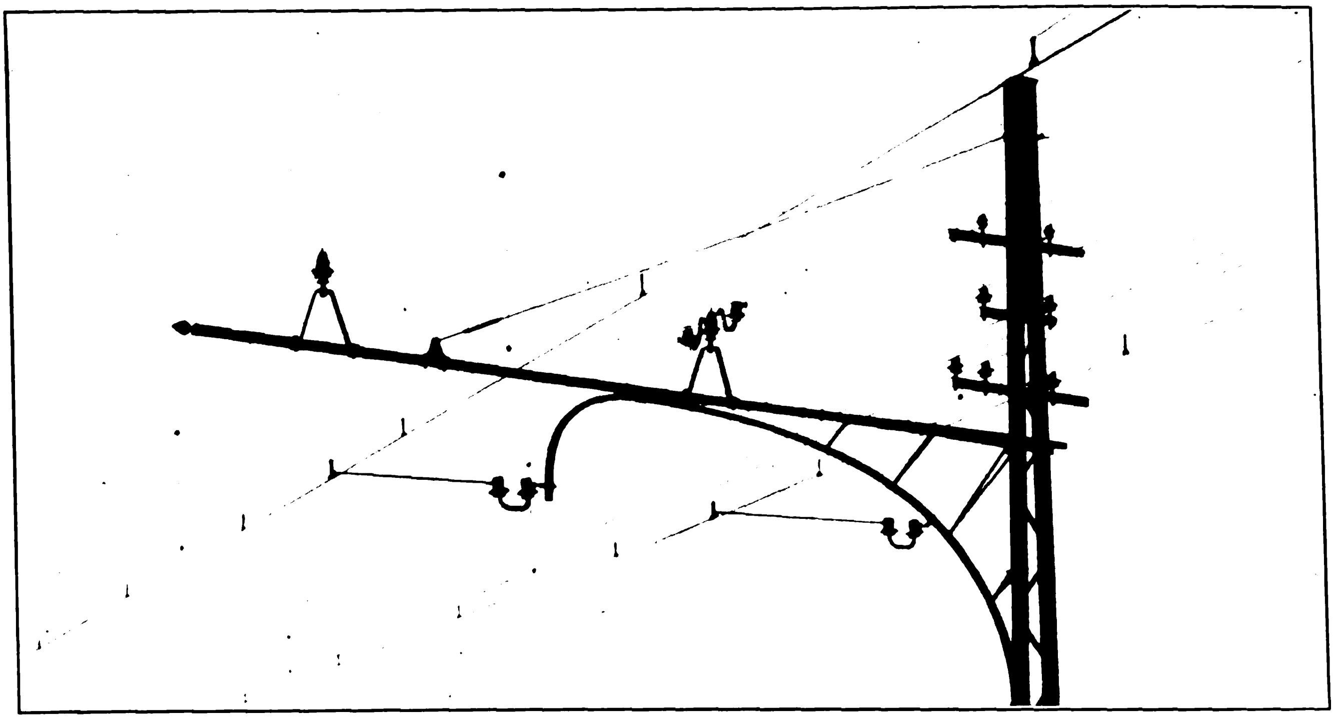
CATENARY CONSTRUCTION—CURVE DRESSING, SHOWING PULL-OVER ON THE PIONEER NEW HAVEN INSTALLATION



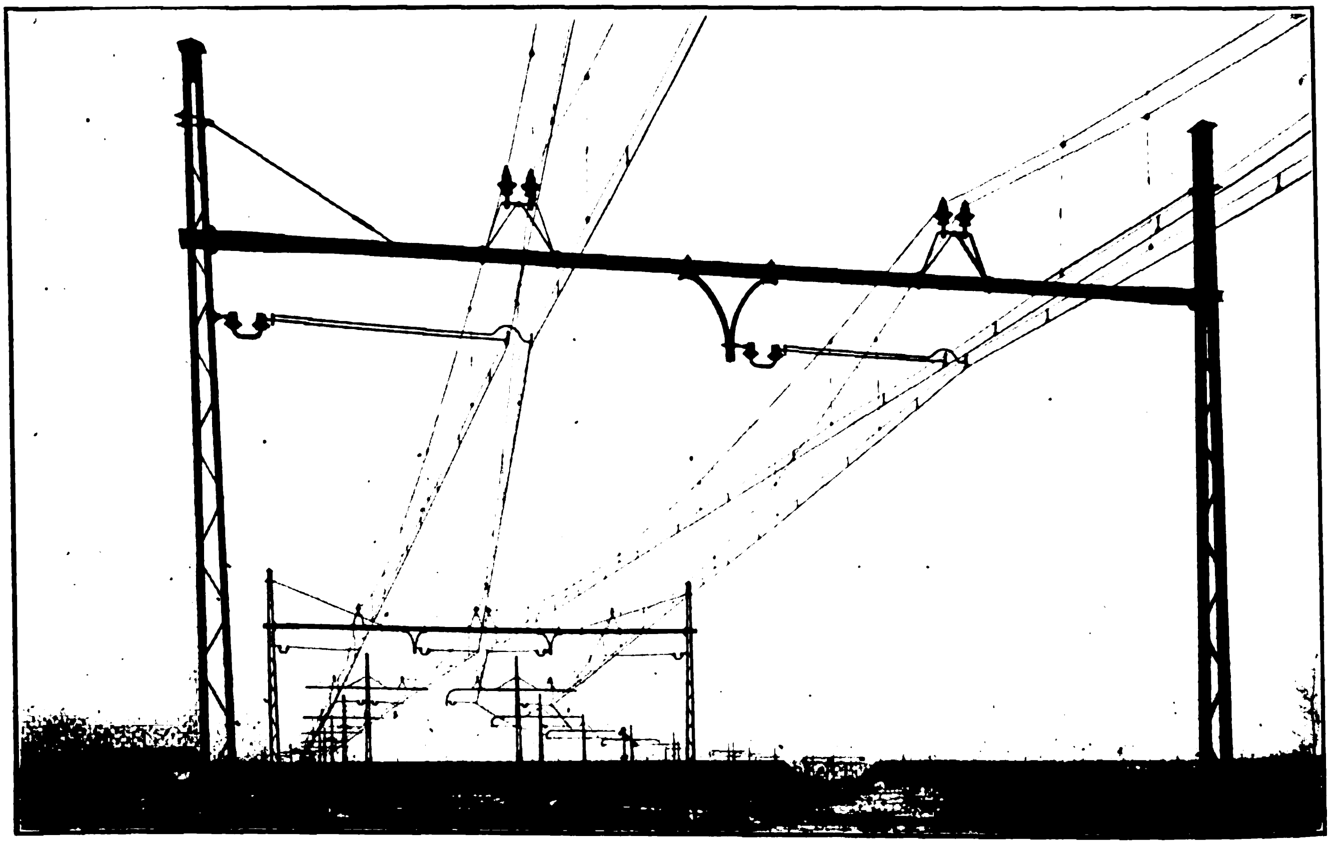
CATENARY CONSTRUCTION—FORM OF CURVE DRESSING, SHOWING PULL-OVER WITH SPREADER TO PREVENT PINCHING

Of the lighter types the Archbold-Brady construction on the Syracuse, Lake Shore & Northern cost $4,100 per double-track mile as against $3,325 for the standard wood-pole simple suspension, on which latter, however, the poles were on unusually short spacings.

On the Rochester, Syracuse & Eastern the 500,000 circ.-mil copper feeder cables were made to do duty as messengers as well, reducing the cost to $3,425, or but $100 more per double-track mile than for the customary forms of wooden pole construction.



CATENARY CONSTRUCTION—BRACKET SUPPORT BLANKANESE-HAMBURG-OHLSDORF DOUBLE-TRACK SIDE BRACKET CONSTRUCTION. NOTE THAT ONE MESSENGER IS CUT AT EACH SUPPORT WHILE THE OTHER IS CONTINUOUS



CATENARY CONSTRUCTION—LIGHT BRIDGE ROTTERDAM-HAGUE LINE, SHOWING STEADY BRACES IN FOREGROUND, AND CURVED END BRACKETS FOR PULLING TO LINE IN BACKGROUND

In considering the costs of installations it is of the utmost importance that all the facts be known. Differences in labor and material costs have very appreciable influence upon the final figures, but more than anything else are the conditions under which the work was done; the electrification of a line carrying traffic will take from two to four times as long, with corresponding higher cost, than if operation has not begun.

While experience has cleared up many until recently doubtful points there remain as yet unanswered two of particular importance in the case of heavy installations:

"What will occur when a serious track wreck involves the overhead?" That the troubles once feared from stray current are largely imaginary has been at least partially proved by wrecks on both third-rail and overhead systems; whether if on the latter one or more bridges are wrecked the catenary will constitute an added mechanical hazard is not yet clear, but the little evidence available indicates the probability that with one bridge partially wrecked the overhead will not seriously foul the unaffected tracks, and that such fouling as occurs can be readily cleared, while the probability of serious injury to move more than one bridge now seems quite remote.

The other question is: "What will be the effect of corrosion and other elements of depreciation?" While an authoritative answer as yet cannot be made as to the physical facts, it can be said that the roads that can finance a heavy electrification can and will give the installation such care in maintenance as to insure perfect safety of operation.

New Haven Construction Notes—Installing Hangers or Clipping-In

BY A FORMER INSPECTOR

The installation of hangers, called "clipping-in" by the erecting forces of the New York, New Haven & Hartford Railroad, was carried out on the main line with a work train composed of tower cars and tool cars. The trolley wires were hung to the ⅝-in. steel messenger with temporary hangers so that the wires would be in their approximate position and so that the ⅝-in. steel messenger would have its approximate load when raised.

The raising was accomplished by "Crosbying" to the ⅞-in. steel catenary cable a strap which had an eye for the attachment of a number of turnbuckles in series. These turnbuckles were either opened or closed all the way according to whether the ⅝-in. steel messenger was to be let out or taken in. A section of the construction train was sent ahead for this purpose so that the men on the clipping-in section lost very little time. The advance section was also provided with a dynamometer to pull the trolley wire to the proper tension. The hangers and intermediate clips were installed from the top of the tower cars which extended from one I-beam bent to the next. The hanger spacing was 10 ft. and the bent spacing 150 ft., plus or minus.

Fifteen men were employed on the tower cars from which the hangers and intermediate clips were installed, while two men were used to distribute the hangers. The inspector or foreman who measured the spacing for the hangers used a tape which extended from bent to bent, the hanger location being marked by him on the ⅝-in. steel messenger. The clips which joined the steel trolley or contact wire to the copper conductor were installed half way between the hangers. It may be added that the hangers came in standard sets and each was numbered according to the position where it was to be placed. One of the views shows one of the small tower cars in use for the installation of section insulators.

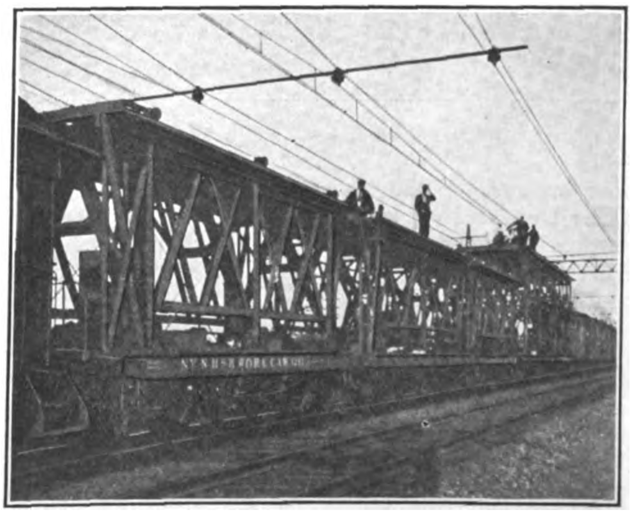
SMALL TOWER CAR FOR SECTION INSULATORS

TOP OF TOWER CAR WITH MEN CUTTING-IN TROLLEY SLEEVES

All of the work hereinbefore described was carried out under E. R. Gorman general foreman of the construction forces. Mr. Gorman had one of the best body of linemen with whom the writer was ever associated.

Reverser Handle Used as Key to Hand-Throw Signal Boxes

The Rhode Island Company, Providence, R. I., has developed a device which prevents the public from tampering with the hand-thrown signals used on its single-track city lines and which also forces the motorman to use his reverser to operate the signal, so that power cannot be applied when he is off the car. To make this possible, the company replaced the old knife switches in the signal boxes with snap switches. The ordinary rubber buttons were removed from these switches and a round piece of metal having a square hole in one end was substituted therefor. The switch is so mounted that the square hole is a fraction of an inch above an opening in the bottom of the box. Through this hole the motorman can insert his reverser, the end of which has been squared for use as a key. A twist of the wrist will throw the switch and operate the lights. While the motormen had always been ordered to remove the reverse handle on leaving the car, the new way is even more efficient as it makes unauthorized manipulation of both car and signal impossible.



CLIPPING-IN TRAIN WITH ONE TOWER CAR UP WITH TEMPORARILY-CLIPPED LINE AND COMPLETED LINE

Fifty Quadruple Traction Equipments for Providence Railways

Recently the Rhode Island Company, Providence, R. I., contracted with the General Electric Company for 200 type GE-200 motors, or fifty quadruple motor equipments, air-brake equipments and accessories to be installed on new, double-track cars which will be built for that company. The selection of this type of equipment was determined after a series of long-continued service tests of motors suitable for the operating conditions, made on the Broad Street line by the railway company.

The type GE-200 railway motor belongs to the line of newly designed standard motors of the General Electric Company. Under the A. I. E. E. standard, this motor has an hourly rating of 40 hp at 600 volts and 33 hp at 500 volts, but has a much greater service capacity than other designs of motors with the same hourly rating both for city and interurban service on account of its positive system of self-ventilation. The motors to be installed on these cars will be GE-200, Form E, of the box-frame type. They will be fully ventilated, are provided with commutating poles, and will be fitted with sixty-six-tooth, solid carbon steel gears and fifteen-tooth pinions.

The controllers to be installed on the cars will be double end type K-35-S-2, which are of the standard platform type manufactured by the company. Straight air-brake equipments will be employed with type CP-27 compressors. This compressor has a piston displacement of 15 cu. ft. of free air per minute when operating at 600 volts against a reservoir pressure of 90 lb. per square inch.

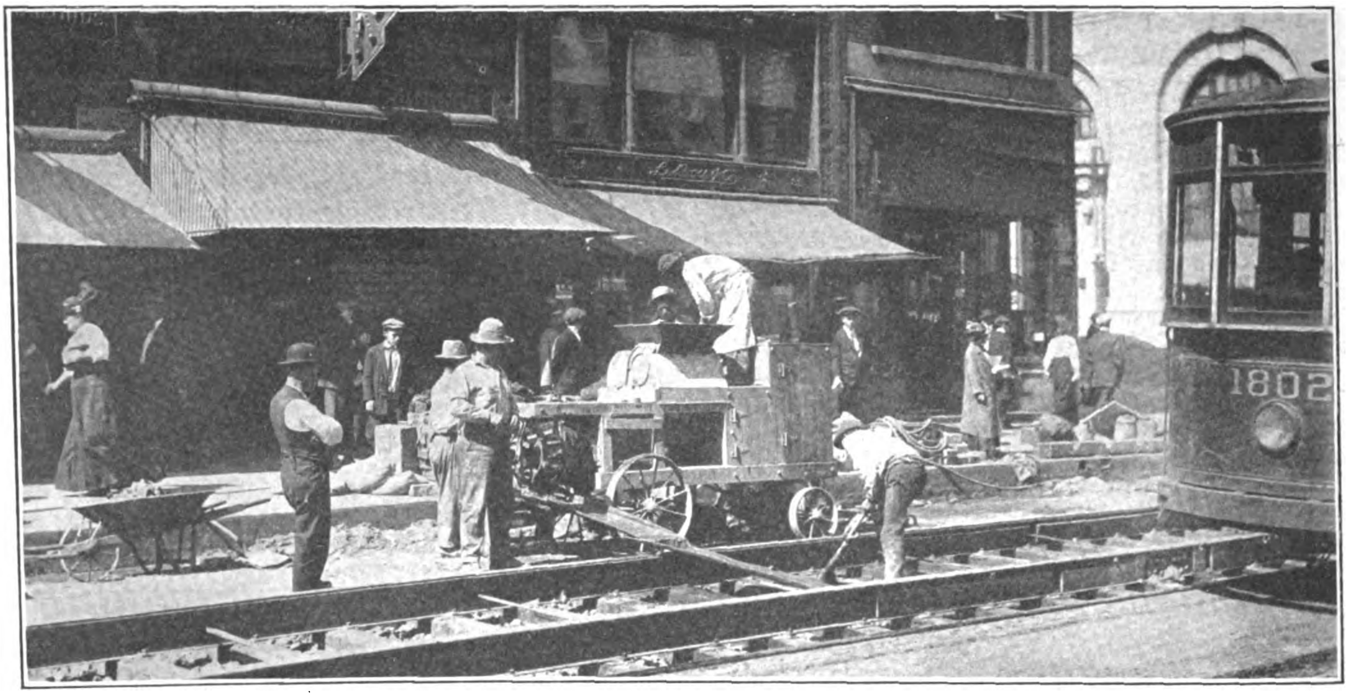
The service conditions on the Providence street railways will be indicated by characteristic runs taken on two lines, calculated on a basis of actual operation. On one line a representative average run may be taken at 8.6 m.p.h. with 8.2 effective stops per mile. The average duration of the stops is nine seconds and the average load for this run is thirty-six passengers. On another line a representative average run may be taken at 9.8 m.p.h. with 5.5 effective stops per mile. The average duration of the stops is ten seconds and the average load for this trip is thirty passengers. Completely equipped the new cars will weigh approximately 41,700 lb. They will run on 33-in. wheels and have a total seating capacity for forty-four passengers.

Raising Track under Two-Minute Headway

During the present summer the United Railways & Electric Company, Baltimore, Md., found it necessary to raise an existing track 7 in. along one of the principal trunk lines. Traffic conditions would not permit detouring cars, or even operating over a single line. Consequently the roadway department was forced to elevate the tracks, and at the same time not interrupt a two-minute headway street railway service over it. To accomplish this quickly and at the same time prepare a permanent foundation for the track, the pavement surface was removed and the track elevated to its permanent surface on crushed stone ballast.

After the track had been thoroughly tamped in position, all of which work was done between cars; the voids in the stone were filled with grout. At first the grout mixing and placing was done by hand, which required twenty-one men. Later this method was supplanted by a gasoline-driven, continuous concrete mixer of the Coltrin No. 9 type, which permitted a reduction of the gang to eight men.

Even during the grouting it was necessary to maintain car service over the track. In order to make the operation of the mixer continuous, a two-section, swivel spout was adopted. The grout in the two-section spout was deposited between the rails until a car approached, whereupon the outer section was removed and the inner section, or that connected to the mixer, deposited the grout in the space between the outer rail and the ties.

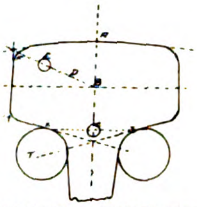


BALTIMORE TRACK ELEVATED TO PERMANENT SURFACE, AND CONCRETE MIXER IN OPERATION

In response to a query by a subscriber about London car construction, W. A. Agnew, mechanical engineer London (England) Electric Railway, advises that the "Sanit" composition flooring described on page 198 of the Aug. 1 issue of the ELECTRIC RAILWAY JOURNAL is secured to the 3/16-in. flat steel plate in some cases by cup washers riveted at intervals on the surface, and in other cases by strips of thin steel riveted to the floor and bent so as to anchor the material securely, thus ⊔ .

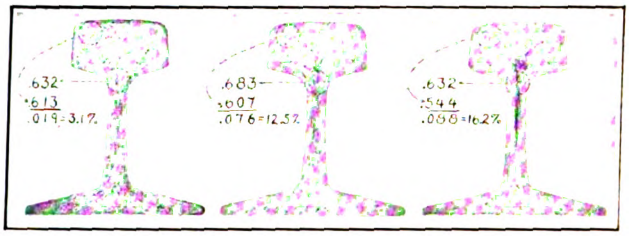
Comparative Tests of Treated and Untreated Rails

The fact that so large a company as the Brooklyn Rapid Transit Company has specified titanium for its 1914 rail work is another evidence of the popularity of the treatment originated by the Titanium Alloy Manufacturing Company, Niagara Falls, N. Y. A great many tests of these rails have been made in the past but that hereinafter described is of special interest, particularly as the total discard at the shear and hot saw from each of the twenty-four ingots tested was only 9 per cent of the steel made, whereas a discard of 30 per cent was recently necessitated by two mills in order to meet a heavy demand by a large Eastern railroad for steel, which embodied specifications set by the railroad.

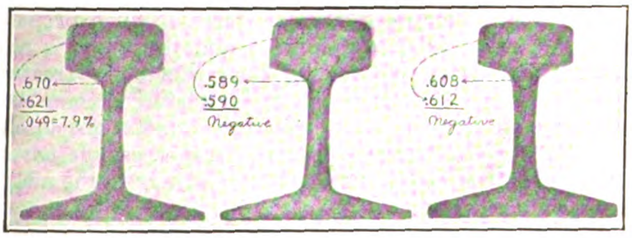


METHOD USED TO LOCATE DRILL HOLES

In view of a statement recently made by Mr. Wickhorst, the rail expert of the American Railway Association, that 50 per cent of the rail failures are due to segregation, these tests are noteworthy in showing the small variation of carbon in titanium-treated as compared with standard rails. Reproduced herewith are six out of twenty-four sulphur prints of standard and treated rail cross-sections taken from tests in which three of each kind of rails were tested at a Canadian mill and nine at a mill in the United States. The samples in each case were taken from consecutive heats of "A" rails, the sections from which they were made having been cut just below the discard of 9 per cent in each case. The dotted circles on the prints show the locations of the carbon analyses, of which the results are shown by arrows leading from the circles. The difference between the two results from each rail is given and also the percentage by which the carbon content of the lower circle exceeds that of the upper circle.



DIFFERENCES IN CARBON ANALYSES OF OPEN-HEARTH UNTREATED RAILS



DIFFERENCES IN CARBON ANALYSES IN TITANIUM-TREATED RAILS

Figures on each print show:

1. Analysis for carbon at top of web. (Exact location of ⅝ in. drill hole shown on each print.)
2. Analysis for carbon near top of head.
3. Difference between carbon analysis at each of these points.
4. Percentage such difference bears to carbon analysis for the point near top of head.

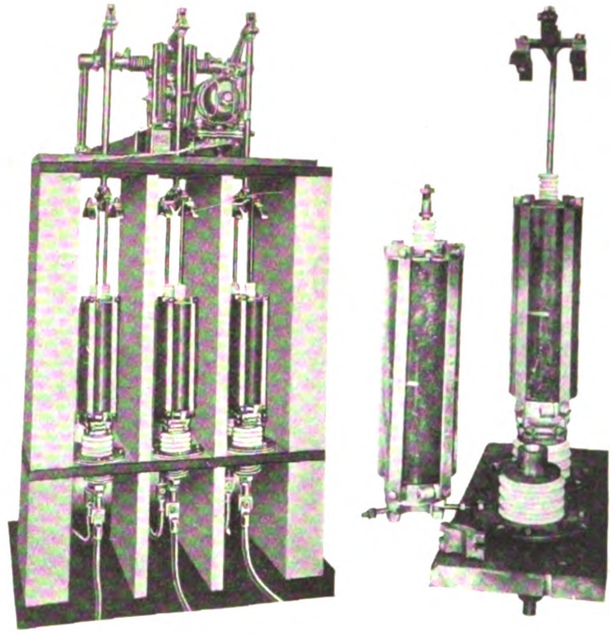
The general results from these tests show the following significant comparative data:

Standard open hearth "A" rails—Maximum variation of carbon in any one rail sample, 25.8 per cent; average variation of carbon for samples from twelve heats, 12.6 per cent.

Titanium treated open hearth "A" rails—Maximum variation of carbon in any one rail sample, 7.9 per cent; average variation of carbon for samples from twelve heats, 2.2 per cent.

Improved High-Capacity Motor-Operated Oil Switches

Recently the motor-operated type of oil switches manufactured by the General Electric Company has undergone some structural changes to make the circuit rupturing parts more accessible for inspection, adjustment or repair. The cap on the oil vessel, as well as the lower oil vessel clamp, has also been changed to allow bolting metal straps between the cap and clamp, as shown in the illustration. These straps have added great strength to the means for securing the cap in position, a valuable feature when the switch is called upon to open heavy overloads or short circuits.



15,000-VOLT 1200-AMP TRIPLE-POLE SINGLE-THROW OIL SWITCH; ALSO REMOVABLE OIL POTS AND CONTACT RODS OF SWITCH

For readily inspecting contacts and oil vessels, switches up to and including 3500 volts embody easily removable features. These are shown in the illustration of a single pole of the switch, with one of the oil vessels and movable secondary and fixed contacts removed. Any such unit can usually be removed and replaced in a short time. The operation of the renewal is as follows: Open the switch, remove the unit at the top of the contact rod, loosen the clamping nut on the cross-head and push the contact rod down into the oil vessel; then loosen one swing-bolt nut on the oil vessel lower clamp and remove the unit, consisting of the oil vessel and the fixed and secondary movable contacts.

Busbar Support with Mechanically-Cushioned Clamps

The General Devices & Fittings Company, Chicago, Ill., announces the introduction of a new line of busbar supports and porcelain fittings as hereinafter described. In developing the design special high-frequency equipment was used to determine where the porcelain should be reinforced at the voltage point and also where it should be weakened at the ground point. Further, many tests of the use of cement with porcelain led this company to adopt mechanically-cushioned clamps for its entire line because the dielectric change in porcelain due to the use of cement was considered to be a factor that causes the ageing and fatigue of porcelain carrying conductors with large currents.

This company's pyramid type porcelain bus supports are designed with small thin corrugations beginning at the voltage point and tapering wider and deeper to the ground point, primarily to reduce the electrostatic field. In view of the dependence placed on porcelain it is notable that this product is offered with a safety factor of four and a half to twelve, depending upon the service voltage impressed on the porcelain part, thus insuring low maintenance and greater security from interruptions. It is stated that busbar equipments in certain plants have shown that they are subject to a magnetic pull as high as 455 lb. per lineal foot of bus. It is therefore plain that proper bus supports should be specified to take care of these situations, since this magnetic pull would be increased tremendously through a short-circuit, inductive troubles, etc.

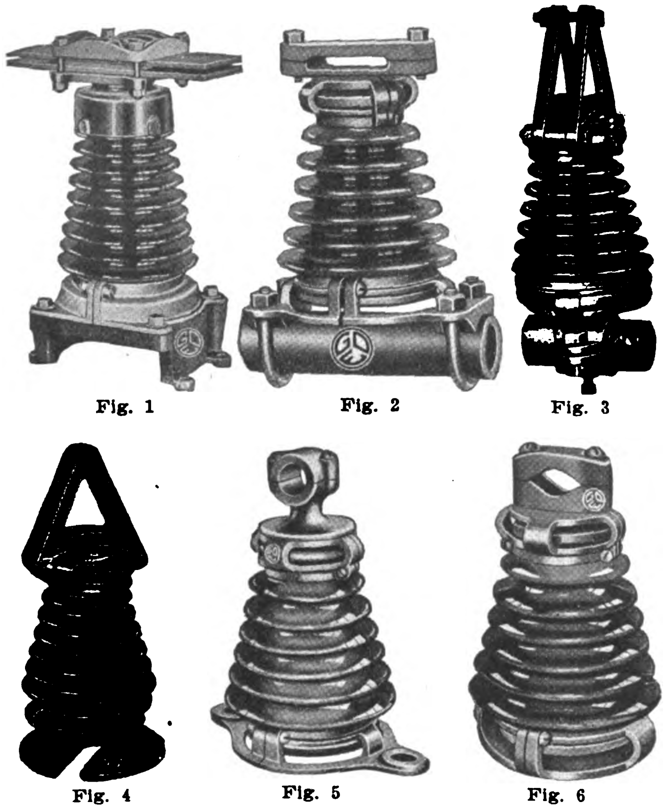


Fig. 1 Fig. 2 Fig. 3

Fig. 4 Fig. 5 Fig. 6

TYPES OF BUSBAR SUPPORTS

Referring to the accompanying cuts: Fig. 1 shows a busbar support for 22,000 volts with a guaranteed test, all assembled, of 112,000 volts. This support has a ceramic factor of 1.29, which is said to be more than 60 per cent greater than any other support on the market. An original feature is that the support is set on an insert designed to be molded into the concrete floor of the compartments. All hardware, excepting the insert itself, is made of hard bronze. This busbar support will hold a strain exceeding 1200 lb. per square inch. The cut shows two laminations of ¼-in. busbars with one filler. These supports are designed to hold any size or capacity of busbars.

Fig. 2 shows a standard busbar support equipped for holding flat buses on the horizontal and for mounting on pipe framing, this support having two U-bolts. Fig. 3 shows a busbar support for supporting buses in vertical position and for mounting on pipe framing. This pipe frame support has a set screw in the lower clamp to prevent the support from turning on the pipe and is used where supports like Fig. 2 are too wide for close work.

Fig. 4 shows a busbar support for mounting medium-sized busbar equipments in a vertical position with a flat base and center bolt clamping arrangement. It can be slipped over a bolt which has been imbedded in the concrete structure and turned in any position. Fig. 5 shows a busbar support carrying a round bus of any description. It is shown with a skeleton type base for mounting on flat surface. Fig. 6 shows a busbar support for holding large insulated cables or bare cables as the case may be, and is shown with a compartment type base. This inclosed base is hollow in the bottom and drops over a stud, which may be cemented in the compartment floor, and is widely used where height is limited.

All of the foregoing supports can be furnished with any of the bottoms or any of the tops, to suit conditions. The Fig. 1 support can be furnished either as a double support, three-way or four-way support and may be arranged to carry buses on vertical, horizontal or special tubular buses, and all supports can be adjusted to any angle simply by unloosening clamps.

A Gas Process for Cleaning Boilers

An entirely original method for the effective and total removal of scale from boilers is said to be embodied in the Pyro-Perolin process of the Perolin Company, New York and Chicago. The scale-removing system is described as consisting of an apparatus which generates and combines various gases in such proportions that when they are ignited and the flame is applied to the scale, which has been previously treated with "Perolin," the combination completely decomposes and disintegrates the scale, leaving the metal absolutely bare and free from scale even in all inaccessible parts. The combustion causes no danger of injury to the metal or tubes themselves.

After the boilers are cleaned, a liquid protective, heat-conducting film is applied to fill the pores of the metal and establish a smooth surface over the entire boiler to which scale-forming sediments cannot adhere so long as this film is maintained. This film is maintained and the boilers kept in this clean condition by a small daily feed of "Perolin" German boiler metal treatment, insuring full efficiency from the boilers at all times.

The boilers are cleaned and maintained at a definite cost per annum under a contract which includes the following provisions:

To clean any type or size of boiler within one to four days, according to the size and condition of the boiler.

To do no damage to the metal of the boiler or to its setting or attachments, subject to the inspection and approval of the boiler insurance companies.

To keep the boiler free from scale indefinitely, as long as the boiler metal treatment is used as directed. If the treatment does not do this, the company will reclean the boiler during the life of the agreement.

To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used.

To correct troubles caused by the entrance of oil and grease into the boiler.

Motor Driven Car Hoist and Wheel-Changing Device

The motor-driven screw hoist of the Columbia Machine Works & Malleable Iron Company, Brooklyn, N. Y., has been installed in a large number of electric railway shops, but its construction details have hitherto not been described. As the company, however, has recently patented some new features, the accompanying drawing and particulars should prove of interest. The car hoist is usually built for a longitudinal spacing of 24 ft. between the hoisting members, but it has been constructed for a spacing of 36 ft. and, in fact, can be made to handle city and interurban cars of any length. The standard form of drive is through the bevel-gear and worm transmission illustrated, and any old-time traction motor is of ample capacity for the work. Ordinarily a car may be raised at the rate of 1 ft. per minute. The worm wheel shafting is inside or outside as the user prefers.

One recent improvement is the support of each vertical screw by a bushing to give the screws a good bearing and prevent swaying as they go upward. Another change is the attachment of straps to the 12-in. I-beams above the lifting screws in order to support the wooden cross-beams on which the car body is raised and also for the purpose of adding strength to the I-beams.

The new patented car-wheel changing device shown in the other drawing is fitted with the same type of worm and screw lift as the car hoist except that one instead of four screws are required. The platform consists of two cross and four longitudinal 8-in. I-beams with top and bottom stiffening plates. The platform will readily carry 2000 lb., a weight far in excess of electric railway wheel sets. Long guides are provided at the sides to prevent tilting when a car is run on or off the wheel-changing track. The standard form of drive is by means of any small motor, but in a recent order this device was made for hand operation through chain and sprocket drive. The latter method, however, requires about five minutes in a case where the motor will do the work in one-half the time. The user can readily install automatic cutouts if he fears that a careless workman would permit a motor-driven screw to overrun in either direction.

TOLEDO INJUNCTION GRANTED

Judge Killits Scores Previous City Administration, Holds Three-Cent Fare Confiscatory and Says Use of Police to Enforce Three-Cent Fare Would Have Been Misuse of Power—Political Trickery Charged

On Sept. 12 Federal Judge Killits at Toledo, Ohio, held that the Schreiber ordinance prescribing a 3-cent fare for the Toledo Railways & Light Company is unreasonable, unfair and confiscatory; that the ordinance should be declared invalid; that free riding, which began on March 27, should cease at noon on Sept. 15; that the company can remove cars from lines on which franchises have expired without interference from the city, and that the company can store its cars where it pleases. He issued an order temporarily restraining the city from enforcing the ordinance. The restraining injunction reads as follows:

"It is accordingly ordered by the court that the city of Toledo, its officials, agents, employees and all other parties and persons whomsoever, to whom notice hereof is or may be given, and each of them, are hereby enjoined and restrained, until the further order of this court, from asserting, enforcing or attempting to assert or enforce, the rates of fare, or any of the terms and provisions of a certain ordinance, passed by the Council of Toledo on Nov. 24, 1913, as set forth in paragraph eleven of the amended cross bill filed herein by the defendant, the Toledo Railways & Light Company, by which ordinance it was provided that the Toledo Railways & Light Company should not charge to exceed the sum of 3 cents for each passenger; and the said person and parties, and each of them, are hereby further enjoined and restrained, until the further order of the court, herein from interfering and attempting to interfere with the withdrawal by the defendant, the Toledo Railways & Light Company, should it attempt to do so, of its cars from the streets of the city of Toledo upon which its franchises have expired, and the storing of said cars by defendant, the Toledo Railways & Light Company, in such place as it may deem best. It is ordered that the foregoing injunction and restraining order shall go into effect at 12 o'clock noon on Sept. 15, 1914."

Judge Killits reviewed the previous hearing and called attention to a number of defects in the ordinance. He also criticised the former city administration for passing the ordinance. The decision rendered by him reads in full as follows:

"The first motions in this case for temporary injunctions to restrain the operations of the so-called Schreiber ordinance were denied because then the city was neither attempting to enforce it nor by its terms allowed to enforce it except through an order of a competent court before which the complainants could charge and prove, if possible, that it was confiscatory and consequently invalid. The consequence of this opportunity to the complainants to resist an order of enforcement left this court powerless to apply the extraordinary remedy of injunction. The court then had jurisdiction of the main case, to which the motions were plainly ancillary.

"It is unnecessary to cover again in full the discussion then had of the relative rights of the company on the streets without franchise, and the city. It is sufficient here to say only that the company might run its cars from day to day, until forbidden by the city, at such rate as it was able to collect, and that it had the right to charge a rate that would pay its operating expenses and leave a surplus equal to a fair return upon its real investment, and further, at any time the company might discontinue service, take its cars off the streets altogether, and remove its tracks. The city, on the other hand, might either forbid the company absolutely the use of the streets, or, permitting the use, impose therefor reasonable regulations respecting service and rates of fare.

"The ordinance in question never having been accepted by the company, the initiative for enforcing it was upon the city, and that fact was recognized by its author in the provision directing the city solicitor to go into court for an order on the company to observe it. It is not an ordinance which the city can enforce through its police power.

"Conditions have changed radically, however, since last March. During the intervening months the city's executive, neglecting the direct and only proper method of enforcement which the ordinance itself provided, but which involved a decision of the contention loudly urged by the company that it was oppressive and unreasonable, attempted indirectly its enforcement through an encouragement of reliance upon its terms by individuals.

"The uncontradicted evidence in this hearing shows that, taking the indefensible position that the measure was self-enforcing, the officers of the city assumed an attitude of sustaining private judgment, even to the extent of suggesting that the power of the city would be employed to assist any individual who attempted to enforce his opinion of his rights under it. This was a wholly indefensible position. To have placed a policeman at the call of any individual, to enforce his judgment that he should ride at 3 cents, would have been as flagrant an abuse of power as to have given the same individual police aid to enforce any other private right which he assumed to have without any other adjudication than his own consideration.

"By the ordinance itself, the company was given the right to question its obligations thereunder in a duly constituted general forum for the adjudication of responsibilities, and was not obliged to submit to the view of any person who chose to board its cars. The effect of the city's attitude, however, was practically an enforcement, and the company was faced with the alternatives of submitting without a test or of suffering innumerable annoyances and suits in the nature of damages, and, in all probability, violence. It is to deal with precisely these situations that courts of equity are open to suitors of any class, and this corporation, as is the case with any individual person, is under the protection of the guaranties of the federal constitution.

"We hold, therefore, that the court may now, as we could not before, inquire into the charge that the ordinance is confiscatory in its effect, and, if we find the facts clearly sustaining the charge, we may apply the extraordinary remedy of injunction.

"This ordinance, as in the case of any other legislation, is favored by every presumption. It is presumed that the public agencies concerned in its production acted intelligently, honestly and providently, and that its terms are reasonable and fair. The fact that a piece of legislation enjoys these presumptions does not, however, make it invulnerable. It may still be attacked in any of these particulars, the presumptions having the effect only of testimony of validity, wherefore clear evidence against it may be adduced to overcome them and to set it aside. The court also, while bound to indulge these presumptions, may look to the surroundings for a measure of their strength.

"The law of Ohio provides rules to secure deliberation in the passage of ordinances of this kind. Three readings on three different dates are required to precede the adoption of such a measure, unless some emergency or other proper reason impels a suspension of the rules by a three-fourths vote of the Council.

"This measure, not intended to go into effect for four months and not for three months after the incoming of a new Council and a new administration, was passed to adoption through three readings at one sitting by Council and urged by an administration whose friends had just suffered defeat at an election.

"These circumstances suffice to start speculation upon the value of the presumptions. When, however, we find, as the testimony here shows without dispute, that, at the time this ordinance was passed and signed, the executive of the city was not only possessed of statistical information in most illuminative detail from its trusted expert, which, properly considered, showed that a 3-cent fare was confiscatory, but that also the force of such statistics to this effect was pointed out in advice privately given in writing and orally by this expert to the executive, with reasons why a 3-cent ordinance should not be passed, and, further, that the city had, in November, 1913, no evidence or light whereon to base a fixing of rate except that given it by its own chosen expert to the above effect, it does not take a very acute mind to see that these vaunted presumptions descend nearly to the level of mere legal figments.

"However, the court on this hearing honored them to the full by requiring the movants to sustain the burden of their charge that the ordinance was unreasonable by clear evidence, and it was not until, through the testimony of the city's own expert, Mr. Nau, and a showing of the experience of the company, a volume of evidence was had which demanded that the city produce support for the failing presumptions upon which it relied, that the court required any action at all by the city. Every possible facility was afforded the city to support the ordinance, the court adjourning the hearing for five weeks for that purpose. The record now shows in evidence comprehensible to every intelligent man, and derived from testimony in which there is absolutely no dispute, that this ordinance is unfair and that to attempt to enforce it is to attempt confiscation.

"The city solicitor, after struggling against the inevitable as long as possible, finally, and commendably, confessed that it was impossible either to get any other evidence than that before the court or to draw any conclusion from the testimony, which he could not dispute, than that at the rate of 3 cents the company's revenue would do no more than barely pay running expenses, leaving nothing for a return upon the investment. There are some lines in the city on which a fare under 3 cents would pay operating expenses; there are lines on which 6 cents and even 7 cents would not even pay expenses. There is one line whose revenue does not meet one-third of its expenses, and others whose returns are but one-half to two-thirds of their outlays.

"Averaging all the lines, if the public insists upon the present routing, any man capable of doing sums in simple arithmetic can see that an average rate of 3 cents is too low. It is demonstrated from the record that if every person who has ridden on the cars since March 27 last, whether he had paid or not, had paid 3 cents, the income of the company would barely have equaled its expenses, and the months since March are the months of a year when traffic is the heaviest and expenses the lightest.

"It is beyond dispute from this record that this ordinance is unreasonable and unfair, wherefore it should be declared invalid, and an order to that effect may be entered."

Wesley S. Thurstin, Jr., city solicitor, issued a statement in regard to the decision. This statement he concluded as follows:

"While we inherited the Schreiber ordinance from Mr. Whitlock's administration, we maintained our position that it was a legal ordinance and that it was passed in good faith until we discovered, during the trial in the United States Court, that Mr. Whitlock and Mr. Merrill, then chairman of the railroad committee of Council, and various other gentlemen in the Whitlock administration, had been apprised of the impracticability of the measure and then we abandoned our contention that the ordinance had been passed in good faith, and became fully aware of the political trickery that fathered it.

"Some working arrangement or day to day agreement will have to be enacted, carrying in mind the result of the Nau and Clark reports, and furthering the placing of the traction system on a more businesslike basis, and this should be done with as little delay as possible; also bearing in mind that the citizens of Toledo are entitled to the best conscientious efforts of the officials to settle this grievous question and remove it from politics for as long a period as possible."

In the leading editorial, "Judge Killits Performs Invaluable Service," in its issue of Sept. 13, the Toledo *Times* said:

"Judge Killits, in enjoining the city of Toledo from enforcing the Schreiber 3-cent fare ordinance, has performed an invaluable service for the community. He has brought the traction question to an issue, which must of necessity lead to a speedy settlement. He has removed a political public bugaboo that has hampered the growth of Toledo for some ten years. And the judge has effectively silenced a political war-cry which has kept the city on the ragged edge of nowhere for the same length of time. The Schreiber ordinance has been proved unreasonable and confiscatory. The city solicitor, manfully, has admitted it. Judge Killits' decision must put Toledo on the upward trend. By bringing a prompt settlement of the traction question, it will re-establish the city in the eyes of many men at the head of big industries in other places, who have long been afraid to bring those industries here."

Former City Solicitor Schreiber issued a statement in part as follows:

"The 3-cent ordinance was passed after most mature and careful consideration, and in the highest degree of good faith, with certain vital and basic legal principles in mind. Not one of these fundamental principles was even mentioned in the trial of the cause. Had these points been earnestly presented to the court, doubtless a different result could have been expected. I cannot but feel that had the proper additional legal talent been employed, the city would to-day find itself in a far more advantageous position. I am quite convinced that the citizenship of Toledo is not satisfied with the solicitor's unconditional surrender and that it demands that the twelve years' fight shall not be given up without a more serious struggle."

The company prepared to post in its cars just before noon on Sept. 15 the following notice:

"Rates of fare: Cash fare, 5 cents; tickets good at all hours, six for 25 cents; tickets good only between 5:30 a. m. and 7:30 a. m. and 4:30 and 6:30 p. m., five for 15 cents, or three pennies; children eight years old or under, 1 cent; children in arms, free."

It was also proposed to hand each car rider a handbill bearing the same notice. President F. R. Coates said that, not anticipating any trouble on Sept. 15, he has issued no special instructions to the conductors other than to collect regular fare from all passengers.

The police department was instructed to see that there was no disorder on the cars when the change went into effect. On Sept. 15 Harry J. Howard, managing editor of the Toledo *News-Bee*, was cited for contempt of court by Judge Killits. In the order served upon him Mr. Howard was directed to appear on Sept. 16 to show cause why he should not be punished for certain utterances in the editions of the *News-Bee* of March 25 and Sept. 12, 1914, relative to the case then pending in the United States Court on the application of the company for a temporary injunction to prevent the enforcement of the Schreiber 3-cent fare ordinance. The court also objected to certain statements in the *News-Bee* regarding John Quinlivan, labor leader, and the contempt case against him in the United States Court. In an address Mr. Quinlivan referred to the court in such a way that he was cited to appear and explain the meaning of his remarks.

NEW SUBWAY STATION AT GRAND CENTRAL TERMINAL IN NEW YORK

The Public Service Commission for the First District of New York will open bids on Oct. 6 for the construction of the so-called diagonal station under Forty-second Street, in front of the Grand Central Station. This station will be built upon the line connecting the existing subway just south of Forty-second Street with the new Lexington Avenue subway just north of that street. Bidders will be required to deposit a certified check for $75,000 with their bids, and the contractor will be obliged to give a bond for $500,000 to the city and one of $250,000 to the Interborough Rapid Transit Company. The work of construction must be completed within twenty-eight months from the delivery of the contract. The station, which will occupy almost the whole length of the new line, will be one of the largest underground stations in the world. It will be more than 100 ft. wide, with two platforms serving four tracks, and the walls will be built to support a twenty-five story building on the site of the old Grand Union Hotel. A concourse will be built above the level of the station, and this concourse will connect with the Grand Central Station, the Steinway Tunnel, the Lexington Avenue subway, the existing subway and the Hudson & Manhattan Railroad tubes when extended to Madison Avenue. The connection with the Steinway tunnel, which is at a lower level, will be by elevators, and transfers will be given between the tunnel line and the old and new subways.

RESUMPTION OF SEATTLE PURCHASE NEGOTIATIONS LIKELY

By a vote of six to three, the City Council of Seattle, Wash., on Sept. 9 decided to open negotiations with the receivers for the purchase of that portion of the Seattle, Renton & Southern Railway lying within the city limits at a maximum price of $1,600,000. The plan proposed provides for an initial payment of $200,000 in municipal street railway bonds, bearing 4½ per cent interest, authorized several years ago and from which Division A of the present municipal railway was constructed, and an annual payment on the remaining $1,400,000 of 25 per cent of the gross earnings for a period of twenty-five years. In the event the $1,400,000 is paid before the expiration of the twenty-five years, title to the property immediately passes to the city without further payment. In the event the $1,400,000 has not been paid at the end of twenty-five years out of 25 per cent of the gross earnings, further payments are to cease and title to the property becomes absolute in the city.

When negotiations were conducted several months ago on a basis of the receivers accepting 25 per cent of the gross earnings for a period of twenty-five years, regardless of what amount that might be, the Mayor suggested that a maximum price for the property be fixed by the receivers beyond which the city should not be required to make payment. Receiver Scott Calhoun at that time announced that he was not in position to fix a maximum figure on such a basis. On Sept. 9 he announced his willingness to open such negotiations, explaining, however, that he would have to submit the proposition as finally agreed upon to the bondholders and the court for their acceptance or rejection.

In view of the possibility that the city may become the owner of the railway at the conclusion of these negotiations, Corporation Counsel James E. Bradford was directed by the Council to ask for a continuance of the Empire Way condemnation proceedings until Oct. 1. Purchase of the Seattle, Renton & Southern Railway would destroy the need for any such car line, and the Council is apparently in a mood to drop the condemnation proceedings if it is found possible successfully to negotiate the purchase of a going car line. It was proposed at one time to have the city experiment with motor buses or establish a competing line.

POWER CONTRACT OF NEW HAVEN RAILROAD

At the regular monthly meeting of the board of directors of the New York, New Haven & Hartford Railroad, held in New York on Sept. 17, the officers were authorized by the board to purchase power from the New York Edison Company. This purchased power, together with that now obtained from the power plant of the New York Central Railroad and of the New Haven Railroad at Cos Cob, will increase the number of trains handled electrically between New York and New Haven from 37 per cent to 70 per cent of the total. In order to have 100 per cent of electrical operation it will be necessary to purchase additional electrical equipment and additional power in the eastern section of the electric zone between New York and New Haven. The latter project is something which cannot be undertaken under present financial conditions.

It is expected that the contract for the purchased power will be signed within a few days.

EXTENSION OF SAFETY ZONES IN LOUISVILLE

The safety zones which have been used experimentally for the last few weeks at important intersections to protect persons boarding street cars in Louisville, Ky., has been found so successful that the zones will be established elsewhere in the city. The plan was first used at Fourth and Walnut Streets, where probably the greatest congestion occurs. It is now proposed to establish zones at Fourth and Green Streets and Fourth and Chestnut Streets and eventually to equip the entire downtown district in the same way. In order to keep the standards from blowing over, larger bases are to be used. The standard is placed in the street between the cartracks and the curb, and just back of the point where the rear of the car, after it stops, is located. At the entrance to Cave Hill Cemetery, at Baxter Avenue and Broadway, a barrier will be erected consisting of a hand rail supported by iron or wooden standards, behind which persons may walk with safety on their way to or from cars.

NEW MUNICIPAL LINE OPENED

The municipal railway from Van Ness Avenue along Market Street and Potrero Avenue to Twenty-fifth Street, San Francisco, Cal., has been completed. The line was formally opened for business on Sept. 7.

Referring to the plans for operating the line the San Francisco *Municipal Record* said:

"C. A. Cashin, superintendent of the city railways, will have every car of the system in operation on Sept. 7, and while the full complement has not as yet arrived, he hopes to be able to handle the throngs which it is expected will crowd the city lines on that day. Of the 125 new cars which have been ordered thirty-two will be ready for service on Sept. 7, which, with the forty-three built for the Geary road, will make a total of seventy-five cars in operation.

"The line to be opened and operated directly in connection with the Van Ness Avenue line to the north bay shore and the Exposition grounds extends from the foot of that line across Market Street and down Eleventh Street by way of Division Street and Potrero Avenue to Twenty-sixth Street, a distance of 2 miles.

"The cost of construction for installation of track, grading and paving was $126,000. This work has been completed, not including unavoidable delays, in less than ninety days' time. On Potrero Avenue, between Sixteenth and Mariposa Streets, the city has joint use of the tracks of the Ocean Shore Railroad, for it was one of the conditions when that corporation was given a franchise that the city should have the use of the tracks by paying its proportion of maintenance.

"Following the formal opening of the road Superintendent Cashin expects to maintain a five-minute headway until the arrival of more cars permits a headway which will be arranged to suit the demands of the traveling public."

LEASED COMPANIES SEEK RECOVERY OF FEDERAL INCOME TAX

Transcripts of the records of the cases of the Columbus, Newark & Zanesville Electric Railway, the Fort Wayne, Van Wert & Lima Traction Company, the Cincinnati Street Railway and the Indiana, Columbus & Eastern Traction Company against Andrew C. Gilligen, collector of internal revenue, and the Columbus, Newark & Zanesville Electric Railway and the Dayton & Western Railway against Bernhard Bettmann, former collector of internal revenue, were filed recently in the United States Court of Appeals at Cincinnati from the United States District Court. The appeals were taken on error from the judgment of United States District Judge John E. Sater, denying certain causes of action contained in the petition for the recovery of the excise taxes assessed and collected for the various years since the passage of the federal corporation income tax law and ruling that the companies had done business within the meaning of the law and were not entitled, therefore, to refunds of the taxes paid.

The properties of all of the companies concerned in these cases are leased to the Ohio Electric Railway and the latter companies sought the recovery of the taxes collected from them, on the ground that as lessor companies they were exempt from the excise tax. The government contended that, notwithstanding the fact that the properties were operated under lease, the companies had exercised corporate powers in the issuance of capital stock, sale of real estate, prosecution of suits, etc., and were, therefore, liable for the payment of the excise tax. The Court of Appeals will be called upon in these cases to decide what constitutes an act of business under Section 38 of the federal income tax law.

CLEVELAND STOCK INCREASE AND LABOR PROBLEMS

The application made recently by the Cleveland (Ohio) Railway for permission to add $1,068,500 to its capital stock was granted on Sept. 15 by the Ohio Public Utilities Commission.

A delegation of Kinsman Road citizens appeared before Council at a recent meeting to urge an extension of the new East Seventy-ninth Street line from Woodland Avenue to Kinsman Road. Peter Witt, street railway commissioner, said that the extension would be made next spring.

The street railway committee of the City Council has announced that hereafter Mr. Witt will be asked to furnish the committee with a tabulated statement showing the bids on any improvement to be made by the company, before expenditures of funds for such purposes are approved.

Members of the local branch of the Amalgamated Association of Street & Electric Railway Employees are uncertain as to the possible results of a difference that has arisen between P. J. Shea, chairman of the international executive committee, and George R. Davies, president of the local branch. Mr. Shea came to Cleveland to aid the local officials in their endeavor to secure a change in working hours and an advance in wages. As a result of his conferences with members of the union the idea has spread that an attempt was being made to oust Mr. Davies from office. W. D. Mahon, president, has been asked to visit Cleveland and assist in settling the differences in the local organization.

Boston's New Subway.—Sept. 26 has been set as the date for the opening of the new Boylston Street subway in Boston. Trial and instruction trips will be conducted from Sept. 21 until the regular opening date.

Progress of Norfolk & Western Electrification.—According to L. E. Johnson, president of the Norfolk & Western Railway, the work of electrifying the line between Bluefield, W. Va., and Vivian, W. Va., a distance of about 30 miles, is proceeding satisfactorily, and it is expected that the line will be ready for electric operation in January, 1915.

Pittsburgh's Subway Proposal.—The committee on public service and surveys of the Pittsburgh (Pa.) Council decided to meet each Monday to consider the pending subway proposals so as to dispose of the matter by Oct. 1 if possible. The Council has posted notices at the Exposition giving the reasons for the delay in connection with the subway grants.

Rehabilitation of Iowa Road Completed.—The Centerville, Albia & Southern Railway, formerly the Southern Iowa Traction Company, has completed the change in motive power from steam to electricity and is now operating six passenger trains and one freight train each day between Centerville and Albia, giving convenient connection with the Chicago, Burlington & Quincy Railway main line trains.

The St. Paul Electrification.—A. J. Earling, president of the Chicago, Milwaukee & St. Paul Railway, in the annual report of the company for the year ended June 30, 1914, refers to the electrification progress as follows: "Electrification of the Puget Sound line was started in April, 1914, and on June 30, 1914, 30 miles of poles were ready for wiring. It is expected that stringing wires from Three Forks to Deer Lodge will be completed by July 1, 1915."

Reconstruction Work Resumed.—Construction work has been resumed on the London & Port Stanley Railway. The Pere Marquette Railway, which has the contract for building the new roadbed, refused to assume responsibility for accidents, and was instructed by the committee to vacate the line. The company's representative later consented to go on with the work. All the new rails have been laid, but the company has yet to put in the new ties and the ballast.

Franchise Election Proposed in Des Moines.—The City Council of Des Moines, Ia., has adopted a resolution granting the Des Moines City Railway permission to place its franchise proposal before the voters. Emil G. Schmidt, president of the company, announced that the circulation of petitions would be taken at once with the idea of completing the preliminary canvass by Sept. 15. The matter will then be submitted to the Council, and if it acts promptly the date of the election will probably be set for some time in October. The expense of the election will be borne by the company.

Illinois Commission Sues Elevated Railways.—Last spring the Illinois Public Utilities Commission ordered the Chicago & Oak Park Elevated Railway to elevate its tracks in Oak Park, Ill. The attorneys for the railway contended that the company could not obey the order of the commission since it was in the hands of a receiver and subject to the order of Federal Judge Carpenter, of the United States Court. As the court has not issued instructions to the company regarding the order, the commission has arranged to file suit in the United States Court to force the company to comply with its ruling. In making the order the commission gave the company the option of stopping its cars at all grade crossings in Oak Park, or elevating its track.

The Kansas City Storm.—The Metropolitan Street Railway, Kansas City, Mo., was one of the heavy sufferers from the severe rainstorm of Sept. 7. Traffic on some lines was suspended for several hours in the morning because of power plant trouble and water and débris on the tracks. One carhouse was partly submerged. Motors of some of the cars that coasted through depressed areas where water was 2 or 3 ft. deep were put out of service, and it was a record day for "pull ins." Despite the obstacles, complete service was restored by evening, and by Sept. 10 all the equipment was ready for service again. There was little wind and few trolley wire troubles. The day after the storm the company used newspaper display space to announce the resumption of regular schedules.

Solano Project to be Revived.—It is stated that the Solano land project, which was taken up by the United Railroads of San Francisco during the connection of Patrick Calhoun with the company, will be revived. Jesse W. Lilienthal, now president of the United Railroads, is quoted as follows: "I believe that Solano will prove to be a great project if it can be handled properly. I have my heart set on reviving it and will bend every effort now to that end. I am convinced that Frederick Van Vorst, attorney for the United Railways Investment Company, who has made himself thoroughly familiar with the conditions in San Francisco, will be able to help us a great deal when he returns from the East. The plan would be to take a tract of, say, 15,000 acres and build up the project from this."

Storage Battery Service on Central Vermont.—It was announced that electric service on the Central Vermont Railroad would be established on Sept. 14 between Brattleboro, Vt., and Millers Falls, Mass., and Brattleboro and West Townsend with the storage battery cars which were tried out a few days ago. The proposed schedule is to leave Brattleboro at 5:20 a. m., arriving at Millers Falls in time to connect with the train which arrives at Boston at 9:30. The car will return to Brattleboro on the arrival of the train which leaves Boston at 6:30 in the morning and will arrive in Brattleboro at 11:20 a. m. The car will leave Brattleboro for West Townsend at 2:30 and arrive there at 3:50, and will start on the return trip at 4:20, arriving at Brattleboro at 5:40. The car will leave Newfane at 4:55. It is said unofficially that the electric service will probably be made permanent if the proposed experimental period of a month proves it successful.

Furthering Philadelphia's Transit Plans.—The finance committee of the Councils of Philadelphia, Pa., is reported to have reconsidered its position on the transit question and will grant $500,000 to Director of Transit Taylor for preliminary transit work. The appropriation, it was said, would be made by transferring the bulk or all of the amount needed from the item allowing $1,000,000 to a municipal art gallery. When Councils adjourned for the summer vacation they did so to meet again in October. This plan was abandoned, however, following Mayor Blankenburg's emphatic statement that the loan should be rushed through as quickly as possible. It is understood that Mayor Blankenburg will consider the matter of sending a special message to Councils urging upon them the necessity of including in the loan bill the item of $500,000 requested by Director Taylor for preliminary transit work. In a strong appeal to Councils, to the finance committee and the public in general, Director Taylor has again reviewed the transit situation and set forth clearly and concisely his plans for beginning the work at once. The director also announced new surface lines in various parts of the city. They include a crosstown line on Forty-sixth Street, additional lines above Frankford, a new line on Chew Street, extensions to the South Philadelphia north and south lines, additional lines north of Girard College, a direct line to Roxborough, a line on North Ninth Street and a direct line to Fox Chase.

Special Massachusetts Commission Appointed.—Governor Walsh of Massachusetts has appointed the commission "to consider the improvement of transportation facilities in the commonwealth, with especial reference to the five western counties," as provided for by a legislative act approved on July 2. Louis C. Hyde, chairman, William G. McKechnie, Samuel D. Sherwood and Richard J. Talbot, all of Springfield, and Henry J. Ryan, Pittsfield, will compose the commission. Politically the commission consists of one Republican, three Democrats and one Progressive. The field of operation of the commission is exceedingly broad. It is to consider the needs, possibilities and probable benefits, both to the commonwealth and the five western counties, of a development and extension of transportation facilities, and of the utilization of the agricultural, dairy and stock raising opportunities of these counties. It is to study also the causes and remedies for the diminution of population, and the decline of industries and agriculture. It is expected to determine the best method of securing transportation facilities, including the feasibility and probable cost of construction to the commonwealth of a system of railroads, electric railways or State highways to serve and promote the development of the five counties. The commission is obliged to give public hearings and to report its conclusions and recommendations to the Legislature not later than Jan. 15 next, together with drafts of such bills as it may deem expedient. The Legislature has authorized the expenditure of $10,000 for the purposes of the commission, including the compensation of its members.

PROGRAMS OF ASSOCIATION MEETINGS

Federation of Trade Press Associations

The ninth annual convention of the Federation of Trade Press Associations will be held at the Congress Hotel, Chicago, Ill., on Sept. 24, 25 and 26. The principal purpose of the convention is to develop a higher standard of efficiency in the management of business and in marketing methods. The session of the morning of Sept. 24 will be devoted to the address of welcome and to the regular business of the association. In the afternoon there will be an editorial symposium and a circulation symposium. On the morning of Sept. 25 there will be an advertising symposium and in the afternoon a subscribers' and advertisers' mass meeting. The annual banquet will be held in the gold room at the Congress Hotel at 6:30 p. m. on Sept. 25. On the morning of Sept. 26 there will be a publishers' symposium. Following this the convention will be concluded with the final business session.

Railway Signal Association

The program has been announced for the nineteenth annual convention of the Railway Signal Association to be held at the Hotel Champlain, Bluff Point, N. Y., on Sept. 22, 23 and 24. Committee reports will be presented as follows: committee one, signaling practice; committee two, mechanical interlocking; committee three, power interlocking; committee four, automatic block; committee five, manual block; committee six, standard designs, signal symbols and nomenclature; committee seven, subjects and definitions; committee eight, electric railways and a.c. signaling; committee nine, wires and cables; committee ten, storage battery and charging equipment. There will be special committee reports on methods of recording signal performance, signaling requirements of electric railways, and lightning protection.

The meeting will be opened at 10 a.m. on Sept. 22 with an address of welcome. The program calls for the presentation on that day of the reports of committees one, three, four, nine and ten, also the report of the special committee on methods of recording signal performance. On Sept. 23 the reports of committees six, seven and eight will be presented, and on Sept. 24 the reports of committees two and five will be presented, together with the report of the special committee on signaling requirements of electric railways.

An elaborate program of entertainment has been arranged. This includes tennis, croquet and golf competitions, a boat trip on Lake Champlain, a trip to Au Sable Chasm and a boat trip through Lake George.

Financial and Corporate

RECENT FINANCIAL TENDENCY

Trading in Bonds Resumed, New York City Loan Arranged and War Revenue Tax Bill Being Redrafted

On Sept. 10 the committee of seven bond dealers chosen to act for the investment bankers of New York during the suspension of business on the Stock Exchange decided to recommend the resumption of trading on a restricted scale. The committee said that the completion of arrangements for the New York City loan had improved conditions materially and that dealers were justified now in selling securities to their customers where this could be done without disturbing the collateral loan situation. Subsequently the committee emphasized its opinion that for the time being all dealings in bonds should be restricted to those owned by the houses making the sale, that sales should only be made to their private customers, and that all brokerage and semi-brokerage transactions between houses in an endeavor to fill any orders on bonds which they did not own should be strongly discouraged for the time being. Following the lead set in New York the matter of resuming bond trading was taken up in both Chicago and Philadelphia, but up to Sept. 16 the rules to govern transactions in these cities had not been formulated.

Cable advices from London dated Sept. 14 said that the opening of the exchange there would probably be effected within a month, and on Sept. 15 the Stock Exchange committee there fixed prices for nearly 1000 British, Indian and Colonial gilt-edged securities and other trustee securities. Sales are forbidden below the prices so fixed. Transactions must be for cash.

The Board of Estimate and Apportionment of New York has approved the contract with J. P. Morgan & Company and Kuhn, Loeb & Company, as syndicate managers, covering a loan of $100,000,000 by a syndicate of banks and trust companies to New York City on one, two and three-year securities at 6 per cent. The board also has adopted a resolution covering the method for refinancing these securities as they mature and improvement work up to Jan. 1, 1918. The amended plan provides that improvements authorized during 1915 which are not self-sustaining are to be paid for 25 per cent from taxes and 75 per cent by issue of one to fifteen-year corporate stock. Improvements authorized during 1916 will be met 50 per cent from the tax budget of the next year and 50 per cent by sale of serial stock; during 1917 they will be paid 75 per cent from the budget and 25 per cent by serial stock, and in 1918 the full cost will be met from taxes. Shipments of gold to Canada have already been made in connection with maturing obligations of New York City in Europe.

The Federal Reserve Board at its meeting on Sept. 12 renewed consideration of the report of the committee in favor of establishing a fund of $150,000,000 in gold for protection of the foreign exchange situation. In view of the announcement that New York City had completed arrangements for payment of its maturing obligations and for providing for the necessary gold remittances to Europe the board decided to await developments before giving the matter further consideration.

The war revenue bill was reframed on Sept. 16 to eliminate the freight tax and provide special levies. In addition to the taxes on wine, beer and gasolene already agreed upon, the plan is to tax banks with capital and surplus not exceeding $25,000 $50 a year and $2 for each additional $1,000; stock brokers, $50; pawnbrokers, $20; commercial brokers, $20; custom house brokers, $10; proprietors of theaters, museums and concert halls, $100; circuses, $100; public exhibitions, $10; bowling alleys and billiard halls, $5 per alley or table; dealers in leaf tobacco, $6 to $24, according to volume of business; dealers in tobacco, $12; manufacturers of tobacco or cigars, $6 to $24. The stamp taxes so far proposed are subject to probable revision by the committee.

The London *Economist* of Sept. 5 contained a review of industrial conditions in Germany written in London by the Berlin correspondent of that paper. Stagnation in practically all lines is reported, with grave danger pending of a depletion of the food supply.

ANNUAL REPORT

United Light & Railways Company

The comparative statement of income, profit and loss of the United Light & Railways Company, Grand Rapids, Mich., for the years ended June 30, 1913 and 1914, follows:

	1914	1913
Earnings available on securities owned of subsidiary companies	$1,366,543	$1,234,736
Miscellaneous earnings	124,811	86,515
Gross earnings	$1,491,354	$1,321,251
Expenses and taxes	97,384	79,931
Net earnings	$1,393,970	$1,241,320
Interest charges	401,598	337,976
Net income available for depreciation and dividends	$992,372	$903,344
Pro-rata dividends—first preferred stock	458,367	362,741
	$534,005	$540,603
Pro-rata dividends—second preferred stock	69,565	89,930
Balance	$464,440	$450,673

According to the above statement the earnings on subsidiary securities increased $131,807 during the year, while miscellaneous earnings increased $38,296, or a gross increase of $170,103. Expenses and taxes rose $17,454, and interest charges $63,621, so the net income available for depreciation and dividends increased only $89,028. The dividends on the first preferred stock were increased $95,626, and those on the second preferred stock were decreased $20,364, giving a balance increase for the year of $13,767. It should be noted that the earnings given for the year ended June 30, 1914, are exclusive of $34,483 representing suspended earnings pending rate adjustments in progress. The addition of this item gives a total balance for the year of $48,250.

The comparative consolidated income statement of the subsidiaries for the twelve months ended June 30, 1913 and 1914, follows:

	1914	1913
Gross earnings	$6,199,421	$5,712,538
*Operating expenses, etc. (includes maintenance and federal income tax)	3,817,070	3,363,564
Net earnings	$2,382,351	$2,348,974

---

*Operating expenses for 1914 as compared to 1913 include increased charges for maintenance reserves, general taxes and federal income tax.

AUGUSTA-AIKEN DIVIDEND SUSPENSION

The regular quarterly dividend of 1½ per cent on the cumulative preferred stock of the Augusta-Aiken Railway & Electric Corporation, Augusta, Ga., will not be paid on Oct. 1. The directors have issued to stockholders a letter reading in part as follows:

"During the first six months of the current year the company's earnings showed a surplus of $61,170, an increase of $10,008, or 19.7 per cent, over that of the corresponding period of 1913. Careful estimates for the last six months of 1914 indicate a surplus of $25,000. The total surplus for the year, therefore, is expected to be about $90,000, which is the amount of the annual dividend on the preferred stock. It is estimated that the net earnings for the last six months of 1914 will be more by approximately $38,000 than for the corresponding period of 1913, but the surplus will decrease about $40,000. This decrease is caused by additional taxes and fixed charges of $78,612, owing to the taking over of the new hydroelectric plant of the Georgia-Carolina Power Company on the Savannah River.

"During the first six months of this year the company has expended for extensions and betterments $51,404, and further expenditures for the same purpose will be necessary during the last six months of this year. Ordinarily these would be in large part financed by the sale of bonds, but financial conditions render this impossible at present. For these reasons and because of the general disorganization occasioned by the unexpected outbreak of the war in Europe, the directors consider it necessary to suspend payments of preferred stock dividends until they can be resumed without weakening the company's cash position. In the judgment of the directors the expected development is only deferred, and it is only a question of time when the additional business will be secured for which the large investment in the new hydroelectric plant and other new business extensions was made."

RAILWAY FINANCES IN BIRMINGHAM

In connection with the default of interest on the first mortgage bonds of the Bessemer, Ensley & Birmingham Railroad, Birmingham, Ala., Sept. 1, as noted in the ELECTRIC RAILWAY JOURNAL of Sept. 12, an independent bondholders' protective committee has been formed, consisting of S. H. Cunningham, Boston; Oscar Dare, Philadelphia; Boyd McDowell, Elmira, N. Y.; J. N. H. Campbell, Hartford, Conn., and George T. Wood, Louisville, Ky. The new committee requests bondholders to make no deposits until a complete examination of books and finances has been made by its accountants and engineers. The examination was begun in Philadelphia and Birmingham on Sept. 14.

A receiver for the company, General Superintendent I. W. Ross, was appointed on Sept. 1. Mr. Ross has issued a statement in part as follows:

"The service will continue without interruption and every effort will be made to take care of the patrons of the line. The impossibility of completing the system and making necessary extensions which became certain in the spring, has made the reorganization of the property inevitable. The average passenger haul is in excess of 6 miles per passenger, and while the public has patronized the line liberally it has become more and more evident that the construction of laterals and extensions would be necessary to increase the revenue of the line sufficiently to take care of the high cost and long mileage haul of the trunk line. A complete financial statement brought down to Sept. 1 will be finished by the auditors immediately and made available to all parties interested. The company has taken care of all liquidated and undisputed liabilities outstanding to Sept. 1."

Babylon (N. Y.) Railroad.—The Babylon Railroad has been granted an extension of time in which to pay creditors' claims now outstanding. This road is in the hands of Receiver R. J. Hawkins. In denying the application to sell the road at public auction to settle the claims against it, Judge Chatfield made the following comment: "On the basis of statements made and the offer of the River Holding Company to pay one-half of the merchandise creditors by Oct. 16 in case the road should not be sold at that time and to present a proposition for the payment of the balance, the court will make no order to sell unless on further application before Oct. 16."

Boston Suburban Electric Companies, Newtonville, Mass.—Charles W. Leonard has been elected as trustee of the Boston Suburban Electric Companies to succeed Frank A. Day, deceased.

Brazilian Light & Traction Company, Toronto, Ont.—The directors of the Brazilian Light & Traction Company have declared a dividend of 1½ per cent on the issue of ordinary capital stock. A circular issued to the shareholders states that there is not the least foundation for uneasiness with reference to the company's affairs in South America. The company controls the Sao Paulo Tramway, Light & Power Company and the Rio de Janeiro Tramway, Light & Power Company.

Cleveland (Ohio) Railway.—The Ohio Public Utilities Commission on Sept. 15 authorized the Cleveland Railway to issue common capital stock amounting to $1,068,500 par value to be sold for not less than par. The application for this stock was noted in the ELECTRIC RAILWAY JOURNAL of Sept. 12. The proceeds are to be used to reimburse the income account for moneys actually expended and to be applied to further payment for the construction of additions, extensions and improvements to the system and the acquisition of additional facilities as follows: Land for stations, terminals and yards, $50,000; shops, stations and other buildings, $542,000; fire protection, $90,000; rolling stock, $665,000; total, $1,347,000. The company is required to report semi-annually on Jan. 15 and July 15 regarding the disposition of the proceeds. It is said that the stock, which is part of the $1,460,000 first offering under the terms of the Taylor grant in 1910, of which only about $400,000 was taken by the stockholders, will not be again offered to the stockholders but will be sold in the open market at a premium or retained in the treasury for use as a basis for collateral loans.

Columbus Railway, Power & Light Company, Columbus, Ohio.—On Sept. 10 the directors of the Columbus Railway, Power & Light Company declared the regular quarterly dividend of 1½ per cent on the preferred stock, series A, payable on Oct. 1. The directors took no action toward financing proposed improvements. It is said, however, that improvements and extensions which are urgent will be financed out of earnings.

The Columbus, Urbana & Western Electric Railway, Columbus, Ohio.—Judge E. B. Kinkead on Sept. 5 granted permission to L. P. Stevens, receiver of the Columbus, Urbana & Western Electric Railway, to file his final accounting and terminate the receivership. Mr. Stevens stated in his application that the $438,000 of outstanding bonds of the company are held by the Columbus Railway & Light Company. The property, which embraces 7½ miles of track, went under receivership early in 1912.

Elmira Water, Light & Railroad Company, Elmira, N. Y.—The final step in the absorption of the West Side Railroad of Elmira by the Elmira Water, Light & Railroad Company has been authorized by the Public Service Commission for the Second District of New York. The latter company at present owns all the capital stock of the former and leases its plant and equipment. The commission has now authorized the West Side Railroad to transfer to the controlling company all its railroad, equipment, property, rights, system and franchises for the consideration of $1 and the acceptance of the mortgages now existing on the property.

Kingston (N. Y.) Consolidated Railroad.—A dividend of 3 per cent was paid on Sept. 1 on the $200,000 of the 4 per cent cumulative preferred stock of the Kingston Consolidated Railroad. This was the first distribution since Jan. 1, 1911, when 4 per cent was paid. The full rate of 4 per cent was paid from the consolidation with the Colonial City Traction Company in December, 1901, until August, 1908.

Manaos Tramways & Light Company, Manaos, Brazil.—At a recent meeting of the Manaos Tramways & Light Company held in London, it was stated that finance and commerce are now disorganized and the future of the companies seems somewhat obscure. The efforts to collect the state debt for public lighting had not met with any success. The accounts for the last fiscal year showed tramway receipts of £87,029, as compared to £106,148 for the previous year, a decrease of £19,119. The lighting receipts increased from £44,148 to £44,395, giving a decrease in the gross income from £151,741 to £132,877. The total operating expenses decreased from £101,942 to £96,848, and the net surplus decreased from £28,107 to £14,426, or more than 48 per cent. The transferal of £8,000 to the contingencies and accident reserve account and of £6,000 to the renewals reserve was recommended, the balance of £3,861 being carried forward to surplus.

Milwaukee Electric Railway & Light Company, Milwaukee, Wis.—The New York Stock Exchange has listed $1,305,000 of general and refunding mortgage 5 per cent bonds, due 1951, of The Milwaukee Electric Railway & Light Company. The Exchange has also authorized an additional $695,000 of these bonds to be listed on notice that they have been sold, making the total amount to be listed $2,000,000. The total expenditures on account of which the bonds listed have been used amounted to $2,281,625, from which was deducted $177,309 for property scrapped, displaced, sold, etc. Expenditures were divided as follows: Roadway and track, $322,617; electric transmission and distributing system, $434,152; building and improvements, $259,455; transformers, motors, lamps, etc., $246,454; miscellaneous, $191,222; power plant equipment, $403,749, and cars and electrical equipment of cars, $423,976.

New York (N. Y.) Railways.—A board of arbitration composed of H. H. Porter, James Marwick and W. G. Ross has been appointed to decide upon the rate of interest that is to be paid on the adjustment income bonds of the New York Railways for the six months ended June 30 last. The directors of the company at a meeting held recently decided that the rate would be 1.24 per cent for the six months, but as there were only three of the directors representing the bondholders present at the meeting who would sign the authorization, it became necessary to call for a board of adjusters. Mr. Porter and Mr. Marwick were chosen one each by the railway and the trustee of the mortgage and they in turn chose Mr. Ross. Mr. Ross was formerly managing director of the Montreal (Que.) Street Railway, but is now president of the Amalgamated Asbestos Company and chairman of the Montreal Harbor Commission. Mr. Porter is a member of the firm of Sanderson & Porter, and Mr. Marwick is a member of the firm of Marwick, Mitchell & Company.

Ogden (Utah) Rapid Transit Company.—It was recently reported that the stockholders of the Ogden Rapid Transit Company had approved a plan for the amalgamation of the company with the Logan Rapid Transit Company as the Ogden, Logan & Idaho Railway. It is said that the Ogden Rapid Transit Company in organizing the Ogden Logan & Idaho Railway has not yet perfected its plans and no securities have been issued up to the present time. The Ogden Rapid Transit Company operates 50 miles of electric track and 6 miles of steam track, while the Logan Rapid Transit Company, which is controlled by the Ogden Rapid Transit Company, operates 14¼ miles of track.

Portland, Railway, Light & Power Company, Portland, Ore.—The New York Stock Exchange has listed $1,064,000 of additional first and refunding 5 per cent sinking fund mortgage convertible coupon bonds, series A, of the Portland Railway, Light & Power Company. The total amount listed is now $17,064,000.

Reading (Pa.) Transit Company.—The Public Service Commission of Pennsylvania on Sept. 4 approved the transfer and purchase of the Lebanon Electric Light Company by the Reading Transit Company for a consideration of $41,000 in cash and $15,000 in securities. The latter amount represents the actual value of $75,000 of Eastern Light & Power Company stock. The company serves about 500 consumers in the various townships surrounding Lebanon.

San Francisco (Cal.) Municipal Railways.—The Board of Supervisors of San Francisco is in receipt of a communication from City Treasurer John E. McDougald stating that he has disposed of $150,000 of Geary Street Railroad 5 per cent bonds to Bond & Goodwin.

Second Avenue Railroad, New York, N. Y.—On Sept. 10 Judge Lacombe in the United States District Court signed an order allowing claims for $594,727 against the New York City Railway. Of this amount $275,391 is due for a special franchise tax from 1902 to 1906 with interest to Sept. 24, 1907, which it is said should have been paid by the New York City Railway as lessee of the Second Avenue line. The sum of $319,335 is due for damages because of the failure of the lessee to maintain the property in good condition between April, 1902, and October, 1907. The report of Special Master W. L. Turner was confirmed with the above modifications.

United Light & Railways Company, Grand Rapids, Mich.—The directors of the United Light & Railways Company have declared the usual quarterly dividend of 1½ per cent on the first preferred stock and three-quarters of 1 per cent on the second preferred stock, both payable on Oct. 1 to holders of record Sept. 15. No dividend on the common stock, however, is declared at this time. From April, 1913, to July, 1913, 1 per cent was paid quarterly, 1 per cent additional being paid in stock in April, 1914. Frank T. Hulswit, president of the company, says: "We have earned sufficient to pay the dividend on the common stock as we have in the past but prefer to take the conservative course now. We cannot say when the next common dividend will be declared."

West Penn Traction & Water Power Company, Pittsburgh, Pa.—The West Penn Traction Company, the operating subsidiary of the West Penn Traction & Water Power Company, has begun the work of improvements and extensions, to provide for which the company in April, 1914, sold $6,000,000 of notes, as mentioned in the ELECTRIC RAILWAY JOURNAL of May 9, 1914. The cost of carrying out the improvement program for 1914 and 1915 will be not less than $4,000,000, of which $700,000 will be provided out of income and the remainder from the proceeds of the note issue. The notes are secured by a pledge of $1,250 first mortgage 5 per cent bond for each $1,000 note, in addition to other collateral. Of the first mortgage bonds there are $5,465,500 outstanding, secured by a first lien on 38.89 miles of electric railway, 133 miles of single-circuit and 26 miles of double-circuit transmission line, thirteen substations, five steam-power generating stations and other property.

Youngstown & Sharon Street Railway, Youngstown, Ohio.—Formal protest has been lodged with the Public Utilities Commission of Ohio by the Youngstown & Sharon Street Railway against granting the application of the Mahoning County Electric Light Company for permission to issue $1,000,000 of capital stock. The former company is seeking to prevent competition from the Mahoning company at Youngstown, on the ground that there is not enough business for two companies.

DIVIDENDS DECLARED

Asheville Power & Light Company, Asheville, N. C., quarterly, 1¾ per cent, preferred.

California Railway & Power Company, San Francisco, Cal., quarterly, 1¾ per cent, prior preferred.

Carolina Light & Power Company, Raleigh, N. C., quarterly, 1¾ per cent, preferred.

Chicago City Railway, Chicago, Ill., quarterly 2½ per cent.

Elmira Water, Light & Railroad Company, Elmira, N. Y., quarterly, 1¾ per cent, first preferred; quarterly, 1¼ per cent, second preferred.

Lake Shore Electric Railway, Cleveland, Ohio, quarterly, 1½ per cent, first preferred.

Lincoln Traction Company, Lincoln, Neb., 1 per cent, common.

Manila Electric Railroad & Light Corporation, Manila, P. I., quarterly, 1¾ per cent.

Northern Ohio Traction & Light Company, Akron, Ohio, quarterly, 1½ per cent, preferred.

United Light & Railways Company, Grand Rapids, Mich., quarterly, 1½ per cent, first preferred; quarterly, three-quarters of 1 per cent, second preferred.

Washington, Baltimore & Annapolis Electric Railroad, Baltimore, Md., quarterly, 1½ per cent, preferred.

West End Street Railway, Boston, Mass., $1.75, common.

Traffic and Transportation

MIDDLESEX & BOSTON FARE HEARINGS

Company Requests 6-Cent Fares With 1 Cent More for Transfers—Increase Required by Greater Expenses and Reserve for Depreciation

The Massachusetts Public Service Commission is hearing the petition of the Middlesex & Boston Street Railway for authority to increase the fare unit on its entire system to 6 cents and to 7 cents for a ride including a transfer. The petition is opposed by residents of the municipalities served by the company. The road is largely a country property and extends through Newton and Waltham to Watertown, thence to Wellesley, Natick, Framingham and Hopkinton to Westboro. Nine different companies were consolidated into a single property. The total population tributary to the lines is 175,000. About 130 miles of track are operated.

The fare was originally 5 cents, but was increased to 6 cents in 1908 on portions of the system west of Newton Lower Falls and on the Lexington & Boston division. In Newton and Waltham the fare was left at 5 cents except on part of the old Newton & Boston system. A charge of 1 cent was made, however, in that district for each transfer. This institution of the 6-cent fare was covered in articles beginning in the ELECTRIC RAILWAY JOURNAL of Nov. 28, 1908, under the caption "Reasons for Increased Fares on Massachusetts Street Railways."

The change proposed essentially means a 6-cent fare applicable in Newton and Waltham, where a 5-cent fare is now paid, and on the route through Wellesley and Natick it involves giving up the present fifty-ride book under which it has been possible to ride for a nickel, and, as stated, imposes an additional charge of 1 cent for a transfer. The company appeals to the commission to grant the increase on the ground that its receipts are inadequate compensation for the service rendered. The petition was prompted by an award of a board of arbitration dated June 22, 1914, which increased the compensation of the men about 15 per cent, as noted in the ELECTRIC RAILWAY JOURNAL June 27, 1914, page 1472. In addition to the increase in wages the company must at once spend money for improvements which cannot be capitalized. The surplus after paying 4 per cent dividends in the last two years totals $1,200. The company has outstanding $1,987,000 of stock, $1,983,000 of bonds and $1,255,000 of notes.

Arthur A. Ballantine, counsel for the company, said that in 1901, before the properties were consolidated, the salaries of general officers and clerks totalled $52,000. For the year ending June 30, 1914, these totalled $16,000, although the traffic handled was much greater. Wages, on the other hand, increased from $150,000 in 1901 to $250,000 for the last year. Receipts per mile are 2 cents less than the average for companies elsewhere in Massachusetts. The total amount of the increase in wages occasioned by the arbitration award in the three-year period to which it applies is about $100,000. Adequate provision for depreciation would require more than $50,000 annually. If no shrinkage in travel occurs as a result of the increase in fares the revenue will be increased by about 106,000 a year.

George M. Cox, general manager, testified that the average cost of permanent property per mile of track is $23,440, compared with $37,294 for the State as a whole; equipment cost per mile is $9,867, against $12,270 on all other roads. The total capital investment per mile on the Middlesex & Boston is $43,265, compared with $68,623 on the Massachusetts lines as a whole. Passenger earnings per car mile on the thinly populated Needham line varied from 6.46 cents in 1904 to 9.28 cents in 1914. On the best lines of the company the earnings rose from 28.54 cents per car mile in 1904 to 32.62 cents in 1914. Gross earnings were 25.76 cents per car mile on the system in 1913, compared with 29.19 cents on all Massachusetts roads. In 1913 the company was operated for 1.56 cents less per car mile than the other roads, and its net earnings were 1.87 cents less. The company's fixed charges increased from $96,356 in 1901 to $201,905, or from 3.2 cents per car mile in 1901 to 5.42 cents in 1914. The company disbursed $29,690 in back pay for the year ending June 30, 1914, as a result of the award. Changes in the schedule resulting from agreement with the men will cost from $8,000 to $12,000 per year, assuming that only six extra crews are required. About $52,500 needs to be expended in rehabilitation. Mr. Cox described the arrangements by which power is purchased by the Middlesex & Boston from the Edison Electric Illuminating Company of Boston and said that the Edison service resulted in better power at less cost than the railway could furnish in its plants. The total power cost of the company is now about $150,000 a year.

Chairman McLeod questioned the retention of the equipment in these old plants as a basis upon which the rate of fare is in part to be figured and the witness rejoined that the possession of these plants serves the company as a possible emergency source of power and may in a measure affect the price offered in future contracts. He said that the absence of a depreciation provision in the past was not culpable, but that in any fare adjudication such an allowance must be made and that the rates must be fixed at such a point as will enable the reserve to be set aside to meet the depreciation that has accrued in the past.

Mr. Cox stated that the average fare received per passenger was 5.07 cents in the fiscal year 1914, including transfers. It is estimated that west of Newton Lower Falls the extension of the 1-cent transfer charge would yield the company $1,570 per year; that the abolition of the fifty-ride books would yield $7,392; that a transfer charge added to the existing 6-cent fare on the Newton and Boston division would yield $2,507; that the same charge on the Lexington and Boston division would yield $2,130, and that the establishment of a 6-cent fare in Newton and Waltham would add $58,719 to the company's income. The total passenger revenue for the fiscal year 1914 was $951,808, and it is estimated that if the proposed changes in rates are granted the income will be increased 12 per cent. Twenty-two per cent of the passengers in the Wellesley-Natick section of the road use the fifty-ride ticket books. The company operated 3,008,000 car miles in 1901 and 3,725,000 car miles in 1913, the number of passengers increasing from 12,000,000 to 19,000,000. Hearings were to be resumed on Sept. 17.

Booklet of Information for Trainmen.—The Holyoke (Mass.) Street Railway issued a twelve-page booklet covering the summer schedule of 1914 which is of particular interest in that it contained information for the guidance of motormen and conductors in running time, meeting and transfer points of cars on all lines, etc.

Peculiar Express Car Accident.—While rounding a sharp curve on the Ohio Electric Railway near West Liberty, Ohio, on Sept. 11, an express car left the track and crashed into a house. Fire started from the overturned stove and both car and house were soon ablaze. The fire was extinguished, however, before the blaze had done much damage.

Rehearing on Rear Platform Guard Order.—The Public Service Commission of the First District of New York has granted an application for a rehearing to be held on Sept. 22 on an order adopted some months ago requiring the New York Consolidated Railroad to maintain a guard on the rear platform of all Brooklyn elevated trains. This order was adopted after evidence had been produced showing that there had been considerable rowdyism.

Handling Express Between St. Thomas and Port Stanley.—The London & Lake Erie Railway & Transportation Company, London, Ont., Can., has arranged with the Canadian Express Company to carry express over the section of its line between St. Thomas and Port Stanley, Ont., and has applied to the St. Thomas City Council for permission to run over the city's line to the Grand Trunk Railway station on Talbot Street, in order to carry out the agreement.

Service on the Wellston & Jackson Belt Line.—The Ohio Public Utilities Commission refused a rehearing on the case of the Hocking Valley Railroad relative to the order of the commission to resume the operation of electric cars on the Wellston & Jackson Belt Line on Sept. 11. The case was at once appealed to the Ohio Supreme Court, on a petition in error. The company asserts that the findings of the commission are unlawful, unreasonable and beyond its jurisdiction in that they will operate to deprive it of its property without compensation and without due process of law. Operation of electric cars was suspended some weeks ago and the commission ordered the company to resume the service by Sept. 15.

New Traffic Regulations for Congested Brooklyn.—Upon recommendation of the Brooklyn committee of public safety and of Leon G. Godley, third deputy police commissioner, Police Commissioner Woods has ordered new traffic regulations in Fulton Street, Brooklyn, between Court Square and Bond Street. Under the new arrangement, vehicles are prohibited from crossing Fulton Street, except at the intersections of streets, between Court Square and Bond Street. The object of the change is to prevent indiscriminate driving back and forth across the street in this congested section of the street, and to avoid chances for collisions between cars and vehicles, collisions between vehicles and the pillars of the elevated railroad, and injury of pedestrians.

Combined Railway and Ferry Fare in Effect.—The new arrangement between New York City and the New York Railways has gone into effect whereby for a 5-cent fare northbound transfers will be issued by the municipal ferry at the Battery, New York, good for a continuous ride on the ferry from St. George, Staten Island, and from South Ferry, Manhattan, on the Broadway, Columbus, Sixth, Eighth and Amsterdam Avenue surface lines. Southbound conductors on the cars of these lines issue transfers to ferry boats to St. George. Under the contract between the city and the railway the former will receive 2 cents and the latter 3 cents of the 5-cent fare. This arrangement is in accordance with an agreement reached in connection with the new subway operating contracts, but as it was impracticable to embody this agreement in the dual system contracts a separate contract was prepared.

Electric Line Declines Offer to Join in Rate Application.—J. R. Harrigan, general manager of the Kansas City, Clay County & St. Joseph Railway, was invited to join the steam railroads of Missouri in filing with the Public Service Commission on Sept. 15 new passenger tariffs based on the 3 cents per mile which recent decisions have convinced the railroads that they have a chance of establishing. Mr. Harrigan declined to join. Negotiations are now pending between the Quincy, Omaha & Kansas City Railroad and the Kansas City, Clay County & St. Joseph Railway for the handling of the steam road's passenger service into Kansas City by the electric railway. It is said that the Quincy, Omaha & Kansas City Railroad is seeking a way to avoid entering the new union station, and arrangements for handling its traffic into and through Kansas City after Jan. 1 must be made soon. The steam road has its station at Avondale within a few feet of the electric line station. Avondale is about 5½ miles from the electric line's Kansas City station, and the first station on the Excelsior Springs division north of North Kansas City. The Quincy, Omaha & Kansas City Railroad runs between Kansas City and Quincy, Ill.

Co-operation Among Farmers Urged.—Farmers' co-operative societies, either for buying or for selling, are very much favored by Richard H. Wyatt, general freight and passenger agent of the lines of the Louisville & Interurban Railway and the Louisville & Eastern Railway. In his efforts to increase the amount of freight handled on these lines he urges co-operation among the farmers in the communities along the routes. According to Mr. Wyatt, the larger part of the in-bound business of the lines originates on the farms. As the farmer has found that it is greatly to his advantage to market his produce in person, he hauls it in by wagon. With an organization, however, he would be able to make advantageous marketing arrangements and could ship confidently and in large quantities. One of the successful organizations of the kind on the route of the lines Mr. Wyatt supervises is at Middletown, Ky., 15 miles east of Louisville. This organization has been in existence for three years and has been fostered by Mr. Wyatt, with a consequence that during the berry season the Louisville & Eastern Railway gets many a ton of high-class and profitable freight. This organization is cited to the farmers on whom he urges the formation of similar organizations as a sample of what might be done. In St. Matthews, also east of Louisville, the farmers have organized, while across the river in the vicinity of New Albany the Insull electric lines have taken away from the steam roads a very large proportion of the fruit business of the several fruit growers' organizations in that locality.

Personal Mention

Mr. W. H. Gardner has resigned as chief statistician of the Doherty Operating Company, New York, N. Y.

Mr. Frank L. Blackburn has been appointed chief statistician of the Doherty Operating Company, New York, N. Y., succeeding Mr. W. H. Gardner, recently resigned.

Mr. A. L. Adams, formerly with the Tacoma Railway & Power Company, Tacoma, Wash., is now connected with the Savannah (Ga.) Electric Company as assistant transportation superintendent.

Mr. W. B. Voth, who has been superintendent of light and power of the Sheboygan Railway & Electric Company, Sheboygan, Wis., for ten years, has been appointed chief engineer of the Empire United Railways, with headquarters at Syracuse, N. Y.

Mr. W. J. Gough has been elected vice-president and superintendent of the Los Angeles & San Diego Beach Railway, San Diego, Cal., succeeding Mr. R. B. Talbot, who has resigned to engage in other business. Mr. Gough is also acting as chief engineer of the company, which has under way the electrification of its line between San Diego and La Jolla.

Mr. Frederick C. Noble, division engineer of the Public Service Commission for the First District of New York in charge of subway construction in Brooklyn, has resigned, and will enter private practice. Mr. Noble was born in Michigan in 1872 and was graduated in civil engineering from the University of Michigan in 1894. He has been connected with the Public Service Commission and its predecessor, the Rapid Transit Commission, since 1900, being appointed division engineer in 1905.

Mr. J. H. Sanford has been appointed purchasing agent of the Connecticut Company, with headquarters in New Haven, Conn., reporting to Mr. L. S. Storrs, president. Mr. Sanford's jurisdiction will also include the Housatonic Power Company, Berkshire Street Railway, New York & Stamford Railway, Westchester Street Railroad and the Westport Water Company. He has also been appointed purchasing agent of the Rhode Island Company, Providence, R. I., reporting to Mr. A. E. Potter, president.

Mr. Frank Wert has been engaged by the Mahoning & Shenango Railway & Light Company, Youngstown, Ohio, to have charge of its department of public relations, with the title manager of public relations. In this position Mr. Wert will take over some of the work which fell previously to the lot of Mr. H. B. Manington, whose activities as assistant to the president necessitate his frequent absence from Youngstown. Mr. Wert was formerly connected with newspapers in Philadelphia, Baltimore and Harrisburg.

Mr. Paul C. Alford, chief clerk of the Piedmont & Northern Railway, has been appointed agent of the commercial office of the company with headquarters at Spartanburg, S. C. Since the opening of the Piedmont & Northern Railway between Anderson and Greenwood, Mr. Alford has acted as chief clerk to Mr. C. S. Allen, Jr. He had several years' experience in both the transportation and the traffic departments of the Southern Railway and the Seaboard Air Line in Atlanta. Mr. Alford resigned as chief rate clerk in the office of the assistant general freight agent of the latter company to become connected with the Piedmont & Northern Railway.

Mr. George A. Lewis has been appointed local manager of the Auburn & Syracuse Electric Railroad, which is included in the system of the Empire United Railways, Syracuse, N. Y. He will have charge of the operation of cars and also of track, carhouses, substations and everything else pertaining to the road. Mr. Lewis was born in 1876 on a farm in Ontario County, New York, and was educated at the district school in Orleans. Subsequently, he took a two-year commercial course at Elmira, N. Y. His first railroad experience was as timekeeper during the construction of the Rochester & Eastern Railway. When that road was opened for operation he was placed in charge of claims and similar matters. Later he was appointed superintendent of construction of the Milwaukee (Wis.) Northern Railway, serving the same interests that built the Rochester & Eastern Railway. When the Milwaukee Northern Railway was completed and placed in operation Mr. Lewis was made general agent of the company and later was appointed superintendent of operation.

Mr. Charles Craigmile, who has been assistant superintendent of the Lake Shore division of the Empire United Railways, Syracuse, N. Y., has been appointed local manager of the Syracuse & South Bay Electric Railroad, the Brewerton line and the Sagamore Navigation Company. He will also have charge of land and islands owned by the companies at South Bay and Oneida Lake. The appointment becomes effective on Oct. 1. Mr. Craigmile and all other employees on the lines will have headquarters at North Syracuse, where administration offices are being fitted up in the carhouse. This will make the Syracuse & South Bay road an independently operated company, subject, however, to direction from the office of Mr. Ernest Gonzenbach, the general manager of the Empire United Railways. Mr. Craigmile was born in Illinois twenty-nine years ago and was educated at Farnhamville, Ia. His first railroad experience was as a telegrapher on the Chicago & Northwestern Railroad. Later he was made station agent at different points of that line. While acting as station agent at Cleveland, Wis., he received an offer to be dispatcher of the Sheboygan Railway & Electric Company, Sheboygan, Wis. Last April he was appointed assistant superintendent of the Lake Shore & Northern Division of the Empire United Railways.

Mr. W. F. Raber, vice-president and general manager of the Arkansas Valley Railway, Light & Power Company, Pueblo, Col., has been elected president of the Colorado Electric Light, Power & Railway Association. Mr. Raber is a native of Ohio. He entered business with the Bell Telephone Company about twenty-five years ago, but soon took up street railway and electric light work. He managed lighting plants for some time and finally became general manager of the Mansfield Railway, Light & Power Company, Mansfield, Ohio. He next became connected with H. M. Byllesby & Company, Chicago, and served them for some time as manager of electric light, power and gas plants in Oklahoma. In 1906 he was appointed by Byllesby & Company as manager of the Ottumwa Railway & Light Company, Ottumwa, Ia., in which capacity he continued until 1911. He was then appointed general manager of the Pueblo & Suburban Traction Company, a Byllesby property, since succeeded by the Arkansas Valley Railway, Light & Power Company. The company at Pueblo controls 35 miles of electric railway and does a general lighting business.

W. F. Raber

OBITUARY

Henry M. Goll, one of the pioneers in the traction history of Chicago, died on Sept. 13 at the University Hospital in that city. Mr. Goll settled in Chicago in 1852 and became interested in one of the bus lines which plied on West Twelfth Street between Wentworth Avenue and Ashland Boulevard. Subsequently he was identified with the promotion and construction of the original street railway on Halsted Street.

William A. Stern, senior member of the firm of Stern & Silverman, Philadelphia, Pa., is dead. Mr. Stern was president and a director of the Atlantic City & Shore Railroad, treasurer and director of the Central Passenger Railway, Atlantic City, N. J., treasurer and director of the Atlantic City Construction Company, and president and director of the Philadelphia (Pa.) Railways, the successor to the Southwestern Street Railway. The firm of which he was a member owns a franchise for the construction of a tunnel under the Delaware River between Camden and Philadelphia. Mr. Stern was fifty-four years old. He is survived by a widow and three children.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

Miami (Fla.) Traction Company.—Application for a charter has been made by this company in Florida to build an electric railway in Miami. Capital stock, $500,000. Officers: B. B. Tatum, president; J. H. Tatum, vice-president; J. R. Tatum, secretary, and S. M. Tatum, treasurer. [E. R. J., Aug. 29, '14.]

***Carolina Central Electric Railway, Florence, Ga.**—Incorporated in Georgia to build an electric railway in Florence. Capital stock, $5,000.

***Marble Creek Valley Railway, St. Maries, Idaho.**—Incorporated in Idaho to build an electric or steam railway from Clarpia to Pocono, 20 miles, and a line from the mouth of Buzwell Creek to Pierce City, 25 miles. Capital stock, $100,000. Frederick Herrick, Lac du Flambeau, Wis., is reported interested.

Joliet & Eastern Traction Company, Chicago, Ill.—Incorporated in Illinois to build an electric railway to connect Joliet, New Lennox, Frankfort, Matteson, Chicago Heights, Hammond and Chicago. Headquarters: Chicago. Capital stock, $1,000. The first board of directors is composed of Edmund J. Clausen, Irving J. Solomon, David F. Rosenthal, Leo S. Kosetcheck and Jacob Schwartz.

***East Village & Harbor Traction Company, Ashtabula, Ohio.**—Incorporated in Ohio to build electric railways to encircle the city of Ashtabula, ending at the Harbor. Capital stock, $10,000. Incorporators: Mark E. Copeland, Cleveland; C. Verbsky, M. Burge, W. S. Mitchell and others.

FRANCHISES

Los Angeles, Cal.—The Board of Public Utilities recently has recommended to the City Council that the application of the Pacific Electric Company for a twenty-one-year franchise to operate the outside tracks of its four-track system across certain public highways on its Long Beach line between Ninth Street and Slauson Avenue in Los Angeles be granted.

Los Angeles, Cal.—The Los Angeles Railway has received a ninety-day extension of time on its franchise in which to complete its Vernon Avenue crosstown line in Los Angeles.

New Haven, Conn.—The Connecticut Company has asked the Public Utilities Commission for approval of the method of reconstruction of double tracks in Church Street in New Haven.

Aurora, Ill.—The Aurora & Mendota Electric Railway will shortly ask the Council for a right-of-way in Aurora. The new line is to extend from Aurora through Yorkville, Plano and Sandwich to Mendota.

Lafayette, Ind.—The Lafayette & Northwestern Railroad has received a franchise from the County Commissioner to build its line through Benton County. This line will connect Lafayette and Chicago.

Muskegon, Mich.—The Muskegon Traction & Lighting Company will ask the Council for a franchise for an extension of its Allen Street line in Muskegon.

Collingswood, N. J.—The Public Service Railway has asked the Council for a franchise to make changes in its tracks through West Collingswood to shorten the line to Clementon.

Islip, N. Y.—The Suffolk Traction Company has received a year's extension of time on its franchise in which to extend its lines to West Sayville.

Westfield, N. Y.—The Jamestown, Westfield & Northwestern Railroad has asked the Council for a franchise to extend its line on the east side of South Portage Street, in Westfield, from Martin-Wright Road to Campbell Street, where the line will connect with the Chautauqua Traction Company's line.

London, Ont.—The London Street Railway has asked the Council for an extension of time on its franchise in which to complete its line on Wharncliffe Road in London.

Portland, Ore.—The Portland & Oregon City Railway has received a twenty-five-year franchise from the Council in Portland. Work is to be begun on the line within the city limits within sixty days. Other franchises are now pending to allow the company the use of the east side and the northeast section of the city of Portland.

Lynden, Wash.—The Blaine-Lynden Electric Railway has received a franchise from the Council in Lynden. The Council of Blaine has already granted the company a franchise over certain streets and a large terminal tract on the waterfront in Blaine. A greater part of the right-of-way between Lynden and Blaine has been secured and the preliminary work on the line will be done this fall. [E. R. J., Aug. 8, '14.]

Olympia, Wash.—The City Council at an early meeting will ask the Olympia Light & Power Company to extend its line from the present terminus on Fourth Street to the city limits of Olympia.

TRACK AND ROADWAY

***Los Angeles, Cal.**—Plans are being considered to build a crosstown electric railway from First Street and Evergreen Avenue, north on Evergreen Avenue to Wabash Avenue in Los Angeles. The Malabar Improvements Association and the residents of Boyle Heights are interested.

Connecticut Company, New Haven, Conn. — Plans are being made by this company to reconstruct and extend a number of its lines within the next few months.

Waterbury & Milldale Tramway, Waterbury, Conn.—Arrangements are being made by this company to begin work on the 3 miles of new track in Southington as soon as the company receives authority from the Public Utilities Commission for the construction of the line.

Jacksonville (Fla.) Traction Company.—Additional track on Hogan Street from Bay Street to Eagle Street, Cedar Street and Pearl Street in Jacksonville will soon be built by this company.

Miami (Fla.) Traction Company.—Bids are being asked by this company for the construction of its line on Avenue C between Tenth Street and Waddell Street in Miami, L. D. Llewellyn, 1107 Avenue C, Miami, chief engineer. [E. R. J., Aug. 29, '14.]

Waycross Street & Suburban Railway, Waycross, Ga.—Right-of-way has been secured and arrangements for the necessary material have been made by this company for its extension to Hebardville, a suburb just beyond the northern city limits of Waycross.

Twin Falls (Idaho) Railroad.—This company has placed in operation its extended line between Twin Falls and Shoshone Falls. Electric storage battery cars are operated.

Evansville & New Harmony Traction Company, Evansville, Ind.—Surveys have been completed by this company on its line between Evansville and New Harmony. [E. R. J., Aug. 15, '14.]

Evansville & Eastern Electric Railway, Evansville, Ind.—Plans have been contemplated by this company to extend its line from Henderson to Owensboro, Ky.

Richmond-Hamilton Traction Company, Richmond, Ind.—Plans are under consideration to build an electric railway from Hamilton, Ohio, to Richmond, Ind. [E. R. J., Aug. 15, '14.]

Orleans-Kenner Electric Railway, New Orleans, La.—This company has increased its capital stock to $3,000,000. Grading has been completed and, except for short gaps, the tracks have been laid from the protection levee, at Claiborne Avenue, in New Orleans to 1 mile beyond Shrewsbury, and from Kenner nearly to Harrahan. Arrangements have been made to operate the interurban cars into New Orleans as soon as the line in Jefferson parish is completed. The contract for this has been signed for some time. Construction of the trestle work across the Illinois Central yards will be begun soon. Henry K. Johnson, chief engineer. [E. R. J., July 18, '14.]

Winnipeg, Selkirk & Lake Winnipeg Railway, Winnipeg, Man.—A report on the condition of this railway, by B. S. Mackenzie, consulting engineer, has been laid before the Manitoba Public Utilities Commission. The report suggests that considerable improvement to the roadbed is necessary to bring it up to a proper condition, and points out that satisfactory progress is being made upon work for the betterment of the line.

Frederick & Brunswick Railway, Frederick, Md.—Preliminary arrangements are being made by this company to begin the construction of the 9-mile railway between Frederick and Brunswick on Nov. 1. Thomas H. Haller, Frederick is interested. [E. R. J., Aug. 29, '14.]

Northern Massachusetts Street Railway, Athol, Mass.—This company is asked to consider plans to extend its line between Winchendon and Winchendon Springs.

Laurel Light & Railway Company, Ellisville, Miss.—Another mile of electric railway has been placed in operation by this company. It extends to the new plant of the Wausau Southern Lumber Company in North Laurel.

Public Service Railway, Newark, N. J.—It is reported that this company plans to build an extension along the old Peapack Railroad bed from Newark, to join the spur of the Rahway Valley Railroad extended from Kenilworth to Morris Avenue.

New York, N. Y.—Bids are desired until Oct. 6 by Public Service Commission, 154 Nassau Street, New York, N. Y., for constructing Section 1 of Route 43, and Section 1 of Route 26, being the diagonal connection under Forty-second Street between the existing subway and the Lexington Avenue subway.

***Blenheim, Ont.**—An organization has been formed to inquire into the construction of a hydro-radial railway from St. Thomas to Amherstburg. A report will be asked from the Ontario Hydro-Electric Power Commission.

Brantford, Ont.—The City of Brantford has taken over the Brantford Street Railway and the Grand Valley Railway and is now in full charge of their operation. An announcement has been made by the Brantford Street Railway Commission stating that there will be no extension work on the Brantford Street Railway and the Grand Valley Railway during the fall and winter.

Port Arthur, Ont.—The ratepayers of Port Arthur have sanctioned six by-laws, which include: an issue of debentures for $12,000 for a double track "Y" at Arthur Street and Cumberland Street in Port Arthur; $2,600 to construct a side track on the Arthur Street line and $26,000 for the purchase of a right-of-way for the southern loop of the belt line in Port Arthur.

West Side Electric Street Railway, Charleroi, Pa.—This company placed in operation on Aug. 19 its 11-mile railway between Charleroi, Bentleyville and Ellsworth.

Du Bois (Pa.) Traction Company.—It is stated that the Jefferson Coal Company plans to build an electric railway from Coal Glen to Falls Creek, to connect at that point with the Du Bois Traction Company's lines.

Schuylkill County Railway, Girardville, Pa.—The new line between Shenandoah and Frackville along the Broad Mountain from Gilberton in the Mahanoy Valley has been placed in operation by this company.

Conestoga Traction Company, Lancaster, Pa.—This company is asked to consider plans to extend its Marietta line from Centre Square, Lancaster, to Maytown.

West Penn Railway, Pittsburgh, Pa.—This company has completed its line between Uniontown, Connellsville and Phillips and will soon place it in operation.

York (Pa.) Railways.—This company has placed in operation its new line which extends from the present terminus on Jackson Street to Virginia Avenue, then south to the Country Club road in York.

Ogden (Utah) Rapid Transit Company.—Work on the Logan extension will be completed within the next two weeks. The company is building extensions both ways from Logan, and the line extending from Wellsville on the south to Lewiston on the north will be in operation by Dec. 15.

Danville Traction & Power Company, Danville, Va.—Work will be begun at once by this company on an extension from its terminus on Lee Street to Berryman Avenue, Cabell Street, Lynn Street and Deboe Street to the railroad station on Craghead Street in Danville. J. F. Rison, president.

Olympia Light & Power Company, Olympia, Wash.—This company is asked to consider plans to extend its line from the present terminus on East Fourth Street to the city limits of Olympia.

Seattle, Wash.—Councilman Erickson, chairman of the City Utilities Committee of the Council, is making plans for the extension of the municipal railway in Seattle, Division "A," into Ballard, following the completion of the new bridge to span the Lake Washington canal at Fifteenth Avenue Northwest. The plan includes the purchase of the Loyal Heights line, operated by Harry Whitney Treat. Mr. Erickson proposes that the Division "A" line cross the Ballard bridge from Nickerson Avenue, follow Leary Avenue to Market Street, and continue on Market Street under a Treat franchise that has never been used to Twenty-eighth Avenue Northwest, and up Twenty-eighth Avenue to the city limits. The tracks now used by the Loyal Heights line on West Sixty-seventh Street and Twentieth Avenue Northwest can be taken up and laid on Twenty-eighth Avenue between West Sixty-seventh and Market Streets in Seattle.

Charleston, Parkersburg & Northern Railroad, Parkersburg, W. Va.—Contracts will be awarded this fall by this company to build part of its 75-mile electric line between Parkersburg and Charleston, via Ripley, Sissonville, Guthrie and intermediate towns. K. B. Stephenson, Parkersburg, secretary. [E. R. J., Dec. 13, '13.]

Monongahela Valley Traction Company, Fairmont, W. Va.—Right-of-way has been purchased by this company for an extension to Riversville.

SHOPS AND BUILDINGS

Savannah (Ga.) Electric Company.—This company is rebuilding its carhouse in Savannah.

Fort Wayne & Northern Indiana Traction Company, Fort Wayne, Ind.—This company announces that its new freight station at Bluffton has been opened.

Cleveland (Ohio) Railway.—This company has received the approval of the City Council for the expenditure of $128,000 for the construction of a new carhouse on Superior Avenue in Cleveland.

Wheeling (W. Va.) Traction Company.—Work has been begun on an addition to this company's carhouse at McMechen. R. G. Byrum's Sons & Company, Wheeling, have the contract for the construction of the building.

POWER HOUSES AND SUBSTATIONS

People's Railway, Wilmington, Del.—This company's auxiliary power house at Brandywine Springs Park was destroyed by fire on Sept. 14. The loss is estimated to be about $20,000.

Moncton Tramways, Electricity & Gas Company, Ltd., Moncton, N. B.—This company is installing at its power plant in Moncton three 200-hp boilers of high pressure, to replace four low-pressure boilers. A portion of the plant is already equipped with high-pressure boilers, and when the present installation is completed the entire plant will be so operated.

Public Service Railway, Newark, N. J.—Extensive alterations are being planned by this company for its power house at Lakeside Avenue in Newark. All generating machinery has been removed from the building, and the section where the boilers were located will be used as a storage house. The improvements, which will include new doors and windows, will cost about $6,000.

Mahoning & Shenango Railway & Light Company, Youngstown, Ohio.—Improvements will be made at once by this company at its Lowellville power house, and new equipment will be added to take the place of that recently destroyed by fire. Instead of rebuilding the separate substations, the company will install a new permanent substation at Lowellville and increase the rating of the plant. A large amount of machinery has already been delivered to the company.

Monongahela Valley Traction Company, Fairmont, W. Va.—The contract for the concrete piles in the foundation of this company's new power plant has been awarded to the Raymond Concrete Pile Company, 140 Cedar Street, New York City, N. Y. The Nicola Building Company is the general contractor.

Manufactures and Supplies

ROLLING STOCK

Empire United Railways, Syracuse, N. Y., noted in the ELECTRIC RAILWAY JOURNAL of Aug. 15 as having ordered twelve semi-steel prepayment passenger cars from the St. Louis Car Company, has specified the following details for this equipment:

Seating capacity	40
Weight (car body only)	15,500 tons
Length of body	26 ft. 6 in.
Length over vestibule	37 ft. 6 in.
Width of sills	8 ft. 2 in.
Width over all	8 ft. 6 in.
Body	semi-steel
Interior trim	mahogany
Headlining	Agasote
Underframe	steel
Roof	arch
Air brakes	G. E.
Bumpers	Hedley
Cables	in conduit
Car trimmings	St. Louis
Control	type K
Couplers	St. Louis, radiating
Curtain fixtures	Cur. Sup. Co.
Curtain material	Pantasote
Destination signs	Hunter
Door signals	Consol.
Fare boxes	Johnson
Fenders	Providence
Gongs	St. Louis
Hand brakes	St. Louis
Headlights	Golden Glow
Motors	G. E.
Registers	Int. R 5
Sanders	air
Sash fixtures	O. M. Edwards
Seats	St. Louis rattan
Step treads	Universal
Trolley catchers	Keystone
Trolley base	G. E.
Trucks	Baldwin
Ventilators	St. Louis

TRADE NOTES

McQuay-Norris Manufacturing Company, St. Louis, Mo., announces its removal to 2008-2010-2012 Locust Street, the location of its new factory.

Willard Doud announces the opening of offices at 538 South Dearborn Street, Chicago, for the handling of all matters pertaining to shop and factory design, construction, equipment and operation.

Asbestos Protected Metal Company, Beaver Falls, Pa., has established a new selling agency in the Chamber of Commerce Building at Detroit, Mich. James E. Walsh has been placed in charge.

Fonger Fender Company, Chicago, Ill., has received orders to equip with tip-tilting automatic fenders the entire system of the Great Falls (Mont.) Street Railway and the Union Electric Company, Dubuque, Ia.

Charles E. Young, formerly a director and advertising manager of the Ohio Brass Company, Mansfield, Ohio, has resigned and has opened an office, with H. W. Young, in the First National Bank Building, Chicago, to give technical advertising service. Mr. Young was a member of the class of 1901, Washington and Jefferson College. After leaving college he was employed first in the advertising department of the Western Electric Company and later in a similar capacity by Porter & Berg (Electric Service Supplies Company). For the last ten years he has been in charge of the advertising department of the Ohio Brass Company.

Esterline Company, Indianapolis, Ind., reports the sale of "Golden Glow" headlights to the following companies during the month of August: Tri-City Railway, Davenport, Ia.; Alton, Jacksonville & Peoria Railway, Alton, Ill.; Public Service Railway, Camden, N. J.; Seattle (Wash.) Municipal Railway; Savannah (Ga.) Electric Company; Elmira (N. Y.) Water, Light & Railroad Company; Springfield (Mass.) Street Railway; Muskegon (Mich.) Traction & Light Company; Detroit (Mich.) United Railway; Southern Traction Company, Dallas, Tex.; Windsor, Essex & Lake Shore Railway, Kingsville, Ont.; Des Moines (Ia.) City Railway; Aurora, Elgin & Chicago Railway, Wheaton, Ill.; Clinton (Ia.) Street Railway; Baldwin Locomotive Works, Philadelphia, Pa.; Galveston (Tex.) Electric Company; Jackson (Tenn.) Railway & Light Company.

ADVERTISING LITERATURE

Ohmer Fare Register Company, Dayton, Ohio, has issued a folder outlining its system for attaining competitive efficiency in fare collecting by means of its monthly merit record bulletin.

Universal Handhole Scraper Company, Chicago, Ill., has issued a folder describing and explaining the operation of its handhole scrapers and handhole plate scrapers for all types of water tube boilers.

American Railway Supply Company, Chicago, Ill., has issued a catalog which describes the Parrigin rail-joint base plate, a device for strengthening the angle-bar rail joint. The construction of the base plate consists of only one piece of modified section of channel, the center portions of the sides of the plates being depressed to form a short truss between supports. The catalog contains views showing the application and installation of the base plate and explains its joint action with the rail joint.

National Tube Company, Pittsburgh, Pa., has issued "National" Bulletin 9-C, which contains a description of several special tests made on Kewanee unions, including the following: expansion test, with tabulated details; air test under water, to which every individual union is subjected before leaving the factory, with illustrations; service test of unions, including illustrations of two unions which were disconnected and reconnected more than 1000 times and which remained tight at the end of each test.

Street Railway Signal Company, Inc., Philadelphia, Pa., has issued a folder describing and illustrating its new type of contactor signal for use with single or double track. These signals, "Model E," are of the all-light trolley-contact operated type, having the three-position aspect for single track opposing protection, but permitting following movements, as recommended by the joint block signal committee of the American Electric Railway Association. The signals may be mounted either on individual iron poles or on existing trolley poles.

Tate, Jones & Company, Inc., Pittsburgh, Pa., have issued a catalog on the subject of their appliances for burning fuel oil in power plants and car shops. The catalog discusses the features of oil as a fuel for furnaces and describes its various types of burners for insuring complete combustion of oil by intimate mixture of air with the fuel. The last part of the catalog describes and illustrates its pumping, heating and regulating systems designed to bring the oil from the tank and furnish it to the burners at the proper pressure and in the right condition.

Prepayment Car Sales Company, New York, N. Y., has issued a folder entitled "Safety Last." The folder points out the neglect of safety, by women who get off slowly moving cars backwards, by men who board fast moving cars and by conductors who are apt to give motormen the bell without seeing whether or not the rear platform is clear. Accidents from these causes often result in payment by the railroad, since juries are prone to overlook the carelessness of the passenger. In this connection prepayment cars, together with the closed door, folding step and door control switch system prevent starting and stopping accidents.

Stone & Webster Construction Company, Boston, Mass., has issued an attractive booklet describing and illustrating, with the aid of a series of large and excellent photographs, the recent completion of the initial development at Big Creek, Cal., for the Pacific Light & Power Corporation, noteworthy because of the unusual natural conditions, engineering problems and commercial accomplishment involved. It is by far the largest high-head development in this country. The most powerful impulse wheels ever built drive the largest electric generators of their type. The transmission line is the longest "express" line in existence and will operate at 150,000 volts, the highest voltage ever used commercially. It carries power 240 miles from a remote spot in the mountains half way between San Francisco and Los Angeles to commercial use in the latter city and adjacent territory. The work included the making of a reservoir 7000 ft. above the sea, the erection of four concrete dams, the construction of two power houses and a substation, the boring of five miles of tunnel through granite, the setting of more than 3000 steel towers over the mountains and across the desert and the stringing of 5,000,000 lb. of aluminum cable. The Big Creek plants are producing at present 70 per cent of the company's total output. Of the power sold by the company 78 per cent is used by electric railway systems, namely, the Los Angeles Railway Corporation, operating 355 miles of street railways in the city of Los Angeles, and the Pacific Electric Railway, operating 868 miles of interurban lines in southern California.

Vol. XLIV NEW YORK, SATURDAY, SEPTEMBER 26, 1914 No. 13

INTANGIBLE ASSETS OF RAILWAYS

A very popular charge against railways is that there is a great deal of water in the securities and that the extent of this inflation is represented by the difference between the par value of the securities and the value of the company's physical assets. The fact that the cost of developing a property is as legitimately a capital charge as an investment in physical property seems to some persons very difficult of comprehension. Even in official appraisals where an allowance is made for intangible assets it is often permitted grudgingly, as if it was something to which the railway was not entitled. It seems strange that this should be the case because the principle of intangible values is not one confined only to the public utility industry. It applies directly to many other lines of business, indeed to most of them, and it is recognized there as a legitimate charge against the cost of an article and as a factor in its value. In fact, if the extent to which the principle of intangible value is accepted in other lines of industry received some thought, we believe it will be found that the percentage claimed by the railway companies for this kind of asset is usually very moderate compared with that recognized as proper in other fields of trade.

INTANGIBLE ASSETS OF NEWSPAPERS

An example of this was shown this week in the recent appraisal of the estate of Joseph Pulitzer, publisher of the *New York World* and of the *St. Louis Post-Despatch.* The case is particularly interesting because the daily newspapers have usually been among the foremost to criticise the inclusion of intangible assets in appraisals of public utilities properties while they themselves form a conspicuous example of properties whose value consists very largely of intangibles. As a rule, a newspaper's tangible assets are few and inconsiderable, probably a printing office and possibly a building. Its chief asset is its reputation for supplying the news which a considerable body of readers want. This asset is purely intangible in character, but that it may be considerable in amount is shown by the Pulitzer appraisal and in the case of the *World* was placed at 24 per cent of the total value, and, in the case of the *Post-Despatch,* at 67 per cent of the total value. It would not be difficult to point out examples of intangible assets in other lines of business, but as the newspapers are fond of criticising the inclusion of intangible assets in railway valuations and as the principle involved is not different, this example is perhaps as good a one for them as any.

A DEPRECIATION RÉSUMÉ

Elsewhere in this issue we are publishing an extended analysis of the various kinds of public utility depreciation. Instead of spinning some new fine-drawn theories on depreciation, Mr. Fitting has endeavored to present the best thought on the subject, and the result is praiseworthy. While the student of depreciation problems will be interested chiefly in the clear-cut delineation of depreciation theory and practice, the value of the article to the layman lies mostly in the emphasis given to this point—that different reasons for calculating depreciation exist and therefore different methods of calculation may be used. Depreciation connected with appraisals involves the problem of the proper rate; depreciation as it concerns the financing of renewals deals with the creation and maintenance of adequate depreciation funds. In the latter case the use of a percentage of gross earnings to cover both maintenance and depreciation is eminently satisfactory. As long as it approximates the current and future expenditures, the discrepancy is not noticed. The chief point at issue in appraisal work, however, is that past and future depreciation should be determined as exactly as possible in order to give a sound basis for establishing the equity between capitalization and physical value, or for determining the basis of a "fair return."

METHOD TO BE USED

As to what scientific method of calculating depreciation should be used in appraisal work, we believe no general answer can be given. As Mr. Fitting says, the straight line, 50 per cent and mortality methods may all be sufficiently accurate, but engineers and accountants have not yet and probably will not in the future be unanimous in their support of any particular method. Difficulties or discrepancies under each method that seem negligible to one seem insuperable to others. As a matter of fact, the complexity of the general factors concerned in appraisal work and the dissimilarity of factors in individual cases make standardization of the subject seem impossible. Especially is this true in view of the uncertainty of estimating the life of property and the confusion regarding the very meaning of the term "depreciation." Each year, however, the question of calculating and accounting for depreciation is receiving greater attention, and two or three methods may finally be settled on to the exclusion of all others. In view of the present state of development of the question, as shown in Mr. Fitting's résumé, one can at least be optimistic in regard to such an outcome.

IMPORTANCE OF SPECIAL WORK MAINTENANCE

Unquestionably the most expensive part of track construction in paved streets is that contained in the special work. This is especially true when the traffic demands the best quality of materials, such as are used in hard center or solid manganese work. On the other hand, there is no single part of the railway equipment which receives so small a proportion of its proper attention and maintenance. Usually every precaution is taken at the time of purchase to secure good material and install it properly, but after it is installed the road department tries to forget about it. The track foreman does not call attention to defects until they have reached a point where they are dangerous, sometimes because his territory is too large for him to give proper attention to the initial stages and sometimes he is incompetent and not a close observer. In the solid work little or nothing can be done when a defect does occur, unless it is a question of joint or foundation trouble. Repairs can be made in insert work, and usually the first difficulty to arise is that of a loose insert. The insert does not become loose instantaneously; instead it becomes so gradually and in so doing reveals its condition before it reaches the danger point, or at least before it becomes so defective that it reflects its condition in the substructure, as well as in the rolling stock.

As a rule it may be said that with the larger companies, that is in cities of 100,000 or more, or on properties where the track mileage is of corresponding length, experienced gangs should be retained who can devote their entire time to insert repairs and renewals. If this is done not only is an increased life in a given layout insured, but many other defects dependent upon the excessive impact blows brought about by the loose insert are eliminated. With the smaller companies the question of special work maintenance is a difficult one to solve except where the traffic is so light that a loose insert is an extraordinary occurrence. On the other hand, many manufacturers now retain experts in this work, and are in a position to furnish them to railway companies when insert renewals or resetting is required.

If the substructure has been carefully prepared, the foundation properly installed, the right arrangement and lengths of ties used, and the proper type of special work employed, track special work maintenance even then is a problem of eternal vigilance and prompt repairs. Probably the mechanical joint is the weakest point in the special work layout structure. It has been suggested that this, too, could be improved if a riveted joint or some type of welded joint were employed in its place. While this would involve other complications, such as making renewals more difficult and not allowing for expansion or creeping at street intersections, the latter difficulties could be obviated in the tangent track. The elimination of the mechanical joint in a special work layout should so increase its life that the slight increased cost of renewals would be worth while. Moreover, if the welded, riveted or anything other than the mechanical joint is worth while in tangent track construction, it certainly should be economical in special work layouts where the amount of money invested per foot of length of track is many times that of straight track construction. Of course, in some instances it might be practically impossible to make the weld or apply the rivets owing to limited clearance, but in these cases treated bolts could be used in reamed holes with a driving fit. At the same time a perfect fit between the rail and the joint should be had to eliminate lost motion and thus insure a result equaling in a measure the more permanent types of joints.

POSSIBLE PIT PERFECTION

It is very gratifying to read in the office of the superintendent of equipment the thorough schedule of inspection duties set down for the instruction of the pitman, but it is rather disconcerting to find that working conditions at the pit make it a sheer impossibility to obey the schedule requirements. We regret to say that pit betterments have not kept pace with other improvements in shop layouts. That this neglect cannot be due to a lack of good models will be evident from the following consideration of what has been done by a few progressive railways during the last decade.

About ten years ago one of the large Eastern companies installed in several of its car shops the indirect or blower system for heating the pits. This system is still in operation to-day and is proclaimed by its users as far superior to any form of steam heating for the following reasons: First, the hot-air outlets can be adjusted to suit the convenience of the near-by workmen far more readily than a steam layout; second, unlike pipes or radiators, the outlet covers are almost flush with the pit walls so that maximum working space is obtained while all chance of burns or scalds is eliminated; third, in contrast to the unavoidable leakage of a steam system, the heat comes in the form of dry air which removes even the humidity due to dripping cars and general atmospheric conditions; fourth, the forced-draft system embodies also good ventilating qualities and so dissipates unpleasant odors; fifth, and best, it is reversible because it is just as available for furnishing cool drafts in summer as warm drafts in winter. The extra cost of the indirect system should therefore not deter the operator of closed pits from using a heating and ventilating system that so clearly promotes the work of the men to whom the most disagreeable yet most important part of car maintenance is assigned. The fact that a certain railway turned to steam after trying forced draft shows simply that a good installation is not to be obtained by guesswork but by scientific design.

In like manner, on most properties, the design of pits for the different purposes of inspection and repair leaves much to be desired. It is only too common to see a man obliged to work alongside a truck in the attitude of a Japanese contortionist when a properly located niche in the wall of the pit would allow him to work standing erect. Again, instead of kneeling alongside or bending over to pack a journal box, the same work could be done from a convenient sitting posture if the devil-strip was built with a wide gutter or depression alongside the rails. These suggestions, drawn as they are from the practice of alert railways, can be followed to good advantage by every railway which wants to get the best results possible from inspection and maintenance in closed pits.

RELIEVING TRAFFIC CONGESTION IN LARGE CITIES

Conspicuous efforts have been directed within the last few months toward improving vehicle, street railway and pedestrian traffic conditions at the main street intersections of large cities. Until lately, regulation of traffic has not received the attention in our Eastern cities which is commensurate with their density of transportation. It is encouraging, however, to note the recently increased number of experiments and the extension of old systems and adoption of new methods along these lines. These innovations fall roughly into two classes: first, systems designed primarily to protect the pedestrian while he is crossing streets and waiting for cars; and, secondly, systems designed primarily to facilitate the movements of cars and vehicles.

Experiments of the first-mentioned class, namely, those primarily affecting pedestrians, include mainly the establishment of various types of safety zones, where prospective passengers may await approaching cars without danger from automobiles and other vehicles. The success of the simple type of painted zone, as tentatively adopted on Broadway, New York City, depends largely on a more rigid police observation than has yet existed to enforce non-encroachment by vehicles and also upon more scrupulous street cleaning in winter to prevent the painted zones from becoming indistinguishable under snow.

The use of the more easily recognizable iron standards to mark off safety zones, in vogue in several cities and spreading in popularity, offers passengers more certain protection from vehicles, without requiring the close police supervision necessitated by ordinary painted zones. Raised isles of safety, though more expensive than movable standards, present a neater and more well-defined and permanent appearance, facilitate boarding and alighting from cars, and serve as convenient platforms for passengers transferring from urban to interurban service, as in the case of the Public Service Railway in Newark, N. J. The very permanence of raised isles of safety, however, may prove a hindrance in overcrowded cities where mobile traffic laws and conditions are likely to demand a relocation of the zones. The advantages claimed for safety zones in general, in that they protect car passengers and bunch them so that less time is lost in boarding and alighting from cars, is well justified by the results obtained by cities which have established them. With an eagle eye and stiff backbone on the part of the police the safe approach to zones may be increased, as in Detroit, by parallel painted lines at the crossing, outside of which pedestrians may not venture.

The second type of experiments, namely, those designed primarily to facilitate the movements of cars and vehicles, relates to the handling of traffic by policemen. Philadelphia's new semaphore signal system, erected at her busy Chestnut and Broad Street crossing, is a valuable improvement over the ordinary whistle-and-beckon method. Its easy operation simplifies the distracting work of the local traffic policeman and enables his signals to be made visible at a greater distance to the drivers in the rear. The "multiple-unit" traffic control system, tried on Fifth Avenue, New York, in which one officer flags orders to his comrades for some distance down the avenue, should prove a helpful suggestion for creating a more simultaneous movement of traffic and involve less frequent delays. This course seems to be a logical answer to the question, why, if two sections of an artery are severed, apply more than one tourniquet? This system has hardly yet had a chance to demonstrate its worth under the most severe conditions, since it was attempted only during light summer traffic. Another fresh development of efficient traffic control is Cleveland's ingenious electrically lighted signal controlled from a booth which also contains connections with the police and fire alarm circuits, so that the street may be cleared for the rapidly moving emergency vehicles. The very latest move in the right direction is Brooklyn's new regulation on Fulton Street which prohibits vehicles from crossing the streets except at street intersections, an especially wise provision for a busy surface car route which is flanked by elevated railroad pillars.

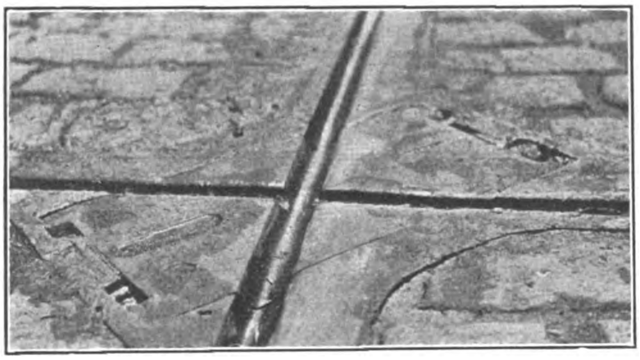
The two classes of traffic relief, outlined above, are dependent on each other and should be combined in so far as conditions of traffic density, pavement and location of tracks, width of streets and character of police service permit. For example, safety zones may facilitate interweaving of traffic by forming points around which vehicles should be made to turn in a counter-clockwise direction, branching to the right at the desired street. The counter-clockwise movement may be made even smoother by clipping off pointed curb corners, where feasible, as performed in Columbus Circle, New York, and at City Hall, Detroit. To show another illustration of interdependence: If safety zones for cars on narrow streets are to serve their purpose without merely obstructing the way, public parking and cab-stand privileges must be abolished. When the present embryonic attempts at systematizing traffic prove definitely practicable or abortive, the weeding out of useless systems through the natural law of survival will reduce their number to only a few of the tried-and-true type. A standardization of highway regulations would be of immense benefit to the safety of the stranger, as illustrated by the feeling of heart flutter experienced by the average American on crossing a "left-handed" London street for the first time.

At the present time this problem of traffic relief is being extensively investigated by safety committees, traffic committees, municipalities, police departments and other public-spirited individuals, and considering the zeal now directed toward loosening the Gordian traffic tangle it is hoped that the near future will see the congested and dangerous centers of our large cities rendered much more suitable pleasure haunts for the octogenarian.

Examples of Insert Special Work Failures

An Illustrated Presentation of the Various Typical Forms of Imperfections Discussed in the Article in the Issue of Sept. 19 Entitled, "A Study of Insert Special Work Failures"

Examples presented in the accompanying views are intended to be typical of the conditions found in various types of insert work under different traffic conditions. As mentioned in the article entitled "A Study of Insert Special Work Failures," published in the issue of this paper for Sept. 19, the most prominent form of defect developing in insert work is the loose insert plate. As a result of this study it is considered impossible to set any average length of time after which inserts will loosen under given traffic conditions. It may be stated that a large number of inserts become loose during their wear-life and must be renewed or reset periodically. Loose inserts may appear within a few weeks after installation, or it may be years before they do so.



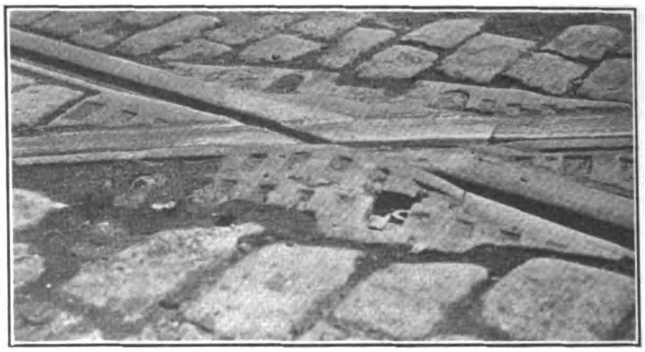
INSERT SPECIAL WORK—FIG. 1—INSERT WITH SPELTER BEARING AND KEYED-IN FASTENING, JUST BEGINNING TO LOOSEN

Installed September, 1910; traffic, fifty-five wheels per hour

EXAMPLES OF LOOSE INSERTS

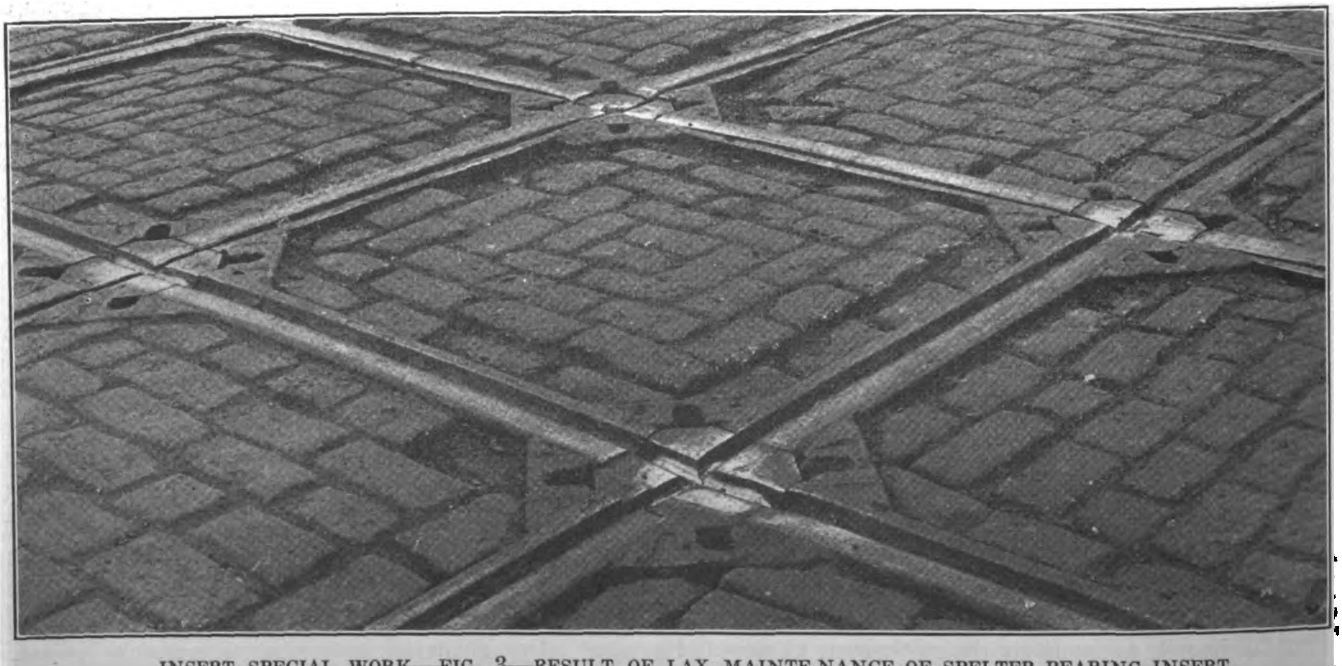
Fig. 1 shows an example of a keyed-in manganese insert supported on spelter which has just begun to loosen. The main casting is of steel, consequently this is about the only defect that will occur. The spelter has begun to loosen around the keyways, and the insert has begun to move under traffic. This particular frog is built of a 9-in. 129-lb. rail section, and has been down since September, 1910, with an average car service of 55 wheels per hour or 206 tons per hour over it during its life.

While it is believed that the acute-angle inserts do not loosen as often as those used in obtuse-angle frogs, they do occur. Fig. 2 shows an example of an insert, renewable from the pavement surface and set on a spelter bearing. The frog is built of 9-in. 129-lb. rail and was installed in March, 1911. One of the fastenings has become loose, and the insert is loosening in the pocket. Unquestionably, however, immediate attention would relieve this situation, or, at least, would postpone the necessity for resetting for some time. The fact however, that the insert has become loose in the pocket indicates that it must be reset ultimately. The average number of wheels passing per hour over this frog is 102 and the average tonnage per hour is 382.



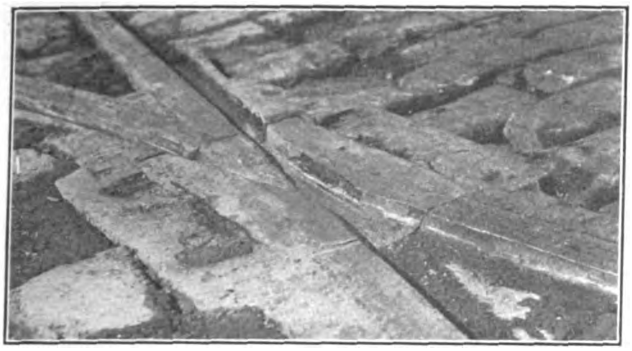
INSERT SPECIAL WORK—FIG. 2—INSERT WITH SPELTER BEARING AND LOOSE PATENTED, BOLTED FASTENING IN NEED OF RESETTING

Installed March, 1911; traffic, 102 wheels per hour



INSERT SPECIAL WORK—FIG. 3—RESULT OF LAX MAINTENANCE OF SPELTER BEARING INSERT

Installed September, 1907; traffic, 153 wheels per hour



INSERT SPECIAL WORK—FIG. 4—STYLE, ACUTE-ANGLE SPELTER-BEARING INSERT WITH PATENTED BOLTED FASTENING, WITHOUT THROATWAY GUARD

Installed November, 1909; traffic, 150 wheels per hour

An excellent example of what may be expected from lax track maintenance, is shown in Fig. 3. This is a cast-iron-bound manganese, renewable insert crossing installed in November, 1909. These inserts are supported entirely on spelter and are fitted with fastenings so that they are renewable from the pavement surface. While the crossing shown has given excellent service, its wear-life limit would not have been reached at this time except for the loose inserts. Of course the loosening of the inserts is chargeable to the design rather than to the manner of installation, but the complications which were caused by the loose inserts were clearly chargeable to the roadway department. In this illustration it will be noted that the inserts at all four corners of the right-angle crossing are loose, the spelter is entirely gone around the edges, and the inserts have pounded down below the rail surface. Most of the inserts have dished under the severe impact blows, and the arms have rounded over to meet the surface of the inserts. Resetting or replacement of these inserts is practically impossible, although a fairly good job could be accomplished by resetting and grinding the running rail arms. The average traffic over this layout is 150 wheels, or 562 tons per hour.

Fig. 4 is an old-style, acute-angle, hard-center frog, renewable from the surface and set on a spelter bearing. There is no throatway guard, consequently there is clearly defined wear in the throatway at the point where a wheel enters the insert plate. Wheels in a canted truck strike this point and are righted before they pass through the insert throatway. This frog was installed in September, 1907. It is built of 7-in. 95-lb. T-rail. The insert has been reset several times, and it is probable that the loosening of the insert may be charged to failure to provide a guard to lead wheel flanges into the insert. Traffic moves over this frog in two directions at an average rate of 153 wheels per hour during the entire year.

Figs. 5 and 6 show typical examples of the complications arising as a result of loose inserts. In this installation, which was laid down in March, 1911, all of the inserts are loose, causing the wheels to pound over the intersecting flangeways. This forces the frog to pump on its foundation, and this pumping action, in the presence of water, forces the sand cushion from be-

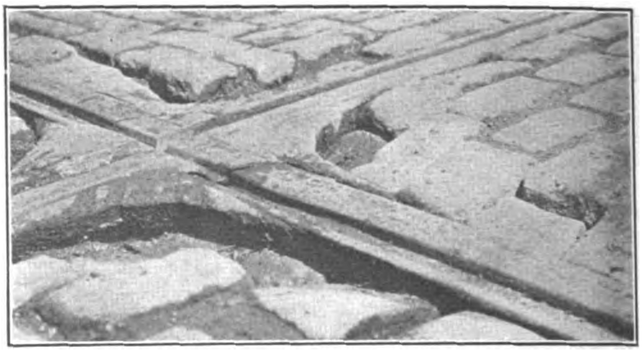
neath the paving blocks and allows them to drop and form serious ruts. These inserts are of a keyed-down, spelter-supported type. The condition of the layout as well as the surrounding pavement is not chargeable to the manufacturer, but to the railway. The inserts are still in good condition and should have been reset as soon as they became loose.



INSERT SPECIAL WORK—FIG. 9—RIGHT-ANGLE FROG IN SAME LAYOUT AS FIG. 8, LOOSE ARM FURTHER ADVANCED

The insert plate in Fig. 6 became loose from one of two causes. Either the spelter around the edges broke away from that forming the bearing and was picked up by traffic, or the spelter bearing flowed, or became compressed, or did not properly fill the interstices betweeen the plate and the pocket floor. In either case the fastenings were partially released. As a result the wheel impact at the intersecting flangeway has dished the plate by depressing it into the space originally occupied by the spelter bearing, a condition which would not occur with a machined bearing. The effect of the dishing on the manganese steel plate was to break it, as shown in the illustration, and was due either to fatigue in the metal or because the plate was slightly brittle when it came from the annealing process.

Loose Rails in Casting

Loose and broken rail arms in the cast-iron-bound work are the second form of defect which is most common. Figs. 7, 8 and 9 are examples of the beginnings of loose arms. In Fig. 7 is shown a 6-in., 70-lb. T-rail, iron-bound, right-angle frog, installed in April, 1908. The insert in this is renewable from the pavement surface and is supported entirely on spelter. The

INSERT SPECIAL WORK—FIG. 12—BROKEN RAIL IN CASTING WITH 9-IN. 92-LB. RAIL

Installed 1905, removed 1914; traffic, combination city and interurban

insert is loose and one rolled rail arm has loosened in the main casting. An examination of this frog on the ground indicated that the arm is broken in the casting. The cause of this failure may be attributed to a settling of the foundation under the intersecting flangeways of this frog and the one adjoining. This brought a transverse breaking strain on the arm, when the load was applied, just at the edge of the insert plate. The defective pavement is the result of the pumping or springing movement of the frog. Traffic moves over this frog in two directions at an average rate of 124 wheels per hour.

Fig. 8 illustrates a manufacturer's problems, for not only are all of the arms in this frog loose, but a number of arms are also loose in other frogs in this layout. Fig. 9 shows one of these in which a loose arm has become more pronounced and, in pumping, has removed the sand cushion from beneath the pavement and produced ruts aroung the frog. It will be noted in Figs. 8 and 9 that the inserts are tight, although they have been in service since November, 1910. These are of iron-bound, rolled-rail-arm construction, with the inserts bolted down on a partially machined bed. The looseness of the arms is to be attributed to the use of a too small grip area between the casting and the rolled-rail arm. These frogs are constructed of 9-in., 129-lb. girder grooved rail. The average traffic over them is 154 wheels per hour.

Fig. 10 shows still another example of the beginning of arm loosening in cast-iron-bound work. A crack has developed along the edge of one of the running-rail arms where it joins the binder casting. The trouble here appears to be due to unequal bearing on the foundation, bringing undue strains on the rolled-rail arm. This frog is of the machined-pocket type, and it is built up of 7-in. 108-lb. girder grooved rail. It was installed in April, 1911. Traffic moves two ways over this frog at an average of 142 wheels per hour.

Although loose arms occur under city traffic, as shown in Figs. 7, 8, 9 and 10, their occurrence is more frequent under interurban traffic, where the loads are greater. Typical defects of this kind under a combined interurban and city railway traffic are illustrated in Figs. 11 and 12. Fig. 11 shows an installation made in 1905 and removed in 1914. It was built up of 9-in. 117-lb. girder grooved rail and set on an 8-in. concrete slab foundation, with a 2-in. gravel ballast cushion. The break began in the base of the rail at the edge of

the casting, continuing through the web by way of the weakest section, and running out under the ball of the rail where it joins the insert pocket.

Fig. 12 shows a 9-in. 92-lb. rail, iron-bound, insert frog installed in 1905 and removed in 1914. Its failure was caused by a break in the rolled-rail arm at the edge of the binder casting. This break may have been due either to unequal foundation bearing or to the partial annealing effect on the rolled-rail arm when it was set in the casting. The frog in Fig. 12 undoubtedly would not have failed in this manner if a heavier girder grooved-rail section had been used.

In Fig. 13 is shown another example of loose arms, but, in connection with this frog, a broken casting has occurred. This right-angle frog was built up of 9-in. 117-lb. girder grooved rail. The character of the failure indicates that there was settling of the frog along the line of the break. This tended to elevate the rolled-rail arms which intersect the break tranversely, resulting in a fracture along the line of least resistance between the casting and the rolled-rail arms.

CUPPING IN THE FROG ARMS

A form of defect which is less common than the others mentioned, yet which is found in a few instances and in practically all classes of iron-bound work, is the cupping of what appears to be soft rail at the point where the rolled-rail arm joins the insert. Figs. 14 and 15 show typical examples of this. Fig. 14 shows a cast-iron-bound, 9-in., 125-lb. girder grooved rail, acute-angle frog with an insert supported on a machined pocket, which has been in service since July, 1904. While this example is not exactly typical, since the piece has given such excellent service, it does show the character of the failure in question. Fig. 15 shows a cast-iron-bound, manganese insert, acute-angle frog built of 9-in. 125-lb. girder grooved rail in which the insert is

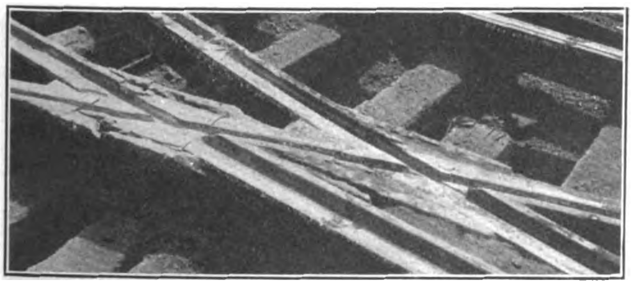
Traffic, combination city and interurban

entirely supported on spelter. This is also a very old frog which has been in service since August, 1903, but it serves to show the effect of cupping in the rolled-rail arm. In this particular instance the ball of the rail has been mashed down over the web.

EXAMPLES OF BROKEN CASTINGS

A type of failure more common to interurban railway than to city railway track special work, is the broken casting. In every instance noted in the large number of layouts inspected during the course of this study, the failures of this type were in the cast-iron-bound insert work rather than the cast-steel arm work. As a rule defects of this kind occur in acute-angle frogs and in switches and mates, and no doubt they are due to transverse bending strains applied to castings which are too small in section to withstand them.

As pointed out in last week's issue, the remote cause may be either the use of an improper foundation or of a casting inherently too light. The following examples illustrate the efforts of both of these sources of weakness.



INSERT SPECIAL WORK—FIG. 19—BROKEN CASTING IN FROG, WITH SAME LAYOUT AS FIG. 17; BEARING PLATE
Installed and repaired; traffic, combination city and interurban

Fig. 16 shows an example of an acute-angle frog in which the casting has broken through the center. This frog was built up of 9-in. 117-lb. girder grooved rail with the insert keyed down on a spelter bed. Traffic over this particular frog included 24-ton double-truck street railway cars and 45-ton double-truck interurban cars. It was installed in 1905 and removed in 1914. The installation was made on an 8-in. concrete slab with a 2-in. gravel ballast cushion beneath the ties. Special ties were not used, but standard ties were so spaced as to transmit the track loads to the foundation uniformly. While it is impossible to state the actual cause of this break, it is believed that the casting was too small for interurban traffic. Again the small size of this casting, in combination with an unequal bearing on the track foundation, either in the original installation or as a result of impact blows dealt in the intersecting flangeways, caused the casting to become a suspended point, and the break occurred under a heavy wheel load.

Figs. 17, 18 and 19 show three frogs in a single layout in which 7-in. girder grooved rail was used with a 7-in. 108-lb. guard rail. This layout was installed in 1905 and comprised cast-iron-bound work with renewable inserts supported on spelter. One rail in the frog, shown in Fig. 17, was not regularly operated, while the rail beginning at the bottom of the illustration and disappearing at the top, is used by street railway cars. The average service includes a two-minute headway with double-truck, 20-ton cars. This layout was installed on wooden ties with an 8-in. concrete slab foundation and a 2-in. gravel ballast cushion. Traffic over it has been light throughout its life, consequently it is believed that the shallow depth of the casting and the poor grade of the cast metal are real causes of the break in the casting. It is also possible that the non-uniform character of the foundation was a contributing cause.

Fig. 18 shows also a cast-iron-bound frog built of 7-in. 108-lb. guard rail. Neither the running rail nor the insert in this case shows unusual wear, yet this layout must be renewed because the casting has broken. An average two-minute headway with double-truck city cars in conjunction with 45-ton interurban cars every half hour, make up the traffic over this layout. The track was installed in 1905, and for the past four years the casting at the side of the insert has been broken. In an effort to repair the layout, plates have been bolted on the sides to hold the hard center in place, and a heavy plate inserted beneath the two frogs to give it additional support. The break in the casting may be attributed to the use of 7-in. rail in special work over which 45-ton interurban cars are operated. Fig. 19 is another view in the same layout and is similar to the one shown in Fig. 17, over which half-hourly interurban service and two-minute headway by double-truck city cars are maintained. The plate beneath the frog was inserted in making repairs in 1912.

Depreciation

An Extended Analysis of the Different Kinds of Depreciation Which May Occur in the Physical Property of a Public Utility Company, the Various Methods Evolved for Computing This Depreciation and a Comparison of Their Merits and Demerits

BY RALPH U. FITTING, WITH HARRIS, FORBES & COMPANY, NEW YORK

The physical property of an operating company which has been long in use will show loss in value and utility, no matter how well maintained. The earning power may not be diminished thereby, but inevitably a certain portion which cannot be replaced will have worn away and can only be brought to full value and utility by complete renewal. This may be a large or small part of the total value, depending on its characteristics.

Obviously, repairs cannot be continuously made to keep the investment to its full worth. For example, it is impossible to replace the wear on rails or overcome the ravages of chemical deterioration due to rust and decay. Therefore, admitting the gradual reduction in value of the physical property (not real estate), some method must be used to determine the loss in value.

The question arises as to what is "depreciation," and whether it is the: (1) deterioration of money value; (2) deterioration of utility value; (3) necessary amount to keep the investment in constructed property up to 100 per cent.

Depreciation is really definable by any of the above, depending on the particular use to which it is to be applied and point of view.

USES FOR CALCULATING DEPRECIATION

In general, there are three distinct uses for calculating depreciation, as follows: (1) equity for capitalization from estimated appraisal duplication value; (2) depreciated duplication value for rate-making purposes; (3) annual reserve which is to be taken from earnings to offset depreciation due to various losses in order to keep physical property up to 100 per cent.

In the first case, in determining value at the time of appraisal to indicate the equity between physical worth and capitalization, depreciation covers the loss of value due to past operations.

In the second case, it is not only necessary to determine depreciation due to past operations to find total investment on which to base "fair return" but also to estimate depreciation on future operations in order to safeguard owners.

In the third case, the application is somewhat different, since depreciation is represented by an accrued fund made up from earnings to offset the reduction in investment due to losses in value (and losses in utility in so far as worth is affected) to provide for renewals made necessary. These requirements may be brought on also by reason of age, obsolescence, inadequacy, changed demand, etc. Such funds by usual practice are accrued by monthly or yearly reserves to offset the original cost within the estimated life.

The depreciation fund so accrued may be used in any of the following ways:

1. A fund accrued against each piece of property and held as an invested fund during the life of such piece of property.
2. If the fund is general it can be used for replacements without particular reference to locality in order to maintain the physical property as nearly as possible to a constant value.
3. The fund can be kept in bank and used to purchase bonds of the company.
4. The fund can be reinvested in extensions of the company's property.
5. The fund can be used to purchase the securities of other companies.

If depreciation is not provided for by a reserve fund, then it must be considered to be provided in one of the following ways:

1. By current repairs and replacements all charged to maintenance as required.
2. By expenditures from surplus as required.
3. By distribution as dividends out of earnings to offset probable loss in investment.

Depreciation is not to be confused with bond sinking funds.

Bond sinking funds and depreciation accruals are more or less analogous in so far as they relate to the protection of the investment, and the tendency in modern financing seems to be away from the establishment of bond sinking funds as such and to establish in lieu a "sinking or renewal fund," in which case the company has the option of using such fund for purchasing its own bonds or using it for extensions. Obviously, against such extensions no further bonds can be issued, since the investment is increased purposely to protect the bonds outstanding.

The line of demarcation between maintenance and depreciation is not well drawn nor are the definitions by the commissions clear on the difference; in general, however, each may be determined by the effect on the life of the equipment concerned.

If the changes do not increase the life of the equipment, the expenditure may be considered as covered by maintenance; if the life is lengthened, then it is depreciation. The safest way, therefore, is to consider maintenance and depreciation as collated and to be provided out of the same fund.

It is plain, therefore, that depreciation is a loss of value which must be made to keep the investment uniform, in the case of a bonded debt, either by increasing the investment or reducing the bonds outstanding in order to keep the margin of security uniform; and for appraisal purposes find the reduction of the estimated duplication value from new value for the purpose of determining equity for capitalization or for rate-making purposes.

KINDS OF DEPRECIATION

The various kinds of depreciation, from the standpoint of loss of value, may be classified under two heads: (1) physical depreciation, and (2) functional depreciation.

Physical depreciation (or the natural) is the result of decay and begins immediately after installation.

Functional depreciation is the result of lack of fitness for function, as changed surroundings, growth of business, improvements in the art, etc. Functional depreciation is indeterminate for future conditions and may or may not be necessary in the lifetime of a particular piece of equipment.

The following constitute the various classes of depreciation:

1. Natural Depreciation—The loss of value due to

wear and tear, and to chemical changes in physical structure, as rust, decay, electrolysis and general natural deterioration.

2. Obsolescent Depreciation—The loss of value due to improvements in the art by improved design, inventions and discoveries. These are too numerous to mention all, but some are the advancements in arc lighting, steam turbines, high-voltage lines, electric railways, etc. However, these may not affect all companies alike, for what may be considered obsolete for one may be entirely suitable for another.

3. Inadequacy or Supersession Depreciation—The loss of value due to the necessity of replacing equipment before the expiration of its useful life because of extraordinary requirements or insufficient size or capacity. For example, the building of underground distribution systems to take the place of overhead wires, as required by municipal authorities; or the removal of generating units for installation of larger capacity units made necessary by growing business; or replacing of rails with heavier steel on account of increased traffic.

4. Price Depreciation—The loss due to reduction in unit prices may be on account of: (a) a temporary business depression, (b) improvements in manufacture, (c) reduction of transportation rates, or (d) tariff changes. If depreciation is calculated for an appraisal, consideration should be given to price depreciation if the replacement method is employed. If the historical method of appraisal is used, price depreciation will not enter.

5. Demand Depreciation—The loss due to decreasing demand for the product and therefore for the use of the plant. As for example, in the case of mining operations where in certain districts the ore or coal may become exhausted or in a timbered district where timber gradually becomes logged off.

6. Accident Depreciation—Some have advocated the necessity of classifying the losses due to accidents and destruction of property to depreciation. This seems beyond the scope of functional depreciation and enters into the field of insurance. The destruction of property, due to fire, floods, tornadoes and earthquakes, or the failure of structures, such as dams, bridges or buildings, due to improper design or the loss of property or life due to collisions, wrecks, boiler explosions or bursting of flywheels, do not seem rightly to belong within the scope of depreciation. Usually, in cases of accident losses which are extreme, the stockholders carry the burden by loss of dividends.

METHODS OF COMPUTING DEPRECIATION

Various rules and methods have been evolved for the determination of depreciation, some only for the purpose of appraisal and some for accruals as required in accountancy. Most of the methods can be used for either.

In general, all of the methods of computing depreciation of equipment, physical property, etc., begin with an assumption as to the probable life of the particular piece of apparatus to be depreciated, and some very elaborate formulas, on academic theories, have been derived. Many of the refinements introduced overlook the chances of great error which may be made by the necessity for estimating losses due to future uncertainties, and also overlook important points as to the practical structure of component parts of apparatus and equipment. For example:

There are very few things in present-day affairs with which we come in contact that are by themselves of simple elementary structure. Buildings are constructed of steel, stone, wood, brick, cement, etc. Though each of these are elemental in themselves, they are again made up of complex structure; each part of which when in a finished building is subject to stress and depreciation, and each part will have a definite life and may or may not on its failure cause the failure of the particular structure of which it is a part. This applies not only to buildings but to equipment, apparatus, machinery, distribution systems and all constructed parts of physical property.

The great number of factors, most of which have to be estimated, and which in no two problems will follow the same laws, have been the reason for the great difference in opinion as to the proper method of computing depreciation and have made possible the variety of ways and means as brought forth by authors on the subject.

The following summary covers some of the various methods of computing depreciation which have been used:

I. The Straight Line Method assumes a definite life and a uniform rate of depreciation within that time.

II. The Sinking Fund Method assumes a definite life, and by sinking fund formula with any percentage rate of accrual provides for a fixed sum yearly bearing interest which will offset the assumed value in that period.

The fund that will accumulate at the end of any number of years, through the annual laying aside of a uniform amount and putting that out at compound interest, is determined by the following formula:

$$F = \frac{(1+R)^N - 1}{R}$$

The sum to be laid aside annually at compound interest to accumulate a given amount at the end of a number of years is determined by the following formula:

$$D = \frac{FR}{(1+R)^N - 1}$$

Where F = the accumulated amount in dollars at the end of N years,

D = the annual amount of dollars laid aside at interest compounded every twelve months,

R = the annual rate of interest expressed as hundredths of a dollar and

N = the number of years the amount is annually laid aside.

III. The Arbitrary Method with Decreasing Payments Towards Maturity assumes the setting regularly into a reserve fund arbitrary amounts diminishing towards maturity. The total amount accumulated within the period will equal the total assumed value.

IV. The Arbitrary Method with Increasing Payments Towards Maturity. This is similar to No. 3, except that it assumes the setting into reserve of increasing payments yearly.

V. The Service-Output Method assumes a fixed percentage which will equal the value at the end of the period based on the output in units.

VI. The 50 Per Cent Method assumes in any system composed of like things which have been in service continuously and are replaced as they become worn out that the average remaining life of the entire is 50 per cent. Therefore the depreciated value is 50 per cent of new cost plus salvage value.

VII. The Insurance Method assumes a theoretical life, in that money will not be needed for depreciation until required and should be spent in the year created for replacement of parts of the equipment.

VIII. The Unit Cost-Depreciation Method assumes a definite life, and depreciation is determined from the increased cost of operation as compared with new equipment by a modification of the sinking fund formulas as follows:

$$c = \frac{y}{d+r}\left(\frac{Q+P+DC+rC}{Y} - \frac{q+p}{y}\right)$$

Where C = first cost of new plant unit.
c = depreciated value of old plant unit.
D = sinking fund annuity which will accumulate \$1 in life of new plant unit.
d = sinking fund annuity which will accumulate \$1 in the remaining life or n years.
P = annuity to provide for repairs to parts of the new plant unit during its life of N years.
p = annuity to provide for repairs to parts of the old plant unit during remaining n years.
Q = average annual operating expense, exclusive of repairs but including taxes, during N years.
q = average annual operating expense, exclusive of repairs but including taxes, during remaining life of n years.
r = rate of interest expressed as a decimal.
Y = average annual number of units of product during entire life of N years.
y = average annual number of units of product during remaining life n.

The value of D and d are to be found by the following sinking fund formulas:

$$D = \frac{r}{(1+r)^N - 1}$$

$$d = \frac{r}{(1+r)^n - 1}$$

Where N = number of years of life of new plant unit.
n = number of remaining years of life of old plant unit.

It frequently happens that $Y = y$ as in the case of fixed plant units, like buildings, railway ties, etc., that perform an unvarying service throughout their lives. Then the formulas resolve into:

$$c = \frac{(D+r)\,C}{d+r}$$

or

$$\frac{c}{C} = \frac{D+r}{d+r}$$

IX. The Annuity Method assumes a definite life, and equal annual amounts are set up sufficient to provide at the expiration of the estimated life an amount equal to the original cost, plus interest on the investment. The annual interest is computed on the unexpired part of the investment and is subtracted from the equal annual amounts so set up to obtain the annual depreciation charge. The sum of the annual depreciation so obtained will equal the original cost.

X. The Reducing Balance of Cost Method assumes a definite life and that the total depreciation will equal the original cost, which is divided into annual amounts obtained by a fixed percentage of the remaining residue of cost after subtracting depreciation of the previous years. At the end of the assumed life the entire original cost will have been written off.

XI. The Mortality Method assumes that depreciation follows the general curve of human mortality with slowly increasing rate during middle life and slowly decreasing rate toward later life.

XII. The Per Cent of Gross Earnings Method assumes that the depreciation and maintenance of physical property can be covered by a fixed percentage of gross earnings.

DISCUSSION OF METHODS

In the following discussion the above definitions will be amplified and their application further explained, as necessary, by examples:

I. Straight Line Method—This method perhaps has been longer in use than any of the others, and is preferred and adhered to by many on account of its simplicity, and the fact that the entire subject is so problematic and so intricate that the employment of more refined methods have not been shown to be justifiable. The principal argument against its employment is that during the first few years the amount of depreciation is in excess of what seems reasonable.

II. Sinking Fund Method—There are many advocates of the sinking fund method, especially among accountants, because of the fact that the form is in line with the accrual of monthly reserves, such as are generally used for taking care of lump payments on taxes, insurance, maintenance, etc., and appeals to accountants for this reason. It has the one advantage over the "straight line" method in that the accruals for the first few years are not large. The principal argument against the employment of this method is that the increase in the depreciation reserve towards the end of the life is very fast, and that after the assumed life of the aparatus is passed the same argument should hold against negative depreciation and a sum be accrued which should be credited to the value of the equipment beyond its assumed useful life.

The following example shows the application of the sinking fund formula:

Assume a plant worth \$60,000 which is to be set aside in annual depreciation charges by the sinking fund method at interest at 3 per cent:

Year	Annual Charges to Depreciation	Interest on Sinking Fund	Total Sinking Fund
1	\$5,230	....	\$5,230
2	5,230	\$160	5,390
3	5,230	320	5,550
4	5,230	490	5,720
5	5,230	660	5,890
6	5,230	840	6,070
7	5,230	1,020	6,250
8	5,230	1,210	6,440
9	5,230	1,400	6,630
10	5,230	1,600	6,830
	\$52,300	\$7,700	\$60,000

III and IV. Arbitrary Method—Although there are not many advocates of the method of using arbitrary amounts set aside for depreciation during the assumed life of the equipment, the simplicity of the method appeals to many who are not familiar with the application of formulas. The reasons against employment of such methods are obvious.

V. Service-Output Method—The application of this method for determining depreciation is not well conceived since matters of load conditions, power factor, load factor, kind of load, maximum demand, etc., have bearing on the question of output, any one of which may or may not be severe on the operating condition of the equipment. Also this method would be impossible to apply to all physical property, and for certain classes of property would make an unreasonable basis on which to compute depreciation. For certain classes of property in using this method of determining the rate at which the depreciation takes place, it is necessary that unit of service be used, for example, in the case of car wheels and cars on the basis of car miles operated, since it is plain that the wear and tear on these will be very much greater while in service. However, to apply a unit of service, say in kilowatt hours, on a transmission line is not a proper basis, since there is no wear and tear for the transmission of electricity except for accidents causing short-circuits and burnouts.

VI. 50 Per Cent Method—The 50 per cent method has a great many advocates among the engineers on appraisal work and has been used largely by Mr. Floy on the Third Avenue Railway estimates, by B. J. Arnold for the Public Service Commission of the First District of New York, by H. P. Gillette, railroad appraiser in the State of Washington, by Prof. M. E. Cooley in the Michigan State appraisal, and it is understood has been approved by the Master Car Builders' Association. Obviously, this method is only suitable for appraisal purposes and then only to certain classes of equipment, of which there are a large number of one kind; for example, the poles of a distribution system, or meters. This method requires caution in use and should be used in connection with personal inspection.

VII. Insurance Method—This method for computing depreciation is rarely used.

VIII. Unit Cost—Depreciation Method—In a paper published by H. P. Gillette in the *Electrical World*, Nov. 2, 1912, has been outlined this method of applying depreciation and it has been derived on the assumption that the increase in maintenance expense and the decrease in efficiency due to age should be compared with new equipment in order to determine depreciation. The only place where this method can be applied is to generating equipment which has sufficient measuring instruments to obtain the data as required by the formula. This narrows the application of it down to generators and motors. For other equipment or structures, it is the sinking fund method. Theoretically, this means of obtaining depreciation may be sound, and answers derived may be considered as an accurate measure of real depreciation on account of using factors which are important from a utility value standpoint, but the great number of factors and the character of information required narrows its use to a limited degree.

IX. Annuity Method—This way of determining depreciation is of English origin and is a means of distributing the interest on a sinking fund basis, so that the charges for depreciation increase towards the end of the life. The principal objection is the necessity of carrying a larger amount in the depreciation reserve than necessary and writing off this larger amount to offset the interest charged thereto. The following example will show its application:

Assume a company with an investment of $60,000 which is to be written off in ten years by the annuity method, charging interest at 3 per cent annually on diminishing balances. The constant annual amounts chargeable to depreciation for expired investment in ten years would total $70,300, and the diminishing amounts credited on account of interest would equal $10,300.

Year	Expired Investment Charged to Depreciation	Interest Credited to Depreciation	Actual Charge to Profit and Loss
1	$7,030	$1,800	$5,230
2	7,030	1,640	5,390
3	7,030	1,480	5,550
4	7,030	1,310	5,720
5	7,030	1,140	5,890
6	7,030	960	6,070
7	7,030	780	6,250
8	7,030	590	6,440
9	7,030	400	6,630
10	7,030	200	6,830
	$70,300	$10,300	$60,000

It is interesting to note that the actual charge to profit and loss by the annuity method and by the sinking fund method are exactly the same; but, in the first case, the interest is a fictitious item, while in the latter the interest may actually be received.

X. Reducing Balance of Cost Method—This method is also of English origin, and although it has an advantage over the annuity method, is open to the objection that the rate or per cent of decrease is very high for ordinary length of life of physical property, and the depreciation during early years is at greatest rate. For example, the rates per cent required on reducing balance of cost basis in order to set aside any given amount are as follows:

Years	Rate Per Cent	Years	Rate Per Cent
100	3	28	10
72	4	26	11
58	5	23	12
48	6	18	15
41	7	13	20
36	8	10	25
32	9		

XI. Mortality Method—In a paper presented by Edwin Gruhl before the American Electric Railway Association were shown a number of curves of depreciation as obtained from actual data in incandescent lamps, water works pumps, cast-iron car wheels and also human life. In general these curves have similar shape, being a form of one-half sine wave with the greatest rate of depreciation during the middle one-third of average life.

From the information at hand Mr. Gruhl draws the following conclusions as advantages of the mortality method over the straight line or sinking fund methods:

a. Every point is determined by experience, and where a large number of instances of replacement have been utilized to determine the character of the curve, additional data will make only slight modification. It is possible therefore to generalize with insufficient data.

b. It is not dependent upon an arithmetic average and is applicable to any age, whether or not the average life has been exceeded.

c. It measures the effect of all causes of depreciation affecting the property and the effect of those causes at any age upon the average unit.

d. When sufficient reliable data are available, it will permit by actuarial methods, the calculation of the annual reserves, which, with or without interest accumulations, as the case may be, will insure the replacement of the various elements of property at the end of their probable lifetime. That there is a substantial difference between the annual reserve required for a new property and that required for one badly depreciated, readily follows.

e. It draws the line sharply between what is the rate of depreciation, the appraisal problem, and the means of financing depreciation, the reserve problem.

The principal objection to the use of the mortality method is the lack of sufficient data at the present time to determine mortality curves for all kinds of physical property. However, the method seems better suited to actual conditions on account of taking the value from results of experience than by arbitrary arithmetical deductions, as shown in the above methods. It also gives a present value in excess of other methods, by taking into account the slight depreciation during early life.

It seems, therefore, that the mortality method gives us the nearest result to actual experience, but more information is required before it can be generally adopted, and in view of this limitation, the various engineering organizations would unquestionably find it of great value to select committees to collect such data and to provide mortality curves for various classes of apparatus, equipment and physical property. The results of experience so recorded, if adopted as standards for determining depreciation, would approach as near as possible to actual results.

XII. Gross Earnings Method—With the growing tendency toward equalization of return on the investment for companies doing business of the same kind, the gross earnings are a measure of earning power and on which all charges should be based. The growing favor of this method and the satisfactory results which it gives are the greatest arguments in its favor.

The following table shows the range of percentages for maintenance and depreciation as actually required by various kinds of characteristic public utility and railroad companies.

Maintenance and Depreciation

	Per Cent Gross Earnings	
	Maintenance	Maintenance and Depreciation
Steam railroad—the Pennsylvania Railroad Company	29.5	.....
Electric railroad—Interborough Rapid Transit Company	13.85	.....
City railroad—Milwaukee Electric Railway & Light Company	11.0	22.25
Gas—Peoples Gas Light & Coke Company	6.48	10.97
Electric—Union Electric Light & Power Company	4.55	18.5
Telephone—Chicago Telephone Company	15.85	31.90

Conclusions

Reviewing the various methods of determining depreciation. Because of (1) the complexity of the factors entering into the problem, (2) the same factors in any two problems being sometimes greatly dissimilar, (3) the necessity of estimating into future conditions, (4) the uncertainties of determining the probable length of life, and (5) the abrupt end of life of apparatus or equipment not being determinable, refinement of methods for most cases are not warranted.

The conclusions to be drawn seem to be

a. For appraisal purposes to determine either present value or future value by depreciation estimate from estimated duplication value any of the following methods are sufficiently accurate: (1) straight line method, (2) 50 per cent method (when used with caution), (3) mortality method (when sufficient data have been accumulated).

b. For determination of depreciation accruals which should be set up into a fund out of earnings and to be used for maintenance and depreciation, the per cent of gross earnings method best applies.

c. For accruing the depreciation reserve from a fixed percentage of gross earnings it is best to accrue into the account the difference between the amount expended for maintenance and this percentage. The depreciation reserve is then to be charged only when expenditures are made for improvements which extend life.

d. When such expenditures are made the plant account should be credited with the entire cost of the improvement and the depreciation reserve charged. Then the new cost of the apparatus or equipment replaced is written off except for such salvage as may be obtainable.

Efficiency Department With "Safety First" Features at Tacoma

BY O. C. MATHIS, SUPERINTENDENT OF EFFICIENCY PUGET SOUND ELECTRIC RAILWAY AND TACOMA RAILWAY & POWER COMPANY

The department of efficiency of the Puget Sound Electric Railway and the Tacoma Railway & Power Company has for its objects the promotion of efficiency among employees, harmony between departments and good will of the public. Efficiency among employees may be divided into loyalty, ability and industry, so we aim to produce efficiency by increasing these qualities.

Outline of Work, Etc.

The department is trying to increase loyalty among the men by welfare work and personal influence; ability is obtained by the selection of men and education. In selecting a man we are influenced by his health, personal appearance, past record and intelligence. Educational work consists in teaching the man to be careful of passengers, self and freight; proper use of power; proper care of equipment; proper care of track; rights of the public (courtesy); care of injured and reporting accidents; necessity of and obedience to rules; observation and report of defects in the cars, lines, tracks, signals and machinery. Written and oral examinations are had on these subjects. Industry is the quality that represents a man's cash value, and an attempt to increase this is made by example, development of pride in work, and especially by never overlooking an opportunity to show appreciation of good work, good conduct and the use of good judgment.

Harmony between departments is promoted by taking care of those matters where the duties of departments overlap, that is to say, the efficiency department is used as a clearing house for those matters that are of interest to more than one department. Promotion of safety furnishes the best example of this, so, from the standpoint of safety only, the efficiency department superintends the training of trainmen and the inspection of car equipment, track and overhead line.

It is hoped that the good will of the public will be increased by presenting the company's side of questions in which the public is interested by advertising in the newspapers, by the distribution of literature on the cars and in the stations, by giving the complaints of patrons courteous personal attention and by securing for the public more careful and courteous treatment from employees.

This briefly outlines the work. As it may be of interest as to how we do the work, the following is added:

How the Work Is Done

Our welfare work to date consists in furnishing free baths, pool tables, punching bags, piano and current periodicals in the trainmen's quarters. Personal influence consists in giving each man's suggestion for the prevention of accidents or betterment of the service, etc., respectful personal attention. If his suggestion is not adopted he is told why and is satisfied that the reason is a good one. Every man is known by name and is made to feel that he is recognized as an important member of the company's operating force. In this connection I might add that those who have difficulty in associating names and faces will find it helpful to have at hand, in convenient form, a list by numbers of all trainmen, to which one can refer during the conversation and not allow the man to go away without being called by name.

It promotes loyalty to keep the man informed on the problems of operation from the financial and managerial side. Our men are told where every nickel goes, and they know that they are getting all that the company's income allows. If a man gets in the habit of criticising the company's way of doing things, he is sought and in a friendly way, wholly lacking in an air of discipline, convinced of his error. It seems that this department can get closer to a man than can the department that necessarily must maintain an atmosphere that makes discipline possible.

As ability is the result of the development of the man's natural qualities, a proper instructor during the period a trainman is breaking in is all important. An instructor should be a practical car man with experience in the shops and power department and thoroughly loyal. We do not consider technical training necessary for car men but believe that every man has an innate respect for a thing of value, so we put special stress on this point. Certainly a man is likely to give more undivided attention to running a $7,000 car over a

$10,000 piece of special work than if he has no knowledge of their values. So the trainmen are told the costs of power, equipment, track, accidents, etc. When a motorman knows that he is saving the wages of two men when his car is coasting, he will coast more, and when the conductor knows that ½ cent of every nickel he takes in goes to pay for accidents, he becomes more interested in accident prevention.

As we believe that a thorough knowledge as to the why of rules is conducive to their obedience, the rules are painstakingly explained.

Our system of reporting defects has proved satisfactory. We have thirty boxes containing "safety first" cards located at as many places in the shops, carhouses, trainmen's quarters, track and line department headquarters, storeroom and general offices. Above each box is a notice to the employees explaining the use to be made of the cards, and instructions about what to do with them when they are made out. No information obtained in this way is used as a basis for disciplinary action. The receipt of each card is acknowledged and the substance of the information reported to the proper department, or the matter is attended to by the efficiency department direct, as the case requires. The person who makes the report is notified as to what action is taken. If the suggestion is impracticable or has other features which make its adoption impossible, this is fully explained and the party is satisfied.

The foregoing card system is supplemental to our safety committee, which consists of eighteen members, twelve of whom are trainmen, the others belonging to the shops, track and power departments. These men serve for a period of four months, the terms of one-half expiring each two months. This committee meets at noon on the first Tuesday of each month. We have a good lunch, and while the cigars are being smoked every man loses his reserve and gives up the best in him. A grouch simply cannot live through one of these meetings. When a man's term expires, he goes forth a more loyal man with a much broader view and a more sympathetic understanding of the difficulties of the business from the management's side.

This committee has been organized since February, 1913. In making up the report covering its first year's work last March, it was found that 90 per cent of its 244 recommendations had been adopted by the management, and it has received similar encouragement this year. Most of the recommendations are to remedy specific local conditions and would not be of general interest. This does not mean that a large percentage of the things recommended would not have been done in the old way without such a committee. It is certain, however, that many of them would not have been done. Moreover, there is a more cheerful and conscientious obedience to regulations when the trainmen have a hand in their adoption. For example, every superintendent knows how hard it is to get motormen to observe caution, slow and stop signs. At least 75 per cent of such signs on our system were placed by the suggestion of the trainmen, and they obey them because they know why they are there. They are also beginning to inquire on the outset of each recommendation, how much it costs and whether the advantage gained justifies the cost. In other words, their interest is becoming personal and intelligent and not simply routine. They are reaching a point where they can be called one of us and distinguished from the public, who seem to think that the company's cash bag has no bottom.

The idea that to develop pride in the work makes a man more industrious presupposes a spirit of contentment. A man to be contented must feel secure in his position and feel that it is worth while to make a success of it and that loyalty and industry will receive a reward. Trainmen are kept informed as to the earnings of men in other trades, and the men who have been in the service from ten to twenty years and are making it their life work are held up as examples of what a man can do as a trainman. Most of these older men own their homes, have good families and are citizens that would honor any trade. These things are referred to in our bi-weekly lectures at the trainmen's quarters. It seems that sober thought along these lines would develop professional pride. To take work well done as a matter of course and always to discipline for mistakes is, at most, only half right. An opportunity should never be missed to show that good service is appreciated. Our best men are the fellows of whom we see the least. They are never in trouble, never on the carpet. Therefore, to see these fellows, to let them know that they are not forgotten, and to encourage them by a show of appreciation is a good thing.

The promotion of harmony between departments does not mean the prevention of open hostility but the bringing about of a better understanding of the other fellow's problems. Within the last few years the claim departments have been especially aggressive in pushing their interests, and properly so; yet, while it should be nothing short of sacrilege to say a word against so manifest a humanitarian movement as "safety first," other departments have felt that in some instances extremes have been reached and expenditures have run up maintenance costs that results have failed to justify. Again, the transportation departments have felt that their province was being invaded by the attempt of the power, mechanical, track and claim departments to pass on the competency of the trainmen. The efficiency department is trying to overcome this friction by making a special study of accident prevention from all sides. It is influenced in recommending measures by the effect upon all departments concerned and by teaching the car men to be courteous, to avoid accidents, to care for the car equipment, to save power, to care for the track and overhead; in short, to produce men that are satisfactory to all.

To obtain the good will of the public it is necessary, first of all, to give good service. This we know we are doing by giving all the service that the patronage justifies. With this as a foundation, we continually keep our side of the question before the public in our column in the daily papers. It seems to be the simple matters that the public is ignorant of —things so patent that we make the mistake of concluding that everybody knows them. For example, the reason why cars are sometimes late, why everyone cannot always have a seat, why extensions and upkeep are regulated by income, and why rules and regulations are necessary for good service. It is from a misunderstanding of these small things that a great amount of popular prejudice comes. We have also become converted to the idea that we are not always right, and when a patron has a complaint this department gives it attention. If the company is at fault, we are not afraid to say so, to remedy the trouble, to apologize or do whatever else the occasion demands. Most of our enemies are made through the men on the cars. Since the public is influenced in the formation of its opinion of the company's policies by the impressions made by the car men, we are making a special effort to eliminate the discourteous car man.

The Worcester (Mass.) Consolidated Street Railway reports a decrease in the number of passengers carried recently. This it ascribes to disturbed industrial conditions, particularly in the suburban territory through which it operates.

Signals on the New York State Railways, Rochester Lines

A Remarkably Complete System of Track-Circuit Controlled Automatic Block Signals Has Been Recently Installed on the High-Speed Interurban Lines of This Company, Following Movements at Short Headway Being Permitted by Three-Position Intermediate Signals with Overlap Control

An automatic block signal system having many unusual features has been recently placed in service on both the Rochester & Eastern and Rochester & Sodus Bay lines, which are high-speed, single-track interurban railways operated by the New York State Railways. The same system of signaling is used on both lines and affords absolute blocking between passing sidings for opposing movements and protection for following movements at shorter intervals by means of intermediate signals. Three-position semaphore signals are used and overlaps are provided in all cases so that cars which may run past stop indications for the full braking distance are in no danger. Distant indications are provided throughout by having the semaphores take the clear position from the caution position of the signal in advance. Apparently nothing which will aid in providing for safe and rapid service has been omitted.

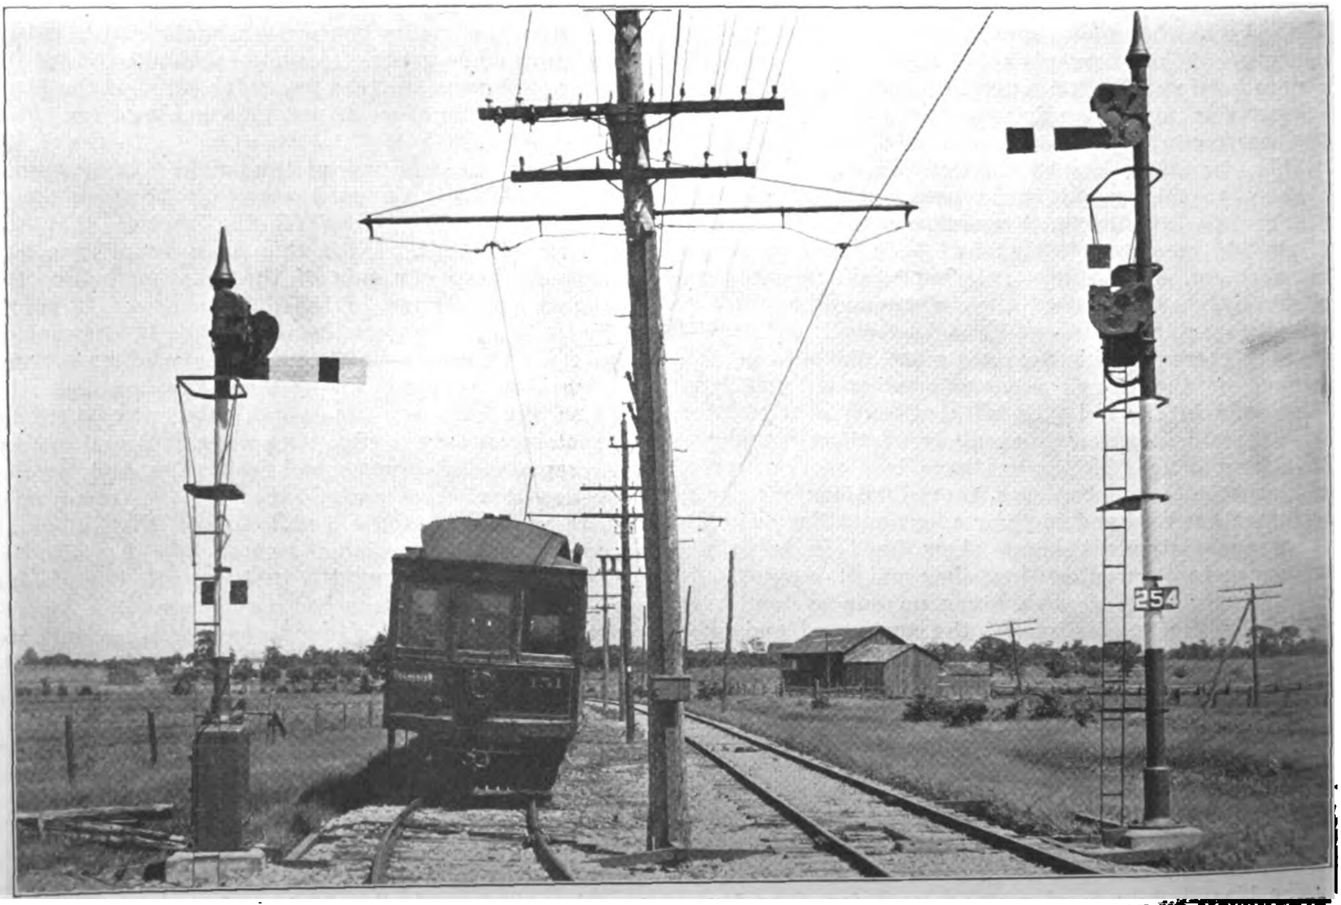
On the Rochester & Eastern line the daily traffic consists of thirty-four scheduled trains, of which four are freight trains, between Rochester and Geneva, and also nineteen scheduled trains between the terminals and several intermediate stations. The scheduled speed is 32 m.p.h. for limited trains and 22 m.p.h. for the local service. On the Rochester & Sodus Bay line the traffic consists of forty trains, including three for freight service. These trains have a scheduled speed of about 19 m.p.h. This traffic is nearly doubled on Saturdays, Sundays and holidays, when many of the trains are operated in as many as five or six sections.

Each line is about 40 miles long. In most cases the sidings are single-end, but there are several double-end sidings and several stretches of double track, varying in length from a quarter of a mile to a mile and one-half. The average distance between passing sidings is approximately 2 miles.

The switches of the single-end and double-end sidings are equipped with rigid or non-automatic switch stands and are normally locked in the main line position. It is the practice at these sidings for a car to run by, back in and head out or to head in, back out and proceed, depending on the direction of the train.

The switches at the ends of the double track stretches are equipped with spring or automatic switch operating mechanisms and the switch points are normally set for right hand movements—for the turnout at one end of the double track and for the main line at the other end, as it is the practice for cars to run through to the right on these stretches.

All switch lamps are equipped with two 12-volt, 5-watt tungsten electric lights, connected in multiple, which re-



ROCHESTER SIGNALS—VIEW OF SIGNALS INSTALLED AT END OF LONG SIDING TO PROVIDE FOR CLOSE-UP MOVEMENTS SHOWN ON RIGHT-HAND MAST ceive energy from a line transformer located at each switch.

SIGNAL SYSTEM

The signals are arranged according to the General Railway Signal Company's absolute-permissive block system, so named because it affords absolute blocking between passing sidings for opposing train movements, in which case the block is the distance between adjacent passing sidings, and permissive or standard double track blocking for following movements, in which case the block is from signal to signal. This materially increases the factor of facility without diminishing the factor of safety.

The signal arrangement provides starting signals which are located at the passing sidings and govern train movements in their respective directions, with one or more pairs of intermediate signals between sidings. Signals governing movements in the same direction are approximately 4000 ft. apart. Overlaps were incorporated in the system in the interest of "safety first," and the starting signals are staggered accordingly. Signal indicators are located at stub-end passing-siding switches to repeat the indications of the signal in the rear. Switch indicators are also located at intermediate switches to indicate the condition of the blocks in both directions, and switch circuit controllers, through which the signal control circuits were broken, are located at the switches. Both rails are used for the return of the d.c. propulsion current.

A typical signal arrangement was published in the ELECTRIC RAILWAY JOURNAL for Oct. 4, 1913, page 620. With two pairs of intermediate signals, the overlap is 800 ft., or the safe braking distance. The stop control of the intermediate signals extends to their respective, opposing, starting signals at the ends of the block. This arrangement makes the block for opposing movements from siding to siding and insures a stop indication at an intermediate signal if an opposing train has passed the opposite starting signal. For following movements the block is from signal to signal.

With only one pair of intermediate signals, the overlap at the intermediates is 1500 ft., which represents the safe braking distance for two opposing trains. If a condition occurred in which, for example, a west-bound train entered a block then occupied by an east-bound train, it would still be necessary for one or both trains to pass a stop indication at the intermediate signal before a collision could result, and, even if both trains simultaneously approached the signals at high speed but applied the brakes at the respective intermediate signals the trains would come to a stop before colliding.

ROCHESTER SIGNALS—MAP OF ROCHESTER INTERURBAN LINES, NEW YORK STATE RAILWAYS

In the block at the beginning or end of a section of signalled territory there are no intermediate signals, and to maintain the high degree of safety the signal at the beginning of the signalled territory is so arranged that it normally indicates stop. The opposing signal normally indicates caution, as there is no signal in advance governing movements in the same direction. The control of the opposing signals is interlocked so that only one can display a proceed indication at one time. A train approaching the normal stop signal en-

ROCHESTER SIGNALS—SIGNAL MECHANISM

ters a short preliminary track section, which causes the operation of the normal-caution signal and the display of a proceed indication, provided the block is unoccupied and that the opposing signal is in the stop position.

USE OF THE TELEPHONE

Train orders, messages and miscellaneous company business are transmitted by means of the telephone, which also performs an important service in connection with the signal system, as trainmen can communicate with the dispatcher at each signal.

The rules prescribe that a stop signal must not be passed except under authority of a train order issued by the dispatcher. For communication with the dispatcher, a portable telephone set with flexible cord attachment is mounted in the motorman's compartment of each car, and connection to the telephone line is obtained by means of two jacks which are mounted on the first transmission line pole in the rear of each signal. These jacks connect with duplicate telephone circuits, one of which is ordinarily used as a dispatching circuit for the transmission of train orders and other orders affecting the movement of trains; the other circuit is ordinarily used for miscellaneous company business. The motorman can make a connection through the car door and can talk with dispatcher without leaving his compartment. The flexible cord when not in use is wound on a reel which forms a part of the telephone set.

If a train on single track meets a stop signal and communication with the dispatcher cannot be obtained the rules permit a train to pass the stop signal and flag through block in accordance with the old flagging rules. A time-table rule requires that all trains must report at certain stations and receive either a train order or a clearance card before proceeding.

The fouling point or end of track circuit at passing sidings and other turnouts is marked by a wrought-iron pipe post which stands back of the insulated joint so that trainmen can see that their cars are clear of the fouling point, as prescribed by the rules. This point is worthy of note as trainmen frequently allow cars to stand on the fouling section where there is no post or sign, and so-called signal failures result.

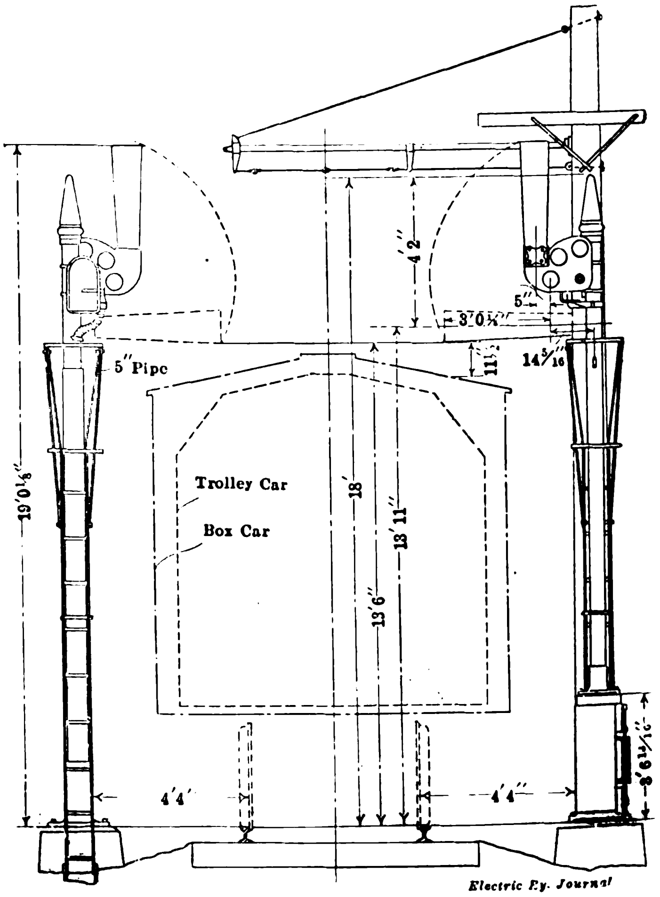
Signal indicators are installed at passing siding switches to repeat the indications of the signal in the rear. The signal indicator at a siding repeats the indications of the starting signal to the rear signal, and a train on the siding observes the indicator instead of the starting signal, which is approximately 900 ft. in the rear of the switch. Signal indicators are of the semaphore type and operate in two positions. The 45-deg. position indicates that signal is in the clear or caution position, and the horizontal position indicates that signal is in the stop position. Switch indicators are of the disc type and show a red disc when the block is not clear.

Normally, signal and switch indicators display proceed or clear indications, but the rules require the operation of a test push button on the indicator case before the indication can be accepted. If the push button is operated when block is clear the indicator arm or disc moves to stop position, but returns to normal position when released. If block is not clear, the indicator arm or disc remains in the stop position. The push button shows when indicator is in proper working order and thus materially increases the efficiency of the device. The word East or West is painted on each indicator case, according to the direction which the indicator governs.

All switches are equipped with switch circuit controllers. Circuits controlling operation of the signals are broken through the switch circuit controllers and, as the controller contacts are operated by a connection to the switch points, adjustments can be made so that a clear signal cannot be displayed unless the switch is in proper main-line position.

SIGNALS

The installation makes use of the General Railway Signal Company's Model 2A, top-of-mast, electric motor, semaphore signals, which operate in three positions and display the indications in the upper left-hand quadrant. There are also several light signals which were installed where the low hanging branches of trees would interfere with an operative semaphore signal. The signals are equipped with 110 volt, single-phase, twenty-five-cycle induction motors. This motor is in reality a two-phase motor arranged to operate on single-phase cur-



Electric Ry. Journal

ROCHESTER SIGNALS—LOCATION OF SIGNALS WITH CLEARANCES FOR STANDARD EQUIPMENT rent by means of an impedance which is connected in series with one of the windings in order to obtain the necessary phase displacement. Both windings are in service while the motor is operating, which eliminates the necessity of contacting devices such as are ordinarily used with single-phase motors to interrupt the current through the starting winding after motor has developed its normal speed.

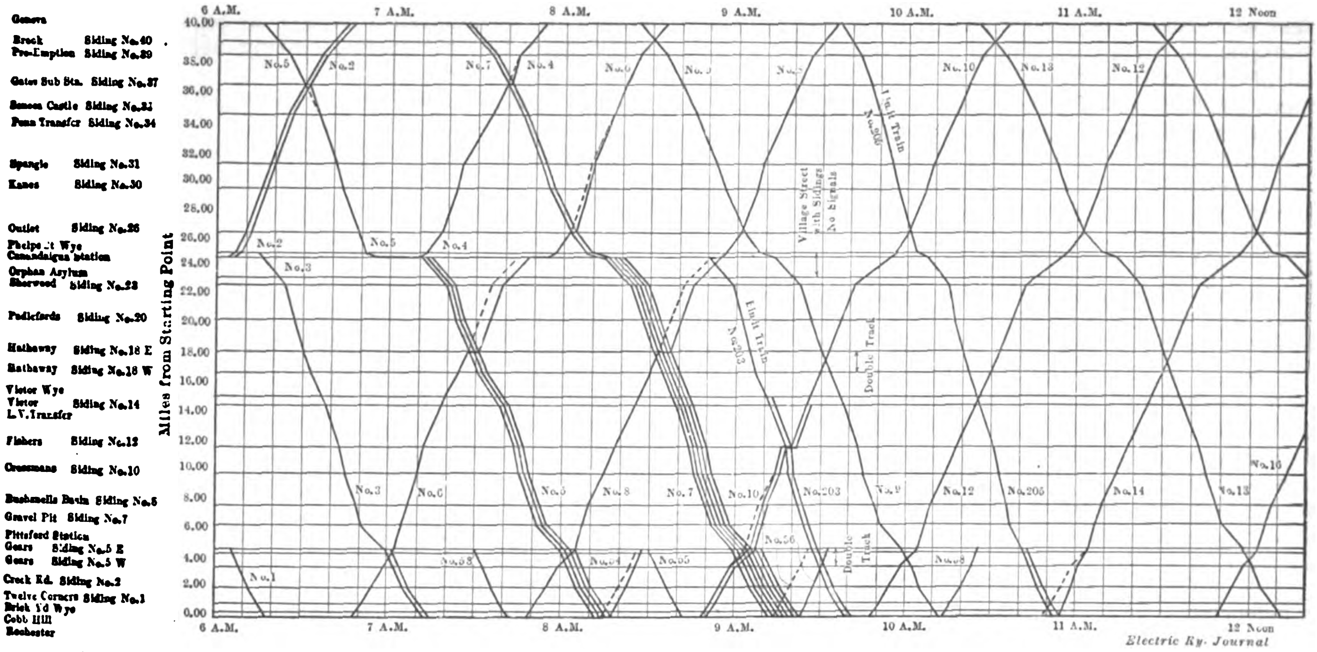
The semaphore arm is held in the caution and clear positions by means of a stator winding and a laminated iron core or rotor. The rotor is loosely mounted on the armature shaft and operates in connection with a clutch. The rotor does not revolve with armature shaft when the operating windings are energized, but when semaphore arm is moved to the caution or clear position the stator windings are energized, the clutch becomes effective, the magnetic attraction between the poles of rotor and stator prevents rotation of the armature shaft and holds the signal arm in the proper position. When the holding circuit is broken, the stator windings are de-energized which releases the rotor and the semaphore arm returns to the caution or stop position by gravity.

The standard signal has a square-end blade, the front of which is painted red with white stripe and the back white with black stripe. From foundation to top of relay box, the signal mast is painted black, from there to the mechanism case the mast is painted white, and above this point black. Each signal mechanism is equipped with two Veeder counters which register the number of semaphore movements. One registers the number of caution or 45-deg. movements, and the other the proceed or 90-deg. movements.

There are several stations where it is frequently necessary, in "closing up" trains, to permit two or more trains to occupy the same block in order to avoid delays. To provide for this condition, the management adopted a special two-arm signal of which the upper arm constitutes the main indication and a lower or calling-on arm the restricted indication. When used on double track stretches the upper arm is non-operative, being fixed in the horizontal or stop position. The lower arm operates in three positions and normally is vertical, indicating "proceed at medium speed," but when block is occupied, the lower arm is in the 45-deg. position, indicating "proceed at slow speed prepared to stop short of any obstruction." When switch is in wrong position the lower arm is horizontal, indicating stop.

When used on single track, the upper arm operates in three positions and the lower arm in two positions, horizontal or zero position to 45-deg. position. When the upper arm displays a proceed indication (clear or caution), the lower arm is in the horizontal position and a train proceeds on authority of the upper arm. When the block is occupied, the upper arm is in the horizontal position and lower arm is in the 45-deg. position, indicating "proceed at slow speed prepared to stop short by any obstruction," as on double track.

The semaphore signals are electrically lighted by two 12-volt, 5-watt tungsten lamps which are connected in multiple and receive energy from a 9-volt tap on the line transformer. The operation of the lamps below their rated voltage affords ample illumination and materially increases the life of the lamps. The light signals are electrically lighted by two 40-watt tungsten lamps which are connected in multiple and receive energy from a 55-volt tap on the line transformer. The electric lights require practically no attention and have been known to give good service for more than a year, thus reducing the cost of lamp maintenance and affording an efficient and economical method of signal lighting.



ROCHESTER SIGNALS—TRAIN SCHEDULE DIAGRAM SHOWING EFFECT OF SIGNAL ON ORIGINAL SERVICE

INSTALLATION

The signals and signaling appliances were manufactured and installed by the General Railway Signal Company, of Rochester, N. Y. Material for the transmission line, also the insulated joints and power bonding material, was furnished and installed by the railway company's forces. Material for insulating switches was furnished by the signal company and installed by the railway company. The installation work was performed under the supervision of C. L. Cadle, electrical engineer New York State Railways.

The government of the province of Mendoza, Argentina, has sent to the Legislature a sixty-year franchise which it proposes to grant to Anastasio Lopez & Company for the building of a rural tramway system, either steam or electric. Under the proposed franchise passenger and freight tariffs are subject to government approval, and provision is made for the government to acquire the lines after thirty years.

Convention of the Railway Signal Association

The Nineteenth Annual Convention Was Held at Bluff Point, N. Y., Sept. 22-24, 1914—Numerous Reports of Committees Were Presented and Discussed, Including Those on Electric Railway and Alternating Current Signaling and on Signaling Requirements for Electric Railways

The annual convention of the Railway Signal Association was held at Bluff Point, N. Y., on Lake Champlain, Sept. 22-24, 1914. At this meeting the reports from a number of committees were received and discussed, and several of these were of special interest to electric railways. Among them was the report of the committee on signaling practice, to which had been assigned the work of recommending an aspect for instructing trains to take siding at non-interlocked switches. The committee stated that the principle that the association was asked to pass upon was the display of a disc with the words "Take Siding" printed upon it when it was desired that a train should get into the clear at locations not controlled by interlocking plants. A suggested design which was reproduced in the *Journal* of the Railway Signal Association for June, 1914, pages 205-206, contemplated the illumination of the sign by reflected light because this had been found to be the most practicable method yet developed. However, there was nothing in the suggested aspect to prevent its illumination by transmitted light if a satisfactory way could be found to do this. Several aspects were now being used, but they differed from that suggested to the extent that sometimes a letter "S" and sometimes the word "Siding" was used. The suggested sign was to be displayed only when a train was to side-track and the device could be operated by any convenient means. Only one application of the principle was suggested, but the committee stated that, next year, if this aspect was approved other applications would be presented for the approval of the association. In conclusion it was recommended by the committee that the suggested aspect should be submitted to letter ballot as a standard of the association.

This committee also had been assigned the work of investigation and report on automatic train control, and the committee submitted in its report the findings of the American Railway Association at the meeting in May, 1914, as a revision of the requisites now included in the manual of the association. These findings were reported in abstract in the ELECTRIC RAILWAY JOURNAL for May 23, 1914, page 1150. The committee had been requested to confer with the special committee on signaling requirements of electric railroads, recommending modifications deemed necessary to meet the peculiar requirements and conditions for the signaling on electric railways. The committee reported progress in this work.

The special committee formed to develop a method of recording signal performance submitted several record forms. These included blanks for the use of trainmen in reporting signal interruptions, for the use of dispatchers in recording the information transmitted by this form, for the use of maintainers in reporting the causes of signal interruptions, for the use of signal inspectors or maintainers in recording and reporting monthly the number of signal operations and for the use of signal engineers and supervisors in making monthly and annual reports. Regarding the latter it was stated that any amount of detail could be incorporated and modifications made to cover special conditions without material deviations from the basic design. Details were suggested for guidance in printing this form, these to be modified to suit the requirements of systems as determined by existing conditions. This detailed information to be incorporated in the forms was as follows: Miles of road signaled; number of signals and types; signal movements; trains operated; trains delayed by signals; track department; power department; signal department; motive power department; transmission department; operating department; defective system or manufacture; miscellaneous; summary.

The committee's report also included some general instructions which were as follows:

1. Parts of apparatus broken on account of improper design or workmanship should be sent to .... office with full statement, stating serial number and manufacture.

2. Remarks column should be freely used to insure explanation.

3. Black ink, or, if typewritten, reversed carbon back of sheet, should be used, so that blueprints may be taken from the sheet.

4. Fifty per cent of interruptions, classified as unknown, may be charged to creditable stops.

5. When the counter reading of a signal, as compared with the readings of adjacent signals, seems to be in error and no reasonable cause can be attributed, the reading of adjacent signals will be substituted. A signal, however, protecting a number of switches, may make more movements than adjacent signals, in which case the readings shown should be used, as the signal has been making proper movements and should be so credited.

6. In the event of an interruption to a power supply or transmission line affecting a number of signals, only one interruption will be charged against maintenance, but an interruption for each signal affected will be charged against operation.

7. In computing efficiency, the following items may not be taken into account: Creditable interruptions; false proceed indications; lamps out.

The committee stated that a number of railroads were delaying the adoption of signal performance report forms pending the action of the Railway Signal Association toward the adoption of standards. The majority of replies in circular letters indicated that this report contained satisfactory material for their use and that they were willing to try it. The committee realized that the forms, if used, might be subject to further development as determined by service requirements and might be the means of harmonizing the present widely diversified practices. Therefore the members of the committee unanimously recommended the submitting of this report to letter ballot for adoption.

The standing committee on electric railway and alternating current signaling had been given the following assignments: *a*, Continued investigation of the various systems in operation; *b*, prepare specifications and requisites for apparatus and materials for a.c. block signal systems; *c*, investigate the inductive effects between the signal circuits and adjacent electric circuits and formulate recommendations; *d*, investigate the hazards due to the paralleling of high tension and low tension lines.

The committee, of which C. H. Morrison is chairman, presented under subject *a* a number of descriptions of various a.c. signal installations. In connection with assignment *b* a number of specifications on different classes of material were presented. It was stated that considerable time had been spent in investigating assignment *c*, but on account of the difficulty experienced in collecting information the committee could only report progress at this time. Progress was also reported on assignment *d*, and there were submitted specifications for overhead crossings of electric light and power lines which when complied with would greatly reduce the hazard of high-tension crossings.

A majority of the descriptions of existing a.c. installations on electric railways which were presented by the committee have already been published in previous issues of the ELECTRIC RAILWAY JOURNAL, the Piedmont Traction Company installation being the one exception. Regarding this the committee stated that the signaled section was between Charlotte, N. C., and Hoskins Yards, N. C., a distance of approximately 4½ miles. There were seventeen signals and six switch indicators, the material having been furnished by the Union Switch & Signal Company. The line was double tracked for 3½ miles and had a single track at one end approximately 1 mile in length. Indications were given by means of lights backed up by large hoods, the operation being controlled by track circuits with sixty-cycle, single-phase signaling current. Distant signals were generally used, being erected at points which ranged from 1200 ft. to 1600 ft. in the rear of home signals.

In the specifications submitted by this committee it was stated that the use of oil in impedence bonds could not be recommended. Petrolatum was recommended instead. This should be a pure mineral oil, free from acid, alkali and other chemicals, with a melting point between 120 deg. Fahr. and 130 deg. Fahr. Specifications for transformer oil and alternating-current electric generators were also submitted, as was a revision of the specifications for overhead crossings of electric light and power lines. In connection with revision of existing specifications the committee stated that track relays receiving all of their energy from the track rails should consume not more than 20 volt-amp with a power factor of 54 per cent at 3 volts. Relays receiving part of their energy from the track rails and part from another source with the two currents in quadrature relation should consume not more than 1.6 volt-amp with a power factor of 6 per cent at 1.3 volts from track, with not more than 11 volt-amp unity power factor at 110 volts taken from the other source.

The committee on wires and cables presented elaborate specifications for galvanized messenger wire, including a series of tables of recommended sags for messenger wires and showing sizes and strengths that should be used to support cables of various weights and spans. In connection with these tables the committee called attention to the apparently excessive sags required by the tables. As the correctness of the formulas and calculations were evident to the committee, it followed from an examination of sags of cables now in place that the method of erection used in the past (consisting principally of pulling the wire as tight as the line foreman deemed proper), had resulted in the wires being drawn too tight. Sufficient sag was not allowed to give a reasonable factor of safety if a man was required to ride the cable.
